SIR,—During a recent journey on the Continent, I had the pleasure of inspecting a coal-testing station near Brussels, which interested me very much. I also witnessed a test; and thinking that your readers may like to know a little about it, I subjoin a few notes.

At this station the coals supplied to the Government Railways by the various contractors are tested daily for their evaporative power, in a precise and scientific way, by means of locomotive boilers. If the coals do not come up to the necessary standard, the contractors are either fined or the coals not accepted. In this way, some thousands of tests have been made with every variety of coal, and much valuable data obtained; so that the State know much more about their coal than we do with our English coal.

The whole station seemed to me to be well arranged for prompt, accurate, and practical results.

I am anxious to find out whether in other countries there are any similar coal-testing stations, worked either by the large Railway Companies or Marine Departments of Foreign Governments. Perhaps some of your Continental readers would kindly enlighten me as to this. I am informed that the Railway Companies in France and Germany do not test their coal for its evaporative power in a methodical way; and the same want of any experiments is to be regretted in England.

Bermondsey, Nov. 8, 1888.

BRYAN DONKIN, JUN.

[ENCLOSURE.]

Notes on the Belgian Station for Testing the Evaporative Power of Coal used on the Locomotives of the State Railways.

The coals suitable for the grates of the locomotives are divided into four categories, and must be capable of evaporating (depending on the quality) from $4\frac{1}{2}$ lbs. to $7\frac{1}{2}$ lbs. per pound of coal. The tests are made at a station especially installed for the purpose; and the above quantities of water have to be evaporated at pressures varying from 90 lbs. to 120 lbs., and the coal supplied must be able to keep up this pressure.

The contractor must supply about $\frac{1}{2}$ ton for the trials. The draught is produced in the usual way from a locomotive, by a steam jet in the chimney; and it is varied according to the quality of the coal, from $2\frac{1}{2}$ to $4\frac{1}{2}$ inches (water pressure).

The contractor may be present during the trial. Only a certain percentage of incombustibles is allowed; and the average size of the coal is also accurately defined—that is to say, the coal is not accepted unless 25 per cent. is of certain fixed dimensions. The water evaporated is carefully measured in long tanks; and the locomotive boilers and grates at the station are exactly similar to those used on the State Railways.

THE GAS-WORKS AT THE HANWELL SCHOOLS.—The question of the manufacture of gas at the Central London District Poor Law Schools at Hanwell, to which reference was made in the JOURNAL for the 23rd ult., was again the subject of a discussion at the meeting of the School Managers yesterday week. The Clerk (Mr. East) read a report of the Farm Committee, to the effect that Mr. Broadberry's letter had been considered, and that estimates had been obtained for removing the present iron retorts from one of the arches, and substituting clay retorts, as suggested by that gentleman. The Committee recommended the Managers to accept the estimate of Messrs. J. and H. Robus for the work, and that Mr. Broadberry be employed to inspect it while in progress. On this report there was a long discussion, in the course of which it was stated that, since the estimate was obtained, Mr. Broadberry had given the Committee to understand that the sum mentioned would not cover the cost of the necessary works. Mr. Cooksey objected to the Committee taking action to have the gas-works continued in operation before the Managers had determined whether or not they would go on making gas, or purchase it from the Brentford Gas Company, who had offered to supply the schools. Mr. Dunn said the Committee would not bind the Managers to any expenditure before this question had been determined. He, however, desired the Managers to know that if they could manufacture gas at the price given by Mr. Broadberry (2s. 7d. per 1000 cubic feet), they would save £120 per annum. Eventually the report was referred back to the Committee to obtain full particulars as to the cost of the necessary works.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

FRIDAY, NOV. 2.

(Before Mr. Justice Kay.)

In re THE ARBITRATION BETWEEN THE YEADON LOCAL BOARD AND THE YEADON WATER-WORKS COMPANY.

This was a motion by the Yeadon Water-Works Company to set aside the award made in an arbitration between themselves and the Local Board of Yeadon. The circumstances under which the arbitration took place will be in the recollection of our readers; but it may be of interest to recapitulate them, as follows:—The Company, which had previously existed as a limited liability undertaking, was, in 1870, incorporated by Special Act of Parliament. In 1887, owing to the great drought in the summer of that year, the Company had much difficulty in supplying their district with water. In July, 1887, the Local Board asked the Company whether they would be willing to sell their undertaking to them, and, if so, on what terms. This application was followed by a formal notice from the Board, under section 52 of the Public Health Act, 1875, requiring them to supply each house in the district with water, suitable and proper for drinking and ordinary domestic purposes, at the rate of not less than 20 gallons per head per day. The offer for purchase was declined by the Company, who insisted that they were using their utmost endeavours to maintain a sufficient water supply. Ultimately, in December, 1887, the Board served the Company with notice of the appointment of an Arbitrator, under sections 179 and 180 of the Public Health Act; the notice setting forth that the matter to be dealt with by him was "a difference as to whether the water which the Company are able and willing to lay on is proper and sufficient for the purposes for which it is required within the district." Thereupon the Company appointed an Arbitrator on their side. On Jan. 3, 1888, the Arbitrators had a meeting; but nothing was done, beyond extending the time for making the award, until Feb. 20. On Jan. 10 the Arbitrators again met, and appointed an Umpire. On Feb. 1 the Arbitrators and the Umpire held their first meeting, and were attended by the Solicitors for both parties. The Solicitor for the Company endeavoured to limit the scope of the inquiry to the question whether the Company were bound to supply 20 gallons of water per head per day, according to the original notice; but the Solicitor for the Local Board objected to this limitation. Thereupon the Company's Solicitor withdrew, and took no further part in the proceedings. The meeting was then adjourned *sine die*. On April 19 last, notice to attend having been given to both sides, the Umpire made his award (the Company not being represented on the occasion), determining that the Company were not able and willing to supply water proper and sufficient for the purposes set out in the original notice, or for the requirements of the Local Authority therein mentioned, and also that the purposes for which water was required under the notice were reasonable; and he ordered the costs of the reference and award to be paid by the Company. The Company then served the present notice of motion to set aside the award on various grounds, especially on two—viz., (1) that the award had not been made within the time required by the Public Health Act; and (2) that the main question whether a supply of 20 gallons of water per head per day was reasonable had not been gone into by the Umpire. From evidence given by the Umpire, there seemed to be some doubt whether he had considered this question specifically.

Mr. RENSCHAW, Q.C., and Mr. EYRE appeared for the Company; Mr. MARTEN, Q.C., and Mr. F. T. PROCTOR for the Local Board.

Justice KAY, in giving judgment, said the first objection to the award—viz., that it was not made within the time required by the Public Health Act, 1875—depended on section 180, sub-section 9, which provided that "the time for making an award by an umpire under this Act shall not in any case be extended beyond the period of two months from the date of the reference of the matter to him." The question was, What was he (Justice Kay) to take as the "date of the reference" to the Umpire? There was no evidence before him to satisfy him that there was any reference to the Umpire, as distinguished from the Arbitrators, before Feb. 20; and, accordingly, the award was made within the two months allowed by the Act. He therefore could not accede to the objection on the point of time. The other objection was one of more difficulty. The 52nd section of the Public Health Act, under which the arbitration had been conducted, was in these terms: "Before commencing to construct water-works within the limits of supply of any water company empowered by Act of Parliament, or any Order confirmed by Parliament, to supply water, the local authority shall give written notice to every water company within whose limits of supply the local authority are desirous of supplying water, stating the purposes for which and (as far as may be practicable) the extent to which water is required by the local authority." Two things were required to be stated in the notice—viz., the purposes for which water was required by the local authority, and (as far as might be practicable) the extent to which it was required. Now, the purposes and the extent were both stated in the original notice given to the Company. Then the section proceeded: "It shall not be lawful for the local authority to construct any water-works within such limits if and so long as any such company are able and willing to supply water proper and sufficient for all reasonable purposes for which it is required by the local authority; and any difference as to whether the water which any such company are able and willing to lay on is proper and sufficient for the purposes for which it is required, or whether the purposes for which it is required are reasonable, or (if and so far as the charges of the company are not regulated by Parliament) as to the terms of supply, shall be settled by arbitration in manner provided by this Act." Now, it would be observed that the extent to which the authority in question required the water was not one of the matters to be settled by arbitration, nor was the reasonableness of the extent one of the matters to be submitted. That which was to be submitted was the ability of the Company to supply water which was proper for all reasonable purposes, their ability to supply water which was sufficient for those purposes, and their willingness to supply it for those purposes. The reasonableness might be left out of consideration in the present case, because as to this there was no question. His Lordship then went through the evidence in the case and the award, and said it was clear that the Company were not in a position to comply with the requirement to supply 20 gallons of water per head per day, or anything like it. They were actually supplying only about 4 gallons per head per day to their customers; and, according to the report of their own Engineer, they were not in a position to supply more than $8\frac{1}{2}$ gallons. There was no attempt on the part of the Company to prove before the Umpire that 20 gallons a day were not required; but ample evidence was given that this was a reasonable quantity. The Company did not bring forward evidence on the subject, because they knew they could not supply 20 gallons a day. In his Lordship's opinion, this was an attempt on the part of the Company to get rid of the effect of an award which was quite reasonable, had been properly made, and was free from irregularity or mistake, so far as he could make out; and therefore the motion must be refused, with costs.

HIGH COURT OF JUSTICE—QUEEN'S BENCH DIVISION.

MONDAY, OCT. 27.

(Before the LORD CHIEF JUSTICE and Mr. Justice GRANTHAM.)

THE QUEEN v. THE JUSTICES OF CHESTER.—LIABILITY FOR DAMAGING A PUBLIC LAMP.

This case raised a novel point as to the liability for damage to a gas-lamp, and came before the Court in the form of a motion to make absolute a rule nisi granted in June last (see JOURNAL Vol. LI., p. 1156) for a *mandamus* to the Justices of Chester to state a case for the decision of the High Court of Justice; the application being made on behalf of the Chester Gas Company.

Mr. MARSHALL, who appeared to show cause against the rule, stated the facts of the case, as follows:—A person named John Challoner was sued by the Company to recover £3 for damages to a gas-lamp. The defendant's son was, on the 27th of April, moving a load of furniture, when, on going down a hill, a portion of the harness broke, and the horse, becoming unmanageable, ran against a lamp-post and broke it. An information was laid under the 20th section of the Gas-Works Clauses Act, which renders any person causing damage to property of a gas company liable to a penalty not exceeding £5. The Justices, after hearing evidence, dismissed the case—the Chairman stating that the wrong person had been brought before them; and upon an application being made to state a case, they refused, on the ground that it was frivolous. This was all that took place in open Court; but the Justices had made an affidavit in which they stated that they had considered the whole of the facts, and that their decision was based upon the entire case—the statement of the Chairman that the wrong person was brought before them being only one point in the case. They were satisfied, from the evidence, that Challoner was not responsible for the accident, as he was not in charge of the horse; and the harness broke, not through any defect, but through the steepness of the hill down which the boy was driving. Further, the Justices were satisfied that the boy in charge of the horse was not responsible, as he had lost all control over the animal. They also found that the lamp-post was not fixed at the proper distance outside the kerbstone. Counsel from these statements argued that if anybody was responsible it was the Local Authority or the Company themselves; and the section under which the information was laid required to sustain a conviction that the damage should be done by some "person," which was not the case here, as shown by the affidavit of the Justices.

Mr. FULLERTON, who appeared for the Company, contended that the statements made in the affidavit of the Justices had no foundation in fact or in law, and were in themselves absurd. It was hardly necessary for him to point out that harness must be defective if it were not strong enough to enable its wearer to take its load up; or down the hill; but he might mention that the Company had no choice in the selection of the places where gas-lamps were erected. They had to be erected in whatever places were ordered by the Local Authority. The question was a most important one in the public interest; and he hoped their Lordships would therefore order the Justices to state a case.

After some further argument, their Lordships made the rule absolute.

WEDNESDAY, OCT. 31.

(Before Justices FIELD and WILLS.)

THE QUEEN v. THE STAINES LOCAL BOARD.—THE SEWAGE POLLUTION OF THE THAMES.

This was an indictment for polluting the River Thames by allowing sewage to pass into it; the prosecutors being the Thames Conservators. The case was tried in February last, before Baron Huddleston,* when a special verdict was found; and on this the matter now came on for argument.

Mr. CRUMP, Q.C., and Mr. BANKS appeared for the Conservators; Sir HENRY JAMES, Q.C., and Mr. TINDAL ATKINSON for the Local Board.

Mr. CRUMP said the proceedings were taken under sections 64 and 65 of 29 and 30 Vict., c. 83, which was known as the Thames Navigation Act, 1866. The first of the above sections provided that where any sewage or other offensive matter is caused or suffered to flow into the Thames, or into any river or water-course connected with the Thames, the Conservators, within a reasonable time after knowledge of the fact, should give notice in writing, under their common seal, to the person or body causing or suffering the same, requiring him or them to discontinue the flow within a certain specified time. By the 65th section, if, after reasonable notice, the persons causing or suffering the flow of noxious matter did not discontinue the same, they were guilty of a misdemeanour, and were liable to an indictment. In September, 1879, notice in the form prescribed was given to the defendants, which was not complied with; and, in the years 1881-4, proceedings were taken against the Local Board, and they were then convicted and fined on each accusation. These convictions and the imposition of the penalties not having had the desired effect, the Conservators indicted the Local Board. A true bill was found by a Special Grand Jury; and on the case coming on for trial before Baron Huddleston, by agreement between Sir Henry James and himself, the facts were stated in the form of a special verdict. The learned Counsel then proceeded to read the special verdict, the important point of which was that certain persons in Staines had acquired a prescriptive right to drain into the sewers, which eventually led into the Thames, if such right could be acquired in law. The contention of the prosecution was that the drains and sewers were vested in the local authority, who had complete control over them; and even conceding that owners of houses and tenements had a right to discharge sewage into the drains, this did not affect the liability of the Local Board in respect of the outfall of the main drain into the Thames. The nuisance complained of was not the passing of sewage into the drain by the owners of houses, but the passing of the sewage into the Thames. The Board had power under the Public Health Act to block up any sewer on providing another equally convenient.

A discussion arose as to whether the terms of the special verdict were complete and satisfactory to both sides; and learned Counsel having expressed their satisfaction with them, the further hearing was adjourned.

THURSDAY, NOV. 1.

Mr. CRUMP resumed his argument this morning, and submitted that no prescriptive right was proved so as to cover the offence. There could be no prescription in the face of the Act of Parliament, as was laid down in "Goddard on Easements," and shown by the case of the *Rochdale Canal Company v. Radcliffe*.

Justice FIELD pointed out that the prescription in this case was of a different nature to an easement resting on an implied grant. There it was a case of immemorial usage. He knew that some of the houses in Staines, or one at any rate, dated back to 1646.

Mr. CRUMP submitted that any such right could be put an end to by Act of Parliament, and that this had been done by the Act of 1866.

Justice FIELD remarked that no doubt Parliament could take away a man's rights, even without compensation; but he had never known such a case.

* See JOURNAL, Vol. LI., p. 428.

Mr. CRUMP said the right to use any drain was subject to the powers of the Sanitary Authority to stop up the drains under the Public Health Act, section 64. Any right to pass sewage into the Thames which might have been acquired by usage was determined on the passing of the Act.

Justice FIELD observed that in the special verdict he did not find it stated as a fact that the respondents had committed any offence. The Court had no power to draw inferences on a special verdict. It was stated that the respondents had not passed any foul matter themselves, or consented to the passing of any foul matter.

Mr. CRUMP said that the Board had failed to discontinue the flow on receiving notice, and had been convicted repeatedly of this offence. He submitted that the special verdict did in effect find that the offence had been committed.

Justice WILLS pointed out that it had been held in similar cases that the proper remedy was by *mandamus*, and not an injunction.

Mr. CRUMP said an injunction was a totally different remedy. He knew the cases to which his Lordship referred, and which his friend relied on; but he should distinguish them on the ground that an injunction was a matter in the discretion of the Court, whilst an indictment for misdemeanour varied the simple question whether the offence mentioned in the Act of Parliament had been committed. The cases referred to were *Glossop v. The Heston and Isleworth Local Board*, and *The Attorney-General v. The Guardians of the Poor of Dorking*, in which private persons sought to obtain relief; and on the question of the balance of convenience and inconvenience, an injunction was refused. He asked for judgment that the Staines Local Board had committed an offence; and it was not open to the defendants, under such a proceeding, to argue that it was inconvenient, expensive, or even impossible, to carry out works which would prevent the nuisance. They simply sheltered themselves under the alleged prescriptive rights of the owners of houses. He submitted that this was no answer to the case; and that judgment must be entered in accordance with the special verdict, that the defendants were guilty.

Sir H. JAMES submitted that on the verdict the defendants were entitled to be found not guilty. This was a criminal charge; and Mr. CRUMP's argument was that, if one man could prevent another committing an offence, and did not do so, he committed it himself, and this had been discredited from in express terms by a very high authority. It might strike the Court that if the river was being polluted, there ought to be some means of preventing it. This was given by the 6th section of the Act; and the Conservators, who were the body having this duty cast upon them, and having large funds for the purpose, ought, if their contention was right, that no prescription could exist to send sewage into the Thames, to proceed against those persons who were creating the nuisance, and not against the Local Board, who, he contended on authority, had no power to stop it. If they wished to force the Local Board to provide a better system of drainage, they ought to proceed by *mandamus*, in which case the Board would be entitled to show what they had done, or were doing, to carry out the duties imposed upon them.

Justice WILLS observed that he did not understand why the Local Board had not required the Conservators to prosecute the persons who sent down the sewage.

Sir H. JAMES said he was instructed that they had done so. This was an indictment for a criminal offence; and before they could be convicted, it must be shown that they had caused or suffered noxious matter to flow into the Thames. It was true that, under the Public Health Act, the sewers were vested in the defendants; but that was only a qualified vesting, as was laid down by Sir George Jessell in the Dorking case. He said there that this vesting only gave them a qualified ownership, subject to the rights of any other persons to make use of the sewers. Under this indictment, if the Local Board had spent hundreds of thousands of pounds in endeavouring to provide a perfect system of drainage, it would be no answer at all—in fact, there was no evidence before the Court that the Local Board were not constructing works at the present moment. The learned Counsel then quoted passages from the judgment of Sir George Jessell in the Dorking case, in which it was laid down that a local authority was not bound to bring an action to prevent a person having a prescriptive right to send sewage through sewers vested in them from doing so, and further expressed the opinion that such an action would fail if brought. He also referred to the case of *Glossop v. The Heston and Isleworth Local Board*, and submitted that judgment must be for the defendants.

Mr. CRUMP, in reply, said the remedy which the Conservators were seeking to enforce was the one pointed out by the Act of Parliament. It was not for them to apply for a *mandamus*. They had nothing to do with providing for the drainage of Staines, or any other district. Their functions were defined by the Act, and were confined to preventing the entry of polluting matter into the river. They found such matter coming into the river from sewers vested in the Staines Local Board; and, in accordance with the Act, they had given them notice to discontinue such flow within a reasonable time—viz., thirteen months; and this not having been done, and having taken summary proceedings on several occasions, when the defendants pleaded guilty, and fines were imposed, and the nuisance still continuing, they had no alternative but to prosecute by indictment. If the Act of 1866, together with the Public Health Act, imposed an intolerable burden on the Local Board, their remedy was to go to Parliament for relief. Shortly his argument was that the person who suffered the sewage to flow into the Thames from the three sewers in question was the local authority in whom the drains were vested. They had the right under the Public Health Act to stop up or divert the sewers.

Justice WILLS pointed out that the right was only conditional on providing equally convenient sewers; and before a man could be held guilty for not closing a sewer, it must be shown that it was possible for him to comply with that condition. It seemed to him the special verdict was hopelessly deficient in this respect.

Mr. CRUMP contended that the onus lay on the defendants to show they could not stop up the drains over which persons claimed prescriptive rights. They suffered this sewage to pass, because they did not prevent it. The question of penalty, of course, would be in the discretion of the Court.

Justice FIELD said this was a case of great public importance; and if he had entertained any doubt about it, he should have reserved judgment, because it seemed to him that, if the opinion of the Court was (as it was) that the indictment failed, there would be very great difficulty on the part of the Conservators in performing one of their chief duties—that of keeping the Thames free from pollution. But he entertained no doubt whatever about the case, which appeared to him to be entirely covered by the authorities which had been alluded to by Sir H. James. Having gone through the sections of the Act of 1866, and also of the Public Health Act of 1875, to see what were the duties and powers of the Conservators on the one hand, and of the Local Board on the other, he referred to the special verdict, which found in terms that no sewage matter had been passed into the Thames by the Local Board, or with their consent; and the only question therefore was whether they had suffered it to pass. He thought it was clear that a prescriptive right to pass sewage, such as was

claimed by certain house-owners in Staines could be acquired; and it was stated that such owners did drain into the sewers communicating to the Thames in the exercise of their prescriptive right. Was that an averment that the defendants had suffered sewage to pass? It could not be said that they "suffered" that which others had a right to do. In order to "suffer" it, they must have the power to stop it; and it seemed to be decided by the two cases cited that they had no such right. If there had been no authority, he should have said that the verdict must be "not guilty," because there were no sufficient averments in the verdict to found a judgment of "guilty;" but the cases cited put the matter beyond doubt. There must be judgment for the defendants.

Justice WILLS entirely concurred in the decision.

Mr. ATKINSON applied for costs.

Justice FIELD said the Court had no power to give costs in such a case

Miscellaneous News.

THE CHARGES IN CONNECTION WITH THE HALIFAX GAS-WORKS.

The *Halifax Courier*, referring to the above matter last Saturday, said: "The Sub-Committee appointed to deal with the matter of the gas coal contracts met on Thursday. We understand that they have obtained evidence to satisfy them that the cannel coal which has been supplied by Mr. Wrigley is not hand-picked as agreed for by contract; and in consequence of this the Committee have decided to cancel the contract with Mr. Wrigley, and purchase the quantity required elsewhere. One of two things will no doubt follow—either Mr. Wrigley will sue the Corporation for breach of contract, or the Corporation will have to take the initiative and seek damages from Mr. Wrigley. The contract was entered into about May last, and was for 6000 tons of coal. A portion of that has, of course, been delivered."

In connection with the same matter, the *Ashton-under-Lyne Reporter* (which, our local correspondent says, probably represents the view taken by Mr. Wrigley) stated as follows:—"The Halifax gas troubles are now coming to a head, so far as the coal contracts are concerned. It will be remembered that the Mayor charged one of the contractors with delivering cannel inferior to that contracted for. As this comment upon a running Corporation contract was uttered in the Council chamber, it has been ruled by Counsel that the Mayor was within his rights in criticizing any contract from his seat in the Council, and that in any action-at-law he would be justified in pleading privilege. Being anxious to challenge the absolute faithfulness of the cannel deliveries, in point of quality and in every other respect, Mr. E. G. Wrigley and his Solicitor (Mr. W. Cobbett) had an interview with the Mayor, and it was arranged that the Halifax Corporation should enter an action against Mr. Wrigley to recover a fixed sum per ton for alleged inferior quality. This the Corporation have now decided to do; and Mr. Wrigley will defend the action. The public will now, of a certainty, shortly be able to form correct opinions from proper and reliable evidence. The difference between them is not that of substituting one cannel for another, but it is whether the cannel delivered was hand-picked or screened-picked cannel. Mr. Alderman Riley has declined to prosecute Mr. T. K. Fox unless he will charge him specifically with receiving commissions on coal or other contracts, or in some specific way will define what is meant by being guilty of 'malpractices,' which may mean anything or nothing."

SALFORD CORPORATION GAS SUPPLY.

THE HUNTER CASE.—THE CORRESPONDENCE WITH MR. ELLIS LEVER.—THE PROPOSED AMALGAMATION OF MANCHESTER AND SALFORD.

At the Meeting of the Salford Town Council last Wednesday—the Mayor (Mr. Alderman A. L. Dickens) in the chair—the above-named matters were under consideration.

The Mayor said that at the last meeting of the Consultative Committee, it was thought desirable that some statement should be made, in consequence of certain observations passed in the Council Chamber some months ago relative to a letter which had been received from Mr. Hunter's Solicitor, offering the Corporation the sum of £20,000 in connection with matters which formed the basis of the proceedings in which they were then engaged. The statements so made were enlarged upon outside the Town Hall. Remarks were made in the newspapers; and it had been said that Salford had lost £20,000 because of the non-acceptance of the offer which had been made. It was thought, therefore, that, in the interests of the borough, the matter should be set at rest; and with that object a case was submitted to Sir Charles Russell. When in London recently, he (the Mayor) called upon Sir Charles, who had since, acting in concert with Mr. Poland, presented the following written opinion on the matter:—" (1) We are clearly of opinion that the representatives of the Corporation would not, under the circumstances stated, have been justified in entering into any agreement for the acceptance of a sum of money which would have been carried by implication the condition that the prosecution should practically be waived by the appearance of representatives of the Corporation as witnesses on behalf of the prisoner. (2) We are clearly of opinion that the Corporation could not have acted in any other way with reference to the offer made. Before the defendant pleaded guilty, the representatives of the Corporation would have acted illegally in entering into any such agreement as that proposed; and all the parties who entered into such an agreement would have rendered themselves liable to be charged with a criminal offence. After the defendant had pleaded guilty, and before sentence, we are equally clear that the representatives of the Corporation could not have accepted the sum offered in the letter of April 12, on the condition that the Mayor and possibly one or more members of the Corporation should enter the witness-box and do what was possible on behalf of the prisoner when brought up for sentence. The only straightforward and open course was for the defendant to pay into the Chancery Division of the High Court any sum he thought fit; being the amount of the commissions he had improperly and illegally received, without any condition being attached to such payment so far as the criminal proceedings were concerned; leaving the Judge, when the whole facts were stated to him, to take into consideration, in the defendant's favour, the amount of money he had paid by way of restitution. We may add that we warned the Town Clerk that neither he nor the representatives of the Corporation should enter into any bargain such as that proposed connected with the criminal proceedings." He added that he thought comment upon this opinion was unnecessary.

The subject of the correspondence which has taken place between the Mayor and Mr. Ellis Lever, relating chiefly to the constitution of the Sub-Committee to be appointed to receive certain information which this gentleman has promised to give on certain conditions, was then introduced. Mr. Lever, it will be remembered, strongly objected to the Sub-Committee nominated by the Council at the last meeting (see *ante*, p. 645). As Mr. Lever persisted in his objection, the Mayor ultimately wrote to him, asking him to name the members of the Council to

whom he was willing to give certain information referred to in his letter of Sept. 26. To this request Mr. Lever replied by wire, on Oct. 25, stating that he had been engaged at Leeds for three days investigating the coal supplies of the Corporation, and that on his return he would reply to the Mayor's last letter. On the 27th he wrote: "In reply to your letter of the 22nd inst., I beg to say that my intention, as expressed in my letter to the press of the 26th of September, was that my nominees—who would be members of the Council—should elect the third member of the Sub-Committee. With regard to your request that I should give you the names of my nominees, I think you will agree that if the Council do not see fit to accept my nomination, the gentlemen named will be placed in a very anomalous and unpleasant position. Unless the Council lacks faith in some of its members, there can be no reason why an open resolution should not be passed, leaving the names to be supplied afterwards." Another portion of the correspondence related to a statement made by the Mayor at the last meeting of the Council—that Mr. Lever had had many opportunities of communicating to the Council any information he possessed, and had not availed himself of them. This statement Mr. Lever denied; and he gave the names of certain members of the Council to whom he had imparted certain information in his possession, but these members had neglected to make use of it. On the suggestion of the Mayor, the members of the Corporation referred to explained the circumstances under which they had obtained the information from Mr. Lever, and endeavoured to show that it was communicated in such a form that no use could be made of it.

Mr. F. S. PHILLIPS next moved the following resolution:—"That the resolution of the Council passed on the 3rd of October in reference to the frauds alleged by Mr. Ellis Lever to be now going on in the supply of coal to the gas-works be rescinded, so far as it relates to the appointment of a Committee, and that, in lieu thereof, this Council consents to Mr. Lever's proposal that he shall nominate two members of the Council, who, being so nominated, shall themselves appoint a third, to whom he will disclose evidence of such frauds; and that the said members so selected shall be appointed to form themselves into a Sub-Committee, to receive such evidence, and to report thereon to the Council." He remarked that the motion was merely the outcome of communications with Mr. Lever. This gentleman had declined to accept the Committee which had been appointed by the Council; and he (Mr. Phillips) took the liberty of suggesting that Mr. Oliver Heywood should be asked to nominate a Committee. This suggestion was not agreed to by Mr. Lever; and as it was desirable that the matter should be brought to an issue, he (Mr. Phillips) proposed his resolution.

Mr. H. ROPER seconded the motion.

The Mayor said the Committee suggested in the resolution was one similar to that which Mr. Lever himself had asked the Council to grant him; and it certainly was one which would be judge and jury. However, when the Committee was appointed, he would take great care that he was present himself, in virtue of his office as Mayor, as Chairman.

Mr. SNAPE said that as Mr. Lever seemed to think that he could only communicate his information to gentlemen of his own selection, he was prepared to give way, although he thought Mr. Lever was altogether wanting in fairness. He would suggest that a shorthand writer should be engaged to be present during the proceedings.

Mr. G. W. GADD expressed his full conviction that they would find Mr. Lever would back out of it.

Alderman WALMSLEY asked what would be the effect of adopting the resolution.

The Mayor said Mr. Lever would be communicated with, and asked to substantiate the statements he had made in his letter to the papers on the 26th of September.

Mr. RYECROFT said he thought they had been wasting too much time in discussing the matter. If Mr. Lever had any information to communicate to the Corporation which would be of any value, he thought they ought not to hesitate in accepting it in the way Mr. Lever proposed to give it.

Mr. H. LORD said that, as Chairman of the Gas Committee, he thought it was to be regretted that Mr. Lever had not accepted the Committee nominated by the Council; but at the same time he cordially invited Mr. Lever, if he had any information to give, to let them have it, so that they might put an end to the rumours that were going about.

The resolution was then carried unanimously.

Alderman WALMSLEY had placed the following motion on the paper:—"That a Committee be appointed, consisting of 16 members of the Council, to take into consideration the report recently issued by the Association for dealing with the question of the amalgamation of Manchester and Salford, and to report thereon; also that such Committee be authorized to call in such professional assistance as it may deem necessary." He said that, as this was the last meeting of the Council for the municipal year, the powers of the Committee he wished to appoint would expire that night; and therefore he would postpone his motion till the next meeting of the Council. At the same time he remarked that the subject would be thoroughly investigated before a decision was come to on the proposals of the Association.

STARTLING REVELATIONS BY A FORMER COUNCILLOR.

At one of the meetings held in Salford prior to the municipal elections, some extraordinary revelations in connection with the circumstances which have during the past twelve months attracted so much attention to the gas undertaking of the Corporation, were made by a candidate (Mr. Ward), who had formerly been a member of the municipal body, and sought re-election in place of a retiring councillor. In view of the matter now specially engaging the attention of the Council, as shown by the proceedings reported above, it may be of interest to reproduce the remarks of the gentleman in question.

Mr. Ward, in the course of his address, said that his audience would no doubt have seen that Mr. Ellis Lever had been writing to the newspapers, and posing as a man interested in the welfare of Salford. He (Mr. Ward) had been asked many times why the old Gas Committee, of which he was formerly a member, did not consider Mr. Lever's tenders in 1886. They were not considered in 1883, and perhaps not in 1880. He was quite satisfied that the name of Mr. Lever should be struck off the list of those who had sent in tenders, for this reason: Mr. Lever offered them Wigan 4 feet Golborne coal at 9s. 6d. per ton, and the Committee did not look at any tender at such a price; the highest they considered being 8s. 5d. to 9s. Had his offers been at 8s. 6d. per ton, they would have been considered with the rest of the tenders. After the *Hunter v. Lever* trial, a letter appeared in the newspapers from Mr. S. Norbury Williams, asking for subscriptions to recoup Mr. Lever for the expense he had been put to in defending himself. Hunter was compelled by the Gas Committee to prosecute Lever. When Hunter sent in his resignation as Gas Manager, he (Mr. Ward) moved in Committee that it be not accepted, but that he be dismissed, and that an Investigation Committee be appointed. These resolutions were passed; but they were stolen from him in the Council. Subsequently he wrote to Mr. Williams, asking if he was able to give any information as to the success of his appeal for funds for Mr. Lever.

Mr. Williams sent for him, and said, "The reason I did not prosecute that appeal was because I received a letter from a certain gentleman who knows what's what." Mr. Williams eventually gave him a copy of the letter. [Mr. Ward here read a letter from Mr. C. W. Provis, auctioneer, Manchester, dated Oct. 6, 1887, making some libellous charges against Mr. Lever.] He (Mr. Ward) had not only done his best, while a member of the Council, to prevent corporate officials doing wrong, especially Mr. Hunter, but he had set his face decidedly against Mr. Ellis Lever. He happened to know how often Lever had been at the Bloom Street offices with the former Gas Manager; and he happened to know, from conversation with Mr. Hunter, that Mr. Lever had made certain offers to him with regard to the sale of coal. But he would afterwards have treated Hunter as he did Matthew Hiltor, formerly a member of the Manchester Corporation Gas Committee. On one of Mr. Lever's journeys to Bloom Street, he met Mrs. Hunter—that was in 1886—and said to her: "I cannot prevail upon your husband to take my house at Colwyn Bay. Will you try?" She said: "Oh, I have nothing to do with it." He had seen a letter from Miss Lever to the Hunters regarding the house. What was all that for? Was it not an effort to get hold of the Corporation official? He made those statements on the information of Hunter; and he could produce letters in proof thereof, if asked to do so. They would remember that, at the first hearing of the Hunter trial in London, an adjournment was granted in order that an umpire might be appointed to decide what amount Hunter should refund to the Corporation. One was nominated by Hunter's Solicitors; but he was rejected by the Corporation. There would have been some startling information had Hunter put on paper what he knew; but they would not give him an opportunity. This was kept back by the late Town Clerk (Mr. Graves). The Consultative Committee refused to accept £22,000, which was offered by Hunter. The Town Clerk would not allow it to be accepted, and £28,000 was asked. This amount was not there; but the £22,000 was in the hands of Hunter's Solicitors. He (Mr. Ward) said at the time it was refused, "It is your last chance." He contended that it would cost the ratepayers £5000 above any money they would get from Hunter, through the inefficient, slow, and bungling way in which the prosecution had been conducted. The late Town Clerk, more than anyone else, was to blame. Mr. Graves owed £100 to Hunter; and when it came to a close crisis in the prosecution, the amount had to be repaid. Where did he get it from? Why, he went to two Aldermen, and they found it for him, and the money was paid. They had not got at the whole truth yet. In 1880, when the contracts for coal and cannel were let, Alderman Keeney and Mr. Mandley, who had done so much to cry down Hunter, both coincided in the resolution passed that three members of the Committee, with the Gas Engineer, be appointed to select the contractors. This was placing in Hunter's hands a way to "do" them. They had no such system in 1886; a full Committee of 12 members out of the 16 were present when the contracts were accepted. He, therefore, blamed Messrs. Keeney and Mandley for the cause of the whole of the gas scandals for which Salford was suffering. He concurred in the resolution for dissolving the Gas Committee on the distinct understanding that all the new members, of which he was one, should be re-elected on the new Committee. As he was not re-elected, he felt that his character was gone. He entered the Council with a character, and according to some people he was not to be trusted now.

In the course of his reply to questions, the candidate said, in response to an inquiry as to how, if the Committee accepted the coal and cannel tenders, Hunter could put 3d. or 6d. per ton on the coal, that the tenders offered the last time the coal contracts were let consisted of 48 different colliery proprietors and agents, which embraced 72 different classes of coal and cannel. The tenders were presented to the Committee in sealed envelopes; they were opened and initialed by the Chairman, and then handed over to the Gas Engineer to be tabulated. Copies were subsequently sent to each member of the Committee; and they were afterwards accepted.

MR. ELLIS LEVER AND THE LEEDS GAS COAL CONTRACTS.

The Sub-Committee appointed by the Gas Committee of the Leeds Corporation to deal with the charges made by Mr. Ellis Lever in connection with the gas coal contracts, to which several references have been made in our columns, were busily engaged last week in investigating the statements made by him in the report he presented on the results of his examination of the coal at present being supplied to the Corporation. It will be remembered that the coal tested by Mr. Lever on its way to the works was, as he asserted, deficient to the extent of from 6 to 15 per cent. in quality, as compared with that submitted to the Corporation when the tenders were accepted; and that even in some cases it was found to be inferior by from 20 to 30 per cent. He also condemned the existing system of checking and weighing the coal. The Sub-Committee had a meeting last Tuesday, under the presidency of Mr. P. Gilstou, the Chairman of the Gas Committee; the Town Clerk (Sir G. W. Morrison) and the Secretary of the Gas Department (Mr. J. Lupton) being in attendance. Mr. Lever was not present. The Chairman and Managing Director of one, and the Trustees and Manager of another colliery Company who supply coal and cannel to the Corporation were called in to explain away the allegations of Mr. Lever; and they stated that men were specially appointed at the pits to see that coal of the proper quality was sent off, and if any inferior coal had found its way into that supplied to the Gas Department, it must have occurred through the carelessness of these men. They utterly denied, however, the possibility of so large a percentage of inferior coal being conveyed to Leeds for the purpose of gas making. On the following day, the Sub-Committee, accompanied by the representatives of the collieries concerned, proceeded to the siding of the London and North-Western Railway Company at New Wortley, where two trucks of coal which had been examined by Mr. Lever were standing. A quantity of cannel coal was shovelled from each truck, and examined by the representatives of the two collieries, who both declared that this particular coal was quite up to the sample from which they had sold coal to the Corporation. One of these representatives was so confident that he offered, if the coal did not yield a result equal to sample, to give 100 guineas. Afterwards the Committee proceeded to the Meadow Lane works, where samples of coal which had been laid aside by Mr. Lever in safe keeping for future examination were selected. One sack from each sample of the cannel taken from the trucks by Mr. Lever was placed upon the ground and examined, and in both cases the coal contractors declared that there was no "hub" (which Mr. Lever says is useless for gas manufacturing purposes) present in the material. The Committee then determined that a preliminary trial should be made, by the coal tester to the Corporation, of a specimen of this "hub" from one of the collieries. The test was accordingly made straightway; and it gave a result of 10,700 cubic feet of gas per ton of coal, with an illuminating power of 26.73 candles, tested by the standard flat-flame burner. On the completion of this trial, another experiment was made from a sample of the "hub" from the other colliery referred to by Mr. Lever; and this showed returns equal to a yield of 11,900 cubic feet of gas per ton of coal, with an illuminating power of 25.53 candles. The Committee then determined that the slack, the "hub," and the pure cannel, selected by

Mr. Lever, together with samples from the bulk of coal taken from each of the trucks whence the coal tested was taken, should be placed in the hands of Mr. Thomas Fairley, F.C.S., the Borough Analyst, to examine and report upon. Later in the day, the Town Clerk wrote to Mr. Lever informing him of this arrangement, and also of the results of the test made at Meadow Lane. He further intimated that the Sub-Committee was anxious to afford him every facility for making a further examination of the coal in the two trucks in question, and that the material would be placed at his disposal, in order that he might submit it to any analyst of standing whom he might choose to name. On Thursday, Mr. Lever sent to the Leeds papers the following telegram:—"I wish it to be known that I have not been invited to meet the Committee appointed last Friday [Oct. 26] and the representatives of the collieries whose material I have examined and condemned as containing foreign matter contrary to the stipulations of their contracts. I am prepared to vindicate my statements that the cannel contains 'hub,' slack, and pyrites. I will also undertake to bring Mr. James Paterson, F.G.S., to examine the cannel, 'hub,' and slack, to report upon it, and make independent commercial analyses. How comes it that my detection of inferior material in waggon 65 corroborated the analysis made on the 6th of October, when the cannel showed 25 per cent. of inferiority?" In a later telegram, Mr. Lever stated that he had wired to the Mayor of Leeds as follows:—"Will you make it known to the Press to-night that I have not been asked to meet the Committee of Investigation or to interrogate the contractors, neither was I present yesterday when the alleged testings took place. I do not believe in such investigations, nor will the public." In reference to the first telegram, the *Leeds Mercury* last Friday was authorized to state that, for the purpose of testing the coal contained in the trucks inspected by Mr. Lever along with the Sub-Committee, four sackfuls were taken. In each instance one sackful was used by the Sub-Committee for the purpose of their own test; the other sacks being placed under lock and key, and put into the possession of Mr. Fairley, for the purpose of analysis. The results will be published in due course. The Sub-Committee say they are quite satisfied with the result of the ordinary test made at the works to ascertain the illuminating value of the coal selected by Mr. Lever. Moreover, they will not offer any objection to that gentleman, or any other person concerned, having independent analyses made of the coal now in the possession of Mr. Fairley. They were not aware that Mr. Lever had expressed any desire to attend the meetings at which the representatives of the collieries concerned were present; but when the analysis is officially made by Mr. Fairley, every opportunity will be given to Mr. Lever, and any analyst he may wish to employ, to check the tests—the same facility being afforded to the colliery contractors concerned in the matter.

PARTICK, HILLHEAD, AND MARYHILL GAS COMPANY.

An Extraordinary General Meeting of the above Company will be held next Thursday, for the purpose of considering resolutions authorizing the Directors to enter into an agreement with the Corporation of Glasgow for the sale to them of the whole of the Company's undertaking and assets, at the net price, over and above the Company's liabilities, of £122,370; and sanctioning the payment to the holders of the 5½ per cent. preference shares of the amount of their shares and 10 per cent. premium, and to the holders of the ordinary shares of the amount of their shares, less 10 per cent. discount. With the notice convening the meeting, the Directors issued a circular placing before the shareholders the circumstances which have led them to submit the special resolutions referred to therein. In it they explained that the Corporation of Glasgow are desirous of obtaining an extension of the boundaries of the city, so as to include a part, if not the whole of the district supplied by the Company. The Directors, considering that such extensions, if carried out, would be prejudicial to the interests of the Company, appeared before the Boundary Commission, and pointed out in what ways the scheme would injuriously affect the Company; dwelling specially on the possible loss of the lighting of the streets and common stairs, and the eventual sacrifice of the supply of gas to the dwellings approached therefrom. The Commissioners promised that, if they reported in favour of annexation, they would specify that any claim the Company might have for terms, either as to future rights or compensation or otherwise, would have to be dealt with if their recommendation were carried into effect. After this deliverance had been pronounced, the Directors were approached in an informal manner by influential members of the Town Council of Glasgow, who indicated that, if satisfactory terms could be adjusted, the Corporation would be prepared to purchase the Company's undertaking. The Directors agreed to entertain the proposals made; and various conferences were held between representatives on both sides, with the result, as our readers are aware, that the Council have agreed, and now offer, conditionally upon a Bill being carried before Aug. 15, 1889, for the annexation to the city of the district supplied by the Company, to purchase the Company's undertaking on the terms already stated. It is a part of the proposed arrangement that, if the Annexation Bill is passed by the above date, a Bill is to be introduced into Parliament in the session of 1890, empowering the Corporation and the Company to carry out the arrangement; and provision is made under which the Company's business will be carried on as usual until the transfer is completed—the preference shareholders receiving in the meantime their full dividend, but the dividend to the ordinary shareholders being limited to 4 per cent. The Directors say that, in judging of the terms offered, the shareholders should keep in view (1) that, while it is no doubt uncertain whether an extension of the boundaries of Glasgow will take place or not, the fact of a Commission having reported in favour of extension cannot be left out of account; and (2) that it is doubtful how far it would be found possible to insert in any Annexation Bill clauses adequate to protect the Company's interests. The Directors are of opinion that the terms offered should be accepted. Pending the acquisition of the works by the Corporation, the Directors are putting them into a condition to adequately meet the calls made upon them. They have just set to work another new telescopic gasholder, 100 feet by 50 feet, bringing up their storage capacity to 20 hours' consumption. All the heavy ironwork of a gasholder, 100 feet by 40 feet, which stood in the way of improvements at the Tradeston Gas-Works has been removed, adapted, and entirely replated and resheeted satisfactorily, to suit the requirements of the Company, by the Airdrie Iron Company. This, with 1800 yards of railway laid down through the works, a large condenser and washer-scrubber, increasing the height of the old scrubbers, and doubling the storage capacity for tar and liquor, with sundry other improvements, has been found necessary to satisfy the increasing demand for gas. These extensions have been carried out under the supervision of the Company's Engineer and Manager (Mr. Levi Monk).

KETTERING WATER SUPPLY.—At the meeting of the Kettering Water Company last Thursday it was resolved to carry out the scheme for obtaining a fresh supply of water to which reference was made last week (p. 771). It is estimated that for the completion of the work an outlay of £32,000 will be required. The Local Board, it will be remembered, are now considering the advisability of purchasing the undertaking.

WENHAM COMPANY, LIMITED.

The Ordinary General Meeting of this Company was held last Tuesday, at Winchester House, Old Broad Street—Mr. D. A. TRAILL CHRISTIE in the chair.

The notice convening the meeting having been read, the Directors' report was presented.

The CHAIRMAN, in moving the adoption of the report, remarked that although the Company only dated from May last, the accounts had been made up as representing a whole year, in order that the business might be a continuous one. The charges were substantially less; and in the current year they would be still further reduced. The manufacturing gross profit account showed a balance of £28,561, or a falling off of £9800, as compared with the previous year. Of this amount, however, at least £1500 was owing to the rise in the price of metal and the increased discounts allowed to the trade; but the main disappointment had been in the Continental department, especially France. Owing to certain ill-advised transactions, they had found it necessary to reorganize their business in that country. They had terminated the engagement of their Agent, and had selected as his successor one who they hoped would prove to be "the right man in the right place." As yet it was too early to speak of results; but the Directors had already very favourable impressions of the prospect there seemed to be of the new Manager inaugurating a more successful *régime*, although for some time he would have to contend with an inheritance for which he was in no way responsible. Both in France and in Germany there had been local difficulties and oppositions to contend against; and these had certainly led, in the year under review, to a diminution in the profits, irrespective of other special causes. In the case of Germany, where the Company were most energetically and ably represented, the falling off in the volume of business had been due, as mentioned in the report, partly to the competition of other systems of lighting supported by local interest, and partly to the adverse influence on business generally of the preoccupation and anxiety more or less prevailing during the late changes in that country. Both of these causes had operated in the way of producing a certain suspense; and between the two, and the necessity they entailed for increased expenditure in trying to push business in face of them, and the tendency of purchasers to prefer the less expensive forms of lamp, there was enough to account for the less favourable result the Directors had unfortunately experienced. If, while still reckoning on the German branch for a very solid contribution to the profits, it was difficult to speak with the certainty one could wish on all points of the outlook of the two Continental branches of the business, it was satisfactory to see, on the other hand, the growing popularity of the Company's system of lighting at home, as indicated by the substantial increase—3000—in the number of lamps sold as compared with those disposed of in the previous year; and the prospects were encouraging. The net profit had been £13,175, out of which they had paid an interim dividend of 5 per cent. They now proposed to apply £2000 in reduction of patents and business purchase account, and to recommend a dividend of 3d. a share; making the total distribution for the year 6½ per cent. on the capital of the Company.

Mr. TYZER seconded the motion, which, after a long discussion, was carried unanimously, and the dividend recommended declared.

The other business having been disposed of, including a resolution reducing the number of Directors to six, thanks were accorded to the Board, and the proceedings closed.

DINSMORE GAS COMPANY, LIMITED.

An Extraordinary General Meeting of this Company was held in Liverpool last Wednesday—Mr. M. GURRIN in the chair.

The notice convening the meeting having been read,

The CHAIRMAN, in presenting the Directors' report, said the Company was formed about twelve months ago for the purpose of acquiring patents taken out by Mr. Dinsmore for making coal gas.* After carrying on experiments at the works in Emlyn Street, arrangements were made for some trials on a manufacturing scale at the Hoylake as well as at the Widnes Gas-Works. The ordinary production of gas from Lancashire coal was about 10,500 cubic feet per ton; and the illuminating power about 16 candles. Consequently, cannel had to be used to raise it. But cannel was expensive; and the price of gas was consequently increased. Experiment had shown that the hydrocarbons contained in the tar produced in the manufacture of gas could be converted into gas during the process; and the value of the gas be much more than the value of the tar residual. This the Dinsmore process accomplished; and preliminary experiments showed that from a ton of Lancashire coal 12,000 cubic feet of gas could be generated, ranging from 22 to 23 candles in illuminating power. At Hoylake, from 11,300 to 12,650 cubic feet were produced per ton, and the illuminating power was 20 to 21 candles; but not more than half the tar was used. At Widnes, from Yorkshire coal, 13,000 cubic feet of gas were produced; and the illuminating power was from 20 to 24 candles—using not more than one-third or one-half of the tar. With Yorkshire coal by the ordinary process at Llandudno only 10,748 cubic feet of gas were produced; and the illuminating power was 18 candles. The Directors were fully convinced that satisfactory commercial results could be obtained by the process, and that in some towns it would effect a saving of many thousands of pounds annually. Broadly speaking, the nature of the invention was the addition of a duct or secondary retort placed above the ordinary retorts in a bench of two, four, or six, as might be found most useful. Into this duct was conveyed the gas from the ordinary retorts, and at the same time there was also conveyed a small stream of tar, which, falling upon the highly-heated surface, was converted into gas, leaving a solid carbon residual. This conversion of the tar into gas and mixing with the ordinary gas in a heated chamber was the Dinsmore process. The idea was not a new one; but it had never been satisfactorily carried out.

Mr. WATSON said he had heard it freely stated on "Change that the Hoylake tests proved a failure.

The CHAIRMAN said this was scarcely accurate, though, owing to defective furnaces, they had to burn more fuel than they should have done. At Widnes no more fuel was used than usual. He moved—"That the Directors be authorized to pay Mr. Dinsmore, out of the funds of the Company, such sum or sums of money, or to give him such other consideration as the Directors may think fit, in exchange for the acquisition by the Company of any present or future inventions or discoveries by Mr. Dinsmore, or the interest of Mr. Dinsmore therein, which the Directors may in their discretion think it desirable to acquire; and to enter into any agreement or agreements from time to time for such purpose, notwithstanding the agreement made between Mr. Dinsmore and others of the one part, and the Company of the other part, dated the 17th day of November, 1887." He remarked that this resolution would enable the Company to acquire any other of Mr. Dinsmore's inventions they might deem desirable.

Mr. M'CONKEY seconded the motion, and it was carried.

A vote of thanks to the Chairman terminated the proceedings.

SOUTHWARK AND VAUXHALL WATER COMPANY.

A Special General Meeting of the shareholders of this Company was held last Tuesday, at the Offices, Sumner Street, Southwark—Alderman Sir H. E. KNIGHT in the chair—for the purpose of sanctioning the creation of the debenture stock authorized by the Company's Act of 1886.

The SECRETARY (Mr. A. Jelley) having read the notice convening the meeting,

The CHAIRMAN said the shareholders were aware that when they obtained the Act of 1886 for carrying out additional works, the House of Commons required that they should raise the extra capital by debenture stock, which was to be offered to the public by tender or sold by auction. The Directors proposed to offer the stock to the public by tender; but they had given the shareholders special notice, thinking that they might like a preference given to them, though the Board were compelled, under the Act, to take the highest tender. The time had arrived when they found it was necessary to issue a portion of the capital; but this could not be done without the shareholders' approval. The Directors had, therefore, asked them to attend that meeting to give the Board authority to raise the £300,000 sanctioned by the Act, although they purposed issuing only £100,000. The new works authorized by the Act were in a very forward state of progress. The Directors had, according to the best of their business knowledge and ability, financed the operations so far, till the time had arrived when they found that new capital must be raised in the interests of the Company. He concluded by moving—"That the sum of £300,000, being the sum authorized by the Southwark and Vauxhall Water Act, 1886, to be raised by the creation and issue of debenture stock, be, in exercise of the powers conferred by the said Act, raised by the Directors by the creation and issue of debenture stock to that amount, to be called 4 per cent. debenture stock, on such terms and conditions and at such time and in such manner consistent with the said Act, as the Directors may from time to time deem expedient."

A SHAREHOLDER asked what would be the minimum price.

The CHAIRMAN replied that on the last occasion they issued debenture stock, it went at £109 10s. In the case of the present issue, they had not decided upon the minimum; and it was not usual to do so until the stock was offered. The minimum would be that which was most consistent with the interests of the Company; but it was a question which the Directors would have to carefully consider. In reply to a further question, he said that the capital was required for a new main from Hampton running through the whole of their district to Nunhead. A large portion of the main was laid. It was a 40-inch main, and would cost the Company possibly £80,000, or £90,000. They had some very large filtration works also to carry out at Hampton. A new engine-house would have to be built, and a new station at Wandsworth; and there were reservoirs, engine-houses, and other works to be constructed.

Alderman D. H. STONE seconded the motion, which was carried.

The CHAIRMAN, replying to an inquiry as to the position of the well at Sireatham, stated that they had now reached to a very great depth. The well was an interesting work to geologists, and to the public generally; but it must not be forgotten that the Company were only interested in it as a Water Company. They had no power or right to spend the money of the Company in other ways than in searching for water. In the course of the previous week, they went through some hard rocks; but they were now in a more yielding substance, samples of which had been submitted to Professor Whitaker. They had done everything consistent with their duty as water caterers so far, and nothing beyond it. If the Professor advised them that there was a fair probability of water being found at a lower depth, they might spend more money in going deeper to discover it; but if his report was against that probability, they would not go down farther. If, however, in the latter case any scientific gentlemen were interested, and would like to continue the boring, they could probably arrange with them to use the Company's plant. With regard to the well itself, it was a success, as they had found, in the upper greensand, a large supply of beautiful water, which they would utilize; and it would afford them some millions of gallons of water per day for use in the district. The money which had been spent had, therefore, been wisely expended, as by that means they had procured a good auxiliary supply to that which they drew from the River Thames. Then they could also fall back on the other springs. He conscientiously felt that they had done their duty in searching as far as they could. If they could have tapped a boundless supply in the lower greensand, it might have saved them laying the main from Hampton, which would cost them between £80,000 and £90,000; but they were entirely dependent upon the reports of learned and scientific men who were supposed to fully understand these matters. All the strata which those gentlemen told them they would go through they had gone through. The depth was now 1161 feet. Finding hard rocks, they had felt inclined to stop; but he did not readily "cave in," and against the advice of some of his friends, he quietly told the Engineer to "plunge away." This had been done to the depth of 12 feet. He thought it might be a boulder that had fallen forward on the top of the soft material. They would do everything that ought to be done; but they would not spend a shilling of the shareholders' money except in searching for water.

A vote of thanks was accorded to the Chairman; and the proceedings terminated.

THE PUBLIC LIGHTING OF PADDINGTON.—According to the report of the Paddington Vestry for the year ending March 25 last, there were in use on that day 1959 lamps, each estimated to consume 4·6 cubic feet of gas per hour. The actual consumption per hour for the year was 5252 cubic feet; each lamp burning for 3790½ hours, or an average of 10·63 hours per night. The estimated consumption per lamp per annum, at 4·6 cubic feet per hour, is 17,897 cubic feet; but the actual consumption was 17,633 cubic feet. There were at the date of the report 97 meters attached to the lamps. The price was reduced on Jan. 1 from 2s. 5d. to 2s. 2d. per 1000 feet.

SHOREHAM AND DISTRICT WATER COMPANY.—The thirty-seventh half yearly general meeting of this Company was held last Saturday week—Mr. T. Fuller, M.D. (the Chairman of the Company), presiding. The only business before the meeting was the consideration of the Directors' report for the half year ending June 30 last, and this was unanimously adopted. The amount available for distribution was not so large as at the corresponding period of last year; but the Directors recommended the following appropriation of the balance:—A dividend at the rate of 5 per cent. per annum (less income-tax) on the preference shares, £195; a dividend of 5 per cent. for the half year (free of tax) on the ordinary shares, £375; and to carry forward to the next account £145 19s.—total, £715 19s. The statement of accounts accompanying the report showed that the receipts during the past half year (including a balance brought forward from last account of £669 11s. 5d.) were £1858 3s.; the rates and meter-rents constituting £1165 3s. 10d. of this sum. The expenditure amounted to £1142 4s.; leaving the balance stated above. Resolutions were carried declaring dividends in accordance with the recommendations of the Directors.

* An abstract of one of Mr. Dinsmore's specifications was given in the JOURNAL last week (p. 784).

EDINBURGH AND LEITH GAS COMMISSION.

At the Meeting of the Edinburgh and Leith Gas Commission on Monday last week, a communication was submitted from the Manager of the Leith works (Mr. Linton), forwarding a request by the Leith workmen to be put on the same footing as the Edinburgh men in regard to wages and time. Bailie Archibald pointed out that the demand, if conceded, would involve a considerable increase of expenditure; but he moved that the retort men should be placed in the position they were in up to 1896, and that the cases of the other men should be left in the hands of the Manager. Bailie Garland seconded the motion. Bailie Roberts said the discussion at the last meeting (see *ante*, p. 769) had set the men on edge; and they thought they could come up to the Commission with every petty matter. The question should be left in the hands of the Manager. Bailie Cranston considered that the Leith men should be put on the same terms as those in Edinburgh. A conversational discussion ensued, in which the desirableness of revising the wages of both the Edinburgh and Leith men was suggested. Ultimately the whole question of wages in both works was remitted to the Works Committee. Provost Aitken said that he was not present at the former meeting when Mr. Jack was appointed Clerk; but he understood he was appointed provisionally for a period of three months. The time had now come when a permanent appointment had to be made; and he had great pleasure in moving that Mr. Jack be appointed Clerk of the Commissioners. Treasurer Boyd seconded the proposition. Bailie Archibald said he would suggest that a remit be made to the Finance Committee to report upon the duties, salary, and office of the Clerk; and that in the meantime Mr. Jack be appointed provisionally. It was eventually resolved to appoint Mr. Jack during pleasure; and the other matters were remitted to the Finance Committee. The Chairman (Lord Provost Clark) intimated the appointment to Mr. Jack, who declared that he would faithfully discharge the duties imposed upon him. Bailie Turnbull suggested that a remit should be made to a Committee to arrange for members of the Commission visiting the works periodically, in accordance with the practice of the Directors of the Companies in the past. The suggestion was adopted. On the motion of Bailie Archibald, it was agreed to have monthly returns of the quantity of gas manufactured at each works, the amount consumed, and the income and expenditure for the month. At the close of the proceedings, Lord Provost Clark said that was the last time he should have the pleasure of presiding, and he could only say he hoped they would have a very successful year, and that all the unfavourable prognostications as to the Trust would be found to be groundless. The Lord Provost was thanked for his services.

ABERDEEN CORPORATION GAS SUPPLY.

REDUCTION IN THE PRICE OF GAS.

At a Special Meeting of the Aberdeen Town Council held last Friday, the report of the Gas Committee for the year ending Sept. 30 was submitted. The Committee recommended that the price of gas should be reduced from 3s. 10d. to 3s. 6d. per 1000 cubic feet. They estimated that the revenue from the sale of gas for the coming year, at the reduced rate, would be £51,625—a decrease of £3979 7s. 1d. as compared with last year. The return from the sale of residual products was estimated at £6600—an increase of £92 17s. 11d.; and from meter-rents of £2185, being about the same as last year. The total estimated revenue for the coming year was £60,410—a decrease of £4046 9s. 9d. On the expenditure side of the account, the estimate for the manufacture of gas was £36,850—an increase of £293 over last year; the cost of distribution, £2420—an increase of £450; the cost of management, including salaries, £1280—an increase of £28; and discounts on gas and bad debts, £1650—about the same as before. For depreciation £4000 was allowed—a slight increase on last year. The total estimated expenditure for the coming year amounted in all to £22,144. But there was a surplus of £4460 carried forward from last year's account; so that with a revenue of £60,410, the Committee considered there ought to be a surplus for the coming year of £2726, notwithstanding the substantial reduction in the price of gas. From a table of statistics published with the accounts for the past year, it appeared that the present is the largest reduction made in the price since the gas undertaking was acquired by the Corporation. In 1871 the rate was 5s. per 1000 cubic feet; in 1876 it was reduced to 4s. 10d.; in the following year it fell to 4s. 7d.; and it was gradually reduced until it was brought down to 3s. 10d. in 1884. In 1886 it was raised to 4s., at which figure it remained for two years, when the price again dropped to 3s. 10d., from which figure it has now been reduced to 3s. 6d. The amount of bad debts showed a reduction, the figure for last year being only £298 10s. 11d., compared with £661 5s. 4d. in 1877.

Mr. COLLIE, in moving the adoption of the report, said that last year the account closed with a favourable balance of £1145; and after reducing the price of gas 2d. per 1000 cubic feet, it was estimated that there would be a surplus of £1307. But this year's account showed, after providing £8148 for sinking, depreciation, and contingent funds, a balance of £3315, and, with the balance of the former year, made £4460 wherewith to commence the current year. The quantity of gas made this year was 325,515,000 cubic feet; the quantity sold, 294,721,300; and the sum realized was £55,604. Last year there were 286,342,100 cubic feet sold, yielding £56,076; being 8,379,200 feet more gas, but 472 less rental this year. The residual products were estimated at £5550; and the actual sum received was £6507—being an increase of £957. The unaccounted-for gas this year was 30,793,700 cubic feet; being scarcely 9½ per cent. They would see, by a new table introduced this year, that when the Corporation acquired the gas undertaking, the loss in this way was a little over 15½ per cent. The gas-stove department had not realized much profit. It had, however, answered its purpose in bringing about a more extensive use of gas for heating and cooking. The number of stoves at present on hire was 400; and a considerable number had been sold. The actual revenue from all sources amounted to £2131 more than the estimate. The expenditure for the working of the undertaking was estimated at £39,700; the actual outlay being £38,522—a saving of £1177. The capital account showed that the amount borrowed was £69,136; leaving £10,864 of additional borrowing power. The sum of £17,131 had been repaid by sinking fund, and £2138 by depreciation; leaving the present mortgage debt £49,867. The book value of the undertaking now stood at £143,339; being an increase of £28,406 since the purchase of the undertaking, while the works were capable of producing three times the quantity of gas. The capital expenditure had been increased by £1207, of which £2103 was for railway locomotives and waggons. The railway was a source of considerable saving in reducing carriage and checking the weights. The reserve and fire insurance fund stood at £6795. For next year the estimate had been made up carefully. Reckoning upon a consumption of 295,000,000 cubic feet, it was calculated that after reducing the price of gas to 3s. 6d. per 1000 feet the surplus would be £2726.

Mr. LYON failed to see why discount should be allowed to large consumers; and he wished to know if gas could be produced at such a rate as to allow a discount of 6d. per 1000 feet.

The Lord Provost said they would observe that only one consumer had this discount, and that was the City of Aberdeen; so that it simply went into the pocket of the community, and there was no hardship in allowing

the city a liberal rate of discount. With regard to the other large consumers who obtained a discount of 1d., 2d., and 3d. per 1000 feet, the Corporation followed the custom of other places; and, moreover, it prevented a good many large consumers from making their own gas. When people found they could themselves make gas cheaper than they could buy it, they would very soon do so; and he knew that many large consumers felt that they could produce gas at a lower rate than they had it in Aberdeen.

The report was adopted.

ELECTRIC LIGHTING AT BARNET.

The subject of the electric lighting of the town was again before the Barnet Local Board at their meeting last Tuesday. The Surveyor (Mr. W. H. Mansbridge) reported that all the lamps were burning at seven o'clock on the evenings of the 24th and 26th ult., but that on the 29th one lamp was not alight. In answer to a question, the Surveyor stated emphatically that the lights were no better than they had been. The question then arose as to whether the contractor was to have notice to terminate his contract, in accordance with the resolution passed at the previous meeting (see *ante*, p. 769). Some doubt was raised as to the exact drift of the resolution; the point in dispute being as to whether the Surveyor or the Lighting Committee were to determine as to "satisfactory" progress having been made by the contractor, on which the continuance of his contract was to depend. On the Clerk referring to his notes taken at the meeting, from which the minutes were afterwards fair copied, he announced that the words were, "If by this day week the engine is not fixed and satisfactory progress made," &c. The words "to the satisfaction of the Surveyor" did not, he said, appear. The result of this omission was that a decision on the subject had to be postponed, to allow the Lighting Committee to hold a meeting and prepare a report for presentation to the Board. One member proposed that the contractor should have notice there and then. His colleagues, however, refused to support him; and his proposition fell through. The Lighting Committee will report at the meeting of the Board to-day. With regard to the effectiveness of the light and its cost, a correspondent has written to a local paper pointing out that the slight improvement now noticeable in the lights in portions of the High Street appears to have been obtained at the expense of those in the side streets. On the point of cost he says: "The lighting of the side streets is execrable. The only real attempt at lighting is in portions of the High Street; and here the cost is very great. The gas-lamps—omitting those at the junctions of streets, which were kept alight all night and charged for at a proportionate increase—cost £2184 a year inclusive. The electric lamps substituted for gas are fewer in number, and each is charged at £5 8s. a year. A comparison of the relative cost of lighting the High Street by gas and electric lamps respectively (omitting in each case the junction lamps) shows that the electric light for one street alone costs about £27 a year in excess of gas. Townfolk may judge for themselves which is the best value for money and which system of lighting has proved most effective."

THE DUBLIN CORPORATION AND ELECTRIC LIGHTING.

A Special Meeting of the Dublin Town Council was held on Monday last week—the Lord Mayor (the Rt. Hon. Thomas Sexton, M.P.) in the chair—to receive a report of the Committee of the House on the subject of the Corporation applying for electric lighting powers. The report set forth the steps which had been taken since Oct. 17, 1887, to obtain a Licence to supply electricity for public and private lighting in the city. The fact was recorded that, on the 2nd of July last, the Council received a notice from the Alliance and Dublin Consumers' Gas Company of their intention, before the 21st of December next, to apply to the Board of Trade for a Provisional Order, under the Electric Lighting Act, 1882, authorizing them to supply electricity for public and private lighting within the municipal boundary. The report concluded as follows:—"Your Committee beg to recommend that effect be given to the object of the proposed meeting, as they are strongly of opinion that electric lighting power should not be left in the hands of the Gas Company. A Committee of the House of Commons has significantly reported that 'in the control of gas companies it may be anticipated that electric lighting would be of slow development.' Public policy, as evidenced in the framing of the Electric Lighting Act, indicates that the powers should be vested in the local authorities rather than in trading companies; and it was very clearly intimated at the recent conference at the offices of the Board of Trade, that in the event of applications under the Act being made for lighting powers, both by the Corporation and the Gas Company, a preference would be given to the application of the Corporation. Your Committee are also advised that the best and most prominent electric lighting companies would be more likely to tender for the lighting of thoroughfares, and at a cheaper rate, if allowed the option of private lighting; and, under these circumstances, beg to recommend that application be made to the Board of Trade for a Provisional Order, to enable the Corporation to supply electricity for private as well as for public purposes. Your Committee are also of opinion that any further steps which should be taken in the matter should be entrusted to a Special Committee, with all necessary powers to apply for the Provisional Order, to obtain estimates, and enter into arrangements with contractors and others, and do all necessary acts, subject to the approval of the Municipal Council."

The Lord Mayor moved the adoption of the report; remarking that the motion was merely a formal one, because at their meeting on the 22nd of October the Council resolved to take the necessary steps to procure the Provisional Order.

Mr. ROBINSON seconded the motion.

Mr. DENNEY contended that until the Corporation were assured that electric lighting would pay, they ought not to touch it. The Company established in the time of the late Mr. E. D. Gray had not been successful. He (Mr. Denney) had been opposed to the project from the commencement, and still disapproved of it.

Mr. P. DOWAN said the supplying of electric light to private establishments would be 200 per cent. more costly than gas. It was all very well for private companies to try it; but a municipality should be careful about doing so. Were the staff of the Gas Company to be disemployed, and were the Corporation to be paying the rates away to some English Company? He was not opposed to the lighting by electricity of large thoroughfares, but he saw no hope of their being able to have a turbine erected at Island Bridge; and if steam power should have to be resorted to, the expense would be enormous. The 45 lamps which it was proposed to have in Dublin would cost for maintenance £1000 a year.

Mr. DAWSON said the total risk they were proposing to run was a loss of about £280, which would be less than 0.1d. in the pound on the rates, while they would get, in the area in which the electric light was to be used for public purposes, fifteen times more light than they previously had. They should, in his opinion, secure powers for private as well as public lighting.

Mr. DENNEY: It is my intention, as a ratepayer, to place the matter

in the hands of a capable lawyer, and to endeavour to make the parties who promote it personally liable for any loss.

The Lord Mayor said they would be happy to meet Mr. Dennehy and his lawyer anywhere. As regarded questions of cost, the Committee would not enter on a single stage of the matter without carefully calculating the expense. The Gas Company were about to apply for the very same powers as the Corporation; and if they thought they could apply them with profit, would not the Corporation be able to do so without loss?

The motion was then put, and carried by a large majority.

GAS CONSUMPTION IN GERMANY.

In the Presidential Address delivered by M. Albert Ellissen at the Boulogne Congress of the Société Technique du Gaz en France, an abstract of which was given in the JOURNAL for June 26 last (p. 1146), he brought forward some interesting comparative statistics of the gas consumption per head of the population, as well as that used for public lighting, in London and a number of Continental cities and towns. Recent numbers of the *Journal des Usines à Gaz* have contained figures relating to places which were not included in M. Ellissen's list; and these it may now be useful to give. At Cologne last year the average consumption all over the city was 113·3 cubic metres, or 4000 cubic feet, per head. The city consists of two portions—one comprising the wealthy and business quarters, and the other the parts in which the less affluent classes are to be found, and where there is less business transacted. The annual consumption of gas per burner varies to the extent of 50 per cent. in the two districts. This will be seen from the following figures:—In 1887, the number of burners in use (taking the meters as an indication) in one case was 32,670, with a total consumption of 4,832,962 cubic metres (170½ million cubic feet), being 147·9 cubic metres per burner per annum; whereas in the other the number of burners was 73,215, with a consumption of 7,168,695 cubic metres (253 million cubic feet), being 97·9 cubic metres per burner per annum. The work of each burner is spread over 825 or 1200 hours per annum, according to the locality in which it is situated; that is supposing it to be employed exclusively for lighting purposes. According to Dr. Schilling (*vide* his "History of Gas Lighting in Bavaria," in the *Journal für Gasbeleuchtung*), the annual consumption of gas per head is as follows (stated in cubic metres) in the several places named:—Augsburg, 49·5; Nuremberg, 50·7; Hamburg and Dresden, 59·6; Leipzig, 69·5. Taking the consumption according to the total length of mains, the number of cubic metres of gas burnt per kilometre (1094 yards) in the preceding places is as follows:—Augsburg, 39,100; Nuremberg, 44,700; Hamburg, 89,500; Leipzig, 65,600. In Berlin it is 121,350 cubic metres; in Cologne, 122,200 cubic metres; and in Munich, 50,500 cubic metres. Dr. Schilling gives some very significant figures in regard to Bavaria. In order to produce the same quantity of gas, the number of retorts has been reduced as follows:—In 1862, there were 215 employed; in 1868, 202; in 1877, 148; and in 1887, 94. This amounts to saying that the annual production per retort has doubled in a quarter of a century. The gasholder capacity, which represented about 5 per cent. of the total annual production in 1862, equalled only 0·45 per cent. in 1868, and 0·37 per cent. in 1877. Last year, however, it was 0·41 per cent. These figures speak volumes for the progress of the gas industry in Germany in the past 25 years.

THE CENTRAL ELECTRIC LIGHTING STATION AT DEPTFORD.

In the JOURNAL last week, reference was made to the large central station which is being constructed by the London Electric Supply Corporation at Deptford, with the object of providing the Metropolis with electric light. As this is the most important installation of electric lighting plant for the public service which has been undertaken, a fuller account of the station than we have already given may be interesting to our readers. For this we are indebted mainly to particulars given in the *Electrical Review*. Before describing the plant, however, it will, perhaps be well to trace the steps in the progress of central station lighting in the Metropolis which have led to its establishment.

Our readers will remember that about four years ago Sir Coutts Lindsay decided to light the Grosvenor Gallery by electricity; and when this became known, many residents in the neighbourhood requested him to enlarge his proposed installation, and supply them with the electric light. This demand went on increasing, until at length a small Company was formed, and a large central generating station, which is known as the Grosvenor station, was built and equipped. From that station the electric current is now being supplied to about 33,000 lamps; the area covered extending from Regent's Park on the north to the River Thames on the south, and from the Royal Courts of Justice eastward, to Knightsbridge westward. The whole of this area is supplied with the electric current by five separate circuits. The Company which had initiated this movement became merged in the present Corporation, which consists of a very few subscribers, who have hitherto found the necessary capital among themselves, and, it is stated, intend to find it up to £1,000,000; this being the amount authorized.

The ground occupied by the Deptford station extends to between three and four acres abutting on the river, and adjoining the Steam Navigation Company's Wharf. The river frontage has been slightly raised, to obviate the danger of flooding the works at the period of an extra high tide. The depth of water along the wall at ordinary high tide is about 12 feet, which will float vessels of considerable tonnage. A 50-ton iron derrick has been erected on the wharf, to facilitate the unshipment of heavy materials, which are all brought by water and landed, then placed on trucks and conveyed on a railway to the buildings, and unloaded at any desired point. The railway will be permanently laid to run straight through the centre of the block of buildings comprising the boiler-house and the two engine-houses now being proceeded with. The buildings together in one block occupy a space of 210 feet by 195 feet, and in height will approximate to 100 feet.

The boiler-house, 195 feet long by 70 feet broad, is constructed to contain boilers of 65,000-horse power; and of these a number are now being erected to provide steam for engines of 13,000-horse power. These boilers are arranged on two floors; the upper floor being supported on iron pillars, 30 feet high. Above this floor will be another similarly supported, on which will be placed the store of fuel; and the supply to the furnaces will be by means of vertical shoots passing through the centre of the floors of the upper boiler-room to the lower ones. At each end of the boiler-house is placed a chimney-shaft, 130 feet in height by 24 feet by 18 feet area. The interior of the shaft is divided into four flues, one of which will be apportioned to every set of six boilers. The total number of boilers on the two floors will eventually be 48. Economizers are to be provided for use if required.

The two engine-houses are in dimensions nearly the same as the boiler-house, from which they are separated by a massive brick wall, and from each other by iron pillars of immense strength; and beyond these divisions, which are destined to carry the overhead travelling cranes and the several spans of the roof, nothing will exist to prevent an unimpeded

view of the whole of the engines—it being intended that the engineer in charge shall have a comprehensive view of the whole of the machinery from an elevated gallery specially provided for him. In the first engine-house a pair of engines of 3000-horse power will be erected in the course of a few weeks; they being in readiness and waiting until the roof, now in course of erection, shall afford them the necessary protection from the weather. These engines will actuate two Ferranti dynamos, each one capable of supplying current for 25,000 lights—by far the largest electrical generators that have yet been constructed. Some 60 feet overhead there will be a steam travelling crane capable of lifting 25 tons, which will traverse the building from end to end. Besides the machinery above mentioned, this section of the building will also contain the condensing and hydraulic gear, exciting dynamos, and other apparatus.

In the second engine-house will be placed what the Corporation's Engineer (Mr. Ferranti) calls the "large" engines and dynamos, of which there will be two sets. Here the dynamos and engines are combined in such a manner that the armature being placed on the shaft is driven direct at 60 revolutions per minute, and acts as a fly-wheel to the engines. There will eventually be four of these large dynamos, each having its pair of engines of 10,000-horse power; but at present only half the engine power will be applied to each dynamo. When the time arrives for the creation of more power by the addition of the second engine of each pair, these large dynamos will each have its engines of 10,000-horse power; and all future extensions of the plant will be in machines of this type. To give some idea of the size of these machines, it may be stated that the diameter of the shafts is 36 inches in the centre; the armature being about 45 feet over all, and the weight of the dynamo about 500 tons. For the manipulation of the heavy weights in these machines, an overhead steam travelling crane will be erected similar to that in the first engine-house, but with a lifting power of 50 tons.

The system to be employed will be the same that the Corporation have worked up to now—viz., the Ferranti generator of high potential separately excited; the high potential current thus produced being converted or transformed to such as will meet the requirements of consumers with varied wants. It is proposed, however, that the tension of the current from the Deptford centre shall be some four times in excess of that furnished from the Grosvenor Gallery centre. This high-tension current is to be brought to London at several points, to be called "distributing stations." At each of these points a first conversion will ensue—the transformation lowering the initial high tension; this lower-tension current will be finally transformed to a voltage necessary to run ordinary incandescent lamps.

On the occasion of a recent visit to the station by representatives of the Press, Mr. Ferranti, in describing the many particulars and details relating to the buildings, engines, dynamos, cables, &c., called attention to the fact that the installation being constructed at Deptford was the largest centre for the supply of electrical current in the world—vastly outstripping any one of the kind even in the land of big schemes, America; and it will also appear that the tension of the current to be supplied to the trunk main to London is to "whip creation" as well, as the current will be driven through the mains at a pressure of 10,000 volts. It was suggested that there might be some slight danger to person or limb from such a pressure. The suggestion was, however, answered by the statement that there was not really much more danger from 10,000 than from 2500 volts, considering that in either case a death would be recorded, should any person be unfortunate enough to undergo a shock at that potential. Every precaution is to be taken to avoid, or reduce to a minimum, the chances of such a mishap befalling anyone, by paying every possible attention to insulation throughout the circuit, and by other means.

Speaking about the insulation of his dynamos and cables, Mr. Ferranti said he had tried an experiment which proved that there was no probability of "sparking" through this insulation. The experiment quoted was one in which he employed a 6-inch spark for the purpose of breaking through a piece of ebonite. He found that, even when the material was reduced to the utmost tenuity, there was no permeability; and from this he deduced that the thicker insulation, as used in practical work, must afford absolute immunity from dangerous breakdowns through sparking. In practice, however, insulation is breaking down continually; proving conclusively that no laboratory tests on a small scale can be accepted with any degree of confidence. Nevertheless, on the strength of Mr. Ferranti's tests, it would seem that the Railway Companies have been induced to enter into agreements with the Corporation, permitting the latter to run their cables by the side of the lines. These agreements are entered into with the South-Eastern Railway and the London, Brighton, and South Coast Railway; also with the London, Chatham, and Dover Railway, by whose bridge at Blackfriars the leads will be brought across the Thames. The Corporation have also leave to run cables on any portion of the District Railway Company's line.

The cable to be put down as the trunk line is formed of two concentric copper tubes, 2½ inches outer diameter, with a special insulating material separating the tubes; the centre portion of the cable being hollow. The sectional area of each concentric tube is to be 0·5 of a square inch. The cable is constructed in lengths of 21 feet each; the several lengths are then connected by expansion joints similar to those used for steam-pipes. The outer tube is left bare. When an Act can be obtained, another cable is to be laid underground to the various distributing stations; as the second one will afford more security to consumers against an accidental mishap or total breakdown.

As already stated, the whole of the station, both architecturally and mechanically, has been designed by Mr. Ferranti personally. The first two Ferranti patent dynamos of 1500-horse power each are nearly completed, and will shortly be erected; and two dynamos of 10,000-horse power each will be completed in about five months. Mr. Ferranti, in designing the station and its details on the above principle, has space at disposal, now covered with buildings, capable of accommodating 40,000-horse power, and remaining space of ground, easily available without crowding, for another 80,000-horse power. This brings up the capacity of the three acres of ground, after everything has been provided for, to the very high figure of 120,000-horse power. It is anticipated that before the end of the present year there will be in actual operation at Deptford machinery capable of supplying 50,000 lights, and by the spring of next year 200,000 more; making, with those already being supplied by the Corporation from their Grosvenor station, a total of 283,000 lights.

FAVERSHAM GAS COMPANY, LIMITED.—This Company has been formed to acquire the undertaking of the Faversham Gaslight and Coke Company, together with all their land and property. The capital is £26,880, in £8 shares.

HAMOR LOCKWOOD, LIMITED.—A Company under this title has lately been registered, with a capital of £60,000, in £5 shares, to adopt an agreement made between Hamor Lockwood and Edward Whitehead Marshall (as trustee for and on behalf of the Company) for the purchase of the business of a tar distiller and manufacturer of various products of coal tar, carried on by Mr. Lockwood under the style of "H. Lockwood and Co."

THE POSSIBLE EXISTENCE OF COAL UNDER LONDON.

[From *The Times*.]

At frequent intervals during the last 40 years, the question of the existence of coal in South-Eastern England has come under the consideration of geologists, and been brought before the general public. In 1846 the late Sir Henry de la Beche wrote: "From the movement of the older rocks, many a mass of coal measures may be buried beneath the oolites and cretaceous rocks, or the last, the remains of a great sheet of these accumulations, connecting the districts we have noticed [the Mendip Hills, &c.] with those of Central England and of Belgium, rolled about and partially denuded prior to the new red sandstone." Since then the subject has been frequently discussed and speculated upon by geologists; the speculations being recently much assisted by several deep borings in London and its neighbourhood. The principal of these borings have been those of Kentish Town, 1113 feet; Meux's Brewery, at the corner of Tottenham Court Road and Oxford Street, 1002 feet; at Crossness, 1008 feet; and at Richmond, 1142 feet. Besides these, there have been other borings more or less in the London neighbourhood which have greatly helped geologists to surmise the disposition of the rocks underground in Eastern and South-Eastern England. There have been borings at Harwich, at Ware, at Dover, and in the Weald of Sussex—the last to a much greater depth than any other. With the exception of the Weald boring, which was a purely scientific undertaking, all these enterprises have had for their object the discovery of underground water. After going to a certain depth and meeting with various kinds of strata, geologists were able to say whether or not water existed. If it did, there was an end to the boring; if it did not, and the character of the rocks met with contradicted water (to use a medical term), then the boring was stopped, as it was not the intention of those who undertook it to carry the enterprise further. At the same time, none of the borings referred to, as is admitted by geologists, were exactly in the position likely to lead to coal within a reasonable depth.

It is well known that the productive coal measures never occur above certain other formations of more recent age. But in all the borings referred to, these newer formations have been of such a thickness, or the accompanying conditions were of such a nature, that coal has been practically unobtainable. Still, a comparison of the various borings, taken in conjunction with what we know of the geology of Southern England, of the Channel, and of the Continental regions bordering on the Channel, pointed to a probable thinning out of those formations overlying the coal series, and that thinning out reaches its most favourable conditions just under the southern districts of London. The case was well put by that acute geologist Mr. Godwin-Austen 33 years ago. "The depression of the Thames Valley represents," he wrote, "and is physically a continuation of that which, extending from Valenciennes by Douai, Bethune, Therouanne, and thence to Calais, includes the great coal-trough of these countries." He infers "that at an early time a line of disturbed surface was produced, having a general eastern and western direction, and which, traversing a portion of the area of the coal growths, has placed all the members of that series along its course either at or near the present surface;" and that "we have strong *a priori* reasons for supposing that the course of a band of coal measures coincides with, and may some day be reached along the line of the valley of the Thames, while some of the deeper-seated coal, as well as certain overlying and limited basins, may occur along and beneath some of the longitudinal folds of the Wealden denudation." This is essentially the position taken up by the best English as well as Belgian and French geologists—a position which has been, on the whole, confirmed by borings so far as they have gone. As was announced in *The Times* of May 16, 1877, by Mr. R. Etheridge, the boring at Meux's Brewery in that year showed that in nearly the centre of London rocks older than the carboniferous occurred at a depth of less than 1100 feet.*

It is not necessary, however, to follow the geological aspect of the question through all its intricacies. The argument is summed up by Mr. W. Whitaker, of the Geological Survey, in his forthcoming work on the geology of London:—"One of our greatest coal-fields is in the South, that namely, of South Wales. Eastward of this, and continuing along the line of the great disturbance that has resulted in bringing the older rocks within touch under London, is the Bristol coal-field. Much farther east again, and along the same line, are the coal-fields of Belgium and of the North of France. What evidence we have, therefore, seems to lead to two conclusions—that coal measures are likely to occur somewhere along the line of the Thames Valley, or in the neighbouring tracts, and that these coal measures are likely to yield workable coal. It is rash to attempt to foretell the future; but it seems to me that the day will come when coal will be worked in the South-East of England." To test the truth of this prediction and of all the theoretical speculations on the subject, an unusually favourable opportunity presents itself at this moment, just at the very spot where, if coal occurs at all, it is most likely to be found—viz., at Streatham, in the South of London. The case is well put in the following communication from Mr. Whitaker:—

"At the late meeting of the British Association at Bath, I drew attention to a deep boring in London, which is the third to reach the lower Jurassic rocks beneath the cretaceous beds. There is no need here to enter into details of the formations passed through, or into the many points of interest that have already occurred; my object in writing is to prevent a great chance of acquiring further knowledge from being lost. The boring in question has been made by the Southwark and Vauxhall Water Company at Streatham, and has so far proved the presence there of the following formations:—

	Thickness. Feet.	Depth. Feet.
London clay (with soil, &c.).	163	163
Lower London tertiaries.	78½	241½
Chalk.	623	864½
Upper greensand.	29	893½
Gault.	188	1,081½
Lower Jurassic limestone, &c.	13½	1,095

"The practical result of the boring is to prove the absence of the lower greensand in the southern part of London; the gault being underlain by an oolitic limestone (forest marble). Now, the object of the work was, after tapping the chalk, to reach the lower greensand and to get water therefrom. This object having been found unattainable, the Directors of the Company are considering the advisability of abandoning the boring, the chance of getting deep-seated water being apparently small, and depending perhaps on whether water from the lower greensand, further south may (somewhere underground) reach permeable Jurassic beds, and flow into them. In view of the possibility of the boring being speedily stopped, I venture to suggest to the scientific world that, though it may be abandoned for practical purposes (if water getting), it ought to be carried on as a scientific experiment, and one, moreover, which might have important practical results.

* From what we know, the Jurassic rocks are not likely to be very thick.

* An account of this boring, with an illustration showing the strata passed through, appeared in the *Journal* for June 19, 1877 (p. 973).

At Richmond they are about 57 feet; and at Meux's, only 64 feet. It is hardly likely, therefore, that they will reach to a much greater depth at Streatham; and probably 60 feet or 70 feet further boring might pierce them, and before this is in print the boring will have been carried somewhat deeper than now. The question to be solved is: 'What underlies the Jurassic beds?' Is it Devonian rocks, as at Meux's; is it red beds of doubtful age, as at Richmond; or may we find beds that will solve the question, 'Is there coal under the London district?' While the contractor's tackle is on the spot, surely some endeavour should be made to continue the work, and to add something to our knowledge of one of the greatest problems in English geology—the character of the older rocks beneath the secondary formations of South-Eastern England, and the possibility of the occurrence of coal measures in that tract. All our knowledge on the subject has as yet been got from the work of engineers in the search for water. Surely scientific men will not let slip such a chance of extending it! There is no time to be spared; and unless measures are speedily taken, a great opportunity may be lost. As no worthier and less personal use could be made of the 'Government grant,' administered by the Royal Society, it is to be hoped that some support may be forthcoming from that quarter."

It is not necessary to urge scientific men to support Mr. Whitaker's appeal. The gain to science by a few hundred feet more boring would be great. Surely at the same time practical men must see how important are the issues which hang on the completion of the present enterprise. The question of coal under London ought to be set at rest once and for all. The expenditure required for carrying the drill to a greater depth than has been reached is comparatively small; and even if coal should not be reached, the gain to science would more than compensate for the outlay. If coal in workable quantities could be reached, it might perhaps upset the amenities of Streatham; but the gain to the resources of England would far more than counterbalance any such consideration. Possibly, then, it might be worth inquiry whether the old iron industries of Surrey, Kent, and Sussex might not be revived.

NATURAL GAS COMPANIES AND THEIR CHARGES.

An important decision has lately been given by two Judges of the American Court (Judges White and Magee) in an action brought by the citizens of Allegheny, to prevent the Allegheny Heating Company, who supply natural gas for heating purposes, from cutting off the supply from consumers who decline to pay the increased rates sought to be levied. The Company claimed the right to determine what was a reasonable price to charge for their gas, and to fix the price; but the Judges thought that if a company could secure this right, and also a monopoly of the business, they would possess the power of being very oppressive in their dealings with the public. The first company organized in America for the supply of natural gas as fuel claimed a monopoly by the old Act under which they were working. This, however, was defeated by a decision of the Supreme Court to the effect that the Act did not authorize the incorporation of a company to supply natural gas for fuel; and the Judges suggested that in any Act that might be passed for the purpose no monopoly should be allowed. Then the Legislature passed the Act of May 29, 1885, section 2 of which expressly declared that neither it nor any other Act should be so construed as to confer, authorize, or give colour to any claim of exclusive right in any corporation, howsoever formed, dealing in any way or for any purpose in natural gas. In the case immediately in question, the plaintiffs had, at considerable expense, fitted up their houses for the use of gas under the prices settled at the time, with assurances that they should not exceed the cost of coal. For some two years this was the case; and as soon as the Company, by terms made with conflicting companies, secured a monopoly, they notified to all the consumers, that they must pay from 50 to 100 per cent. more, and sign contracts to this effect, or the gas would be cut off. The coal trade had been destroyed, competing companies got out of the way, and the plaintiffs could not get gas, coal, or other fuel without delay, inconvenience, and expense. What were they to do? Must they be compelled, the Judges asked, under the press of such circumstances, to sign contracts, and be bound hand and foot. The Court avowed its inability to determine whether or not the increased prices were reasonable. There were, as usual, affidavits by the plaintiffs to the effect that the charges were not only exorbitant, but wanting in uniformity. On the other hand, there were equally strong affidavits from the Company in support of their case. The Judges considered that the "perilous position" in which the plaintiffs had been placed required relief, if the Court could give it without prejudice to the defendant Company. In the absence of satisfactory evidence of any essential change in the circumstances, of a real necessity for an increase in the price, they thought fair to assume that the figure charged by the three companies for two years was a fair and reasonable one. They considered, however, that it would be wrong to fix the price, or to limit the Company to it. Substantial justice could be done to both parties, without injury to either, until the cause was fully heard and finally decided, by enjoining the Company from cutting off the gas from the plaintiffs by their paying the same rates and in the same instalments as before, and giving bond with surety satisfactory to the Company, or approved by the Court, in a sum three times as great as their annual gas bill, to pay whatever increased price, if any, might be finally determined, with the right of the Company, if an increase was finally allowed and the arrears of increase were not paid within 30 days, to discontinue to supply the gas, and proceed on the bonds to collect the arrears. In an action brought by certain consumers residing at Sewickley, against the Ohio Natural Gas Company, to restrain them from increasing the price of gas, Judge Magee expressed a similar opinion. According to the provisions of the ordinance under which the Company entered the borough, gas was to be furnished at 20 per cent. less than the cost of coal. The learned Judge thought it was evident from the affidavits of the Company, as well as from those filed on the part of the plaintiffs, that the increase would raise the price of gas to consumers considerably above the average cost of coal. Therefore a preliminary injunction was granted; and, pending the final settlement of the case, each consumer was to give bond with surety in a sum equal to the year's gas bill. The Companies will appeal to the Supreme Court; and the final decision will, of course, be anxiously awaited.

BIDDULPH PUBLIC LIGHTING.—At the last meeting of the Biddulph Local Board, the Clerk (Mr. Wade) said he had received a letter from the Biddulph Gas Company, to the effect that from the 1st of October the price of gas had been reduced from 5s. to 4s. 6d. per 1000 cubic feet, with a discount of 5 per cent. on all accounts paid within a month. The Company's Manager (Mr. A. Shires), in forwarding the letter, had stated that if the Board could see their way to erect a few street lamps (say, 50 or 60), the Company would supply the Board and the public at 4s. per 1000 cubic feet, and allow 5 per cent. on all accounts paid within a month. The Chairman (Mr. Heath) said he thought the suggested lamps were not required; and he moved that the further consideration of the matter be adjourned *sine die*. This was agreed to.

THE BURSTING OF A WATER RESERVOIR AT VALPARAISO.

Details are given in the *Chilian Times* of the disastrous bursting of a reservoir at Valparaiso on Aug. 11 last (already briefly alluded to in the *JOURNAL*), through which a large number of lives were lost, and much damage was done to property. The reservoir was situated in a ravine at the head, or nearly so, of the ravine dividing the Bellavista and Yungai Hills, and at an elevation of about 900 feet above the level of the sea. Its capacity is estimated to have been about 64,000 cubic metres, or about 14 million gallons. The reservoir was formed in the simplest manner possible by constructing a dam across the ravine, to collect the water from a few insignificant little rivulets flowing from springs and the rain water from the natural shed formed by the hills and the slopes of the ravines in the rear of the reservoir. The dam for the retention of so large a body of water as is represented by 14 million gallons was constructed of earth only; and its dimensions are reported to have been 165 feet in length, 56 feet in height, 132 feet thick at the base, and 20 feet at the top. The reservoir was made about 15 years ago; and two or three years since the proprietor solicited and obtained permission from the authorities to add 13 feet to the height of the retaining wall—thereby largely increasing its capacity, and augmenting enormously the risk to be apprehended from the possibility of the dam giving way. Considering the nature of the material of which the dam was constructed, without, so far as is yet known, any precaution having been taken to consolidate the earth or to bind it together, its destruction was, the local paper says, merely a question of time. The catastrophe, however, appears to have been precipitated by a landslide on the side of one of the hills overhanging the reservoir. It is supposed that the enormous quantity of earth which thus fell at a blow into the surcharged reservoir, produced such a violent commotion in the water, that the wall, already weakened by filtrations, and strained to its utmost, was unable to resist the sudden tension caused by the falling earth, and gave way under the pressure. Of course, the breach once begun, the destruction of the dam was the work of a moment. Fortunately for the city, below the reservoir an embankment had been formed for a road to divert traffic from a vegetable garden owned and cultivated by the proprietor of a neighbouring brewery. Into the hollow thus formed by the embankment, and containing the garden, the water rushed, and spent a considerable portion of its force. At the expiration of about half an hour, the water in the hollow began to flow over the top of the embankment, and shortly afterwards this gave way, and the frightful work of destruction began. The pent-up water, freed at last, rushed down the ravine dividing Bellavista and Yungai Hills with resistless force, carrying everything before it—sweeping away houses and human beings, and inundating a large area of the city with a seething sea of liquid mud. The catastrophe was so sudden and so unexpected that there was no opportunity for warning of any kind; and some time elapsed before it became known to what cause the sudden irruption of water which had inundated the streets was owing. After the first rush of water had passed, the news spread that the sudden irruption was owing to the bursting of the reservoir near the brewery; and the people began to collect from all quarters, and the authorities commenced taking measures to ascertain the extent of the disaster. Their investigation revealed the fact that it had been attended by a serious destruction of life and property. Some of the incidents of the catastrophe, as well as several marvellous escapes, are recorded in the paper from which the foregoing particulars have been taken; and the perusal of them causes the mind to revert to the calamity of a similar; but more appalling nature, which befell Sheffield in 1864, when the bursting of the Dale Dyke reservoir caused the loss of about 250 lives, and of property valued at half-a-million sterling. No estimate has yet been made as to the value of the property destroyed at Valparaiso.

RICHMOND (Yorks.) GAS AND WATER SUPPLY.—At the meeting of the Richmond (Yorks.) Town Council last Wednesday, Mr. Alderman Mason read the report of the Gas and Water Committee. It stated that the gas undertaking had progressed satisfactorily during the past 20 years; the consumption of gas having increased from 3,489,509 cubic feet, at 5s. per 1000 feet, to 8,700,600 cubic feet, at 3s. 9d.; the cost in the former case being £872, and in the latter £1631. The Gas Committee, having now ample storage, proposed to abolish Sunday labour entirely. As to the water undertaking, the Council were asked to renew the pipes throughout the town, which have been down about 50 years, at a cost of £650; but this matter was deferred. The remainder of the report was adopted.

THE BLYTH GAS COMPANY AND THE COWPEN LOCAL BOARD.—An extraordinary general meeting of the shareholders of the Blyth Gas Company was held last Tuesday evening, having been convened by the Directors in compliance with a requisition recently addressed to them by several shareholders, for the purpose of considering the dispute between the Directors and the Cowpen Local Board, to which several references have been made in our columns, and of passing a resolution thereon. The Chairman of the Company (Mr. W. Thompson) presided. As the meeting was deemed to be a privileged one, as far as the remarks of the shareholders are concerned, we can only record the fact that a resolution was passed to the effect that an offer should be made to the Local Board to appoint three of their number to meet an equal number appointed by the shareholders of the Company to discuss the matters in dispute between the two bodies, with a view to adjusting all differences. This step should lead to an amicable settlement of the quarrel, and the speedy restoration of gaslight to its accustomed place in the public lamps.

DAMAGE TO THE COATBRIDGE GAS COMPANY'S PIPES BY SEWERAGE WORKS.—In the Airdrie Sheriff's Court some time ago, an action was brought against the Coatbridge Corporation by the Coatbridge Gas Company for damages for alleged loss of gas and injury to their mains in St. John Street, arising out of the sewerage works of the Corporation in that street. The amounts claimed were £14 1s. 3d., the value of 75,000 cubic feet of gas lost; £6 6s., for "time and labour" rendered necessary by the Corporation's "faulty operations;" and £69 3s. for gas lost and labour expended prior to Dec. 29, 1887. The Corporation denied their liability; averring that their operations were carried on with the assistance and under the supervision of skilled workmen employed by the Company. Sheriff Mair, in a note appended to his judgment, allowed the parties a proof as to the first two claims. The third, however, was, he said, in a different position. The Company claimed £67 10s. for 360,000 cubic feet of gas and £1 13s. for time and labour; but, in addition to denying their liability, the Corporation pleaded that the action was excluded by the provisions of section 116 of the Public Health (Scotland) Act, 1867, under which they acted, whereby claims for damages were limited to £50. His Lordship therefore held that the action would be incompetent as far as this claim was concerned. The Company had offered, with a view to having the matter settled, to restrict their claim to £50. He could not, however, see his way to sanctioning this arrangement, as the effect of agreeing to the Company's proposal would, he said, alter entirely the character of the action. Their course would be to bring separate actions—one for the first two claims, and another (a summary application) for the third.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

A strike is threatened of the workmen employed in the Leith Gas-Works; and as the position in which the parties are now placed is so decidedly due to the action of the Commissioners, I feel that it will require some space to lay it rightly before your readers. Several weeks ago the workmen at Leith petitioned the Gas Commissioners to be restored, in the matter of wages, to the same position as they were in before May, 1886. The Finance Committee, to whom the question was sent for consideration, for some reason reported only with reference to the retort men; and their recommendation was to inform the men that they must first of all approach the Engineer, Mr. Linton, on questions such as that before them. This I considered to be a sensible suggestion; and so did the majority of the Commissioners, for it was adopted by a large majority. In discussing the matter, however, a great deal of mischief was done by the remarks of several of the Commissioners; but chiefly of Bailie Cranston, who has of late shown himself more than usually solicitous to win the favour of the working-class citizens. In the Bailie's view, the Commissioners should settle all such questions themselves; and he strongly urged this view upon the members. The effect of his remarks was soon apparent. The workmen assembled, and passed a vote of thanks to him; and then they turned to the Engineer and claimed, not restoration to their former position, but to be placed on the same footing as their brethren in the Edinburgh works. This was a much more serious matter than had been left in Mr. Linton's hands to deal with; and he was justified in referring, as he did, to the Commissioners for advice. In considering the subject, the question of what was paid in the Edinburgh works naturally arose; and, on discovering that a higher rate was paid in Edinburgh than in Leith, several of the Commissioners hastily jumped to the conclusion that the Leith men ought to be advanced to the same position as those in Edinburgh. Incredible as it may seem, the Commissioners were on the eve of agreeing, without consideration, to this proposal, when the ordinary common-sense view, that the wages paid in both works should be considered together, was introduced by Mr. Kinloch Anderson, supported by Mr. J. C. Dunlop, and ultimately adopted. Meantime, it was agreed that the retort men were to receive the advance they asked for. This was the weak point in the finding of the Commission; for the men being, as Bailie Roberts expressed himself, "set on edge" by the injudicious remarks of the Commissioners, now refuse to accept the concession as it is offered. The retort men met at the breakfast hour this morning; and afterwards gave notice that, unless the advance were conceded to all the *employés* in the works, they would strike next Friday. There are about 60 retort men and 120 other *employés*. The Commissioners have thus the prospect of a strike before them in the beginning of winter, and all through their own doing. It was not to be expected that men in Leith would do the same work for less wages than were paid in Edinburgh. A question of this nature arising in a business house would have led to inquiry and calculation as to whether it could be afforded. Instead of that, the Commissioners—at least some of them—began to deliver popular speeches on the rights of the workmen; and the result has been to raise a hornets' nest about their ears, which they may have difficulty in allaying. It is not likely that the *employés* in the Edinburgh works will take meekly to a reduction, should that be proposed; and in Leith the clamour will not subside until the men are placed on the same footing with the Edinburgh men. If the "levelling up" process be adopted, that means that men who only asked for £395 a year will have been stirred up to demand, and will have obtained, £2500 instead. If the "levelling down" of the Edinburgh men be adopted, neither group of *employés* will be satisfied; and still less will this be the case if it be attempted to produce equality by reducing the one and raising the other to the same figure. Either way, the Commissioners have not a very cheery prospect before them.

At this season of municipal elections, of all seasons in the year, the "great unwashed" must realize what glorious privileges they possess under representative government; for are they not, by Act of Parliament, at this time raised to the level of, if not above, the rulers and administrators of their district? and are they not entitled to interrogate and to censure these "delegates" as to their past shortcomings, and even to instruct them as to their future policy? Gas and water supply are never-ending topics of discussion at gatherings for such purposes; and at the numerous meetings during this week they have not been forgotten. Indeed, so many have been the references, that I can only here refer to a few. The most important question in my district arises at Arbroath. I dealt with it last week, when it was before what might be called an informal meeting of the inhabitants. Since then the regular nomination meeting has been held, at which Provost Anderson gave a most lucid account of the proceedings. The meeting adopted a resolution, proposed by Mr. Michie, that nothing should be done to the gas-works, except what was actually necessary. Provost Anderson took exactly the same view as was urged in Edinburgh last year—that the community were not competent to pronounce upon such a technical matter as the necessity for extending the gas-works; and, on the other side, the obtaining of reports from gas managers was denounced, on the ground that from a sense of brotherhood they would naturally support Mr. Carlow in his efforts to get the works into better condition.

At the municipal meetings at Aberdeen, the principal question discussed has been that raised by Mr. Adam Pratt as to alleged overcharges for gas. In connection with this the Committee who, along with Mr. Pratt, are responsible for the agitation, put a series of six questions to the candidates on the subject, the answers to which were various; but the thing which should give most comfort to the Gas Committee is that although efforts were made to bring forward candidates, the agitators have not had much success, so far as has yet appeared—Mr. Pratt himself being the only person nominated by them. His nomination is a wise course, because it will furnish the true test as to whether or not the public have confidence in the gas management. The fact that they have been able to reduce the price of gas from 3s. 10d. to 3s. 6d. per 1000 cubic feet is in favour of the Gas Committee, and so it must be conceded that Mr. Pratt is fighting with long odds against him; but, apart from that, he does not seem to have much hold on the community.

At the public meetings in Dundee, a good deal of cavilling has taken place at the honorarium of £500 given to Mr. J. Watson, the Water Engineer, for extra services in connection with the new Lintrathen water supply, and that, too, in the face of the explanation that the fee to an outside engineer would have been £5000, and that Mr. Watson had done his work so carefully that scarcely £5 worth of extra work had been required.

Following up the question of the dilution of the Dundee gas with air, which I referred to the other week, a correspondent in the local papers accuses the management of using too much shale in the manufacture, and insinuates that the coal is supplied by a member of the family of one of the officials.

The latter statement has been authoritatively denied; but the accuser does not accept the denial, and replies that "it may also be true that the person hinted at has an interest in some way or other in the supply of this particular kind of coal." Whoever the individual may be, he does not seem to deal very straightforwardly with the Gas Commissioners.

At the meeting of the Arbroath Town Council on Monday, it was reported that the surplus gas profits for the year were £180 2s. 2d.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

Considering the fact that a movement was made some time ago in the Airdrie Town Council for the acquisition of the local gas-works, and that it was eventually found advisable not to prosecute it to an ultimatum, it was natural to suppose that some of the members of the Council would take an opportunity of referring to the "gas question" when rendering an "account of their stewardship" to their respective ward meetings held in view of the forthcoming municipal elections. Referring to this question before the electors of the Third Ward, Bailie Martyn said that, after fully investigating the whole matter, the Council had found that it would be advisable in the meantime not to take over the gas-works. He had no idea as to what price the Gas Company would wish; and being in a great measure in the dark, if the proposal had been gone on with it would have had to be submitted to an arbiter, and they would have been obliged to accept his decision, whether it was a large sum or a small one. Considering also that the electric light was making such rapid strides, it had been found by the Airdrie Town Council advisable to postpone the matter. Mr. McKillop was the principal speaker on this subject at the meeting referred to. When he first appeared before the electors as a candidate, he said that he promised, if returned, to bring the matter up in the Council. As they were aware, he had fulfilled his promise. Six months ago he brought forward a motion, asking for the appointment of a Committee to consider the whole question. In doing so, he had left no stone unturned in order to support the case which he then presented. He showed first of all that in the different towns in Scotland—26 in number—where the experiment of taking the management of the gas-works into the hands of the corporations had been tried, success had invariably followed; that the price of gas in those places was lower than that charged in Airdrie; and that the surplus profit went for the purpose of reducing the rates. He then explained, he said, how the same could be done in Airdrie, if they followed the example of these towns. The original capital of the Airdrie Gas Company had been between £14,000 and £15,000, and according to the best calculation, arbiters would not compel them to pay more than about £24,000; so that, by borrowing the purchase-money at 4 per cent., the interest could be paid, the works kept in good order, and yet a handsome profit realized, which could be applied either for the purpose of reducing the general rates, or lowering the price of gas. After some difficulty, a Committee was appointed, and immediately set to work. As it was evident to him that the majority of the Committee were against the proposal, he felt that it would be madness to fight it to the "bitter end," and he therefore agreed to the recommendation of the Committee, that no action be taken in the meantime. It was still, however, an open question, he remarked; and if the ratepayers generally were in favour of the scheme, they ought to speak out, and impress the matter on their representatives. So far as he himself was concerned, his opinion was the same to-day as it was a year ago. Other speakers at the ward meetings during the week dealt briefly with the matter in question. One of them (Bailie Arthur) remarked that the decision came to by Mr. McKillop's Committee was a wise one, owing to the transitional state of the question of lighting, and the vast improvement of lighting by electricity; and he pointed out that even although they had the gas-works at their present market value, and that they showed a small margin of profit, yet in a few years they might have to face a diminished revenue to meet a large capital, and then be left, to use a popular phrase, with "the baby to hold." Mr. Knox, a member of the Council, said he had a strong opinion that it would be advantageous to the town to acquire the gas-works. In many cases throughout the country, he observed, the purchase of gas-works had proved far more successful financially to corporations than that of water-works; and he was still open to consider the question at the very first opportunity.

Mr. Nicolson, one of the Greenock Town Councillors, referred to gas affairs when addressing his constituents the other night. He was pleased to be able to say that the Gas Trust had proved to be a source of profit during the past year; a sum of £3000 having been, as formerly, used to reduce the Police Board rates. After a great deal of discussion on the question of reducing the price of gas, it was resolved that the charge should be lowered by 2½d. per 1000 cubic feet. Many of the members of the Board—himself among the number—were strongly in favour of a reduction of 5d. being made. He was far from being satisfied with the manner in which the profits derived from the gas undertaking were distributed; and he would far sooner see 21. or 3d. added to the rates, as there was no doubt by the present system many obtained benefit to which they were not entitled. He expressed the hope that next year a change would be made in this system. Had the profits derived from the sale of gas been used for reducing the debt on the Gas Trust for many years back, in a very short time it would have been clear of debt. At the meeting of the electors of the Fifth Ward, Mr. D. Shankland referred to the great saving which had been effected at the gas-works by the introduction of the Klönne system of heating retorts. At the same meeting, Mr. J. Lang stated that he had been looking into the matter of handing over the balance of profits derived from the gas undertaking to the Police Board (which he entirely disapproved of); and he found that since 1872 the moneys so paid amounted to £55,000. They had also set aside as a contingent fund the sum of £4468; for sinking fund, £28,014; and for redemption of mortgages, £7400—amounting in all to upwards of £93,000, which, he thought, showed that they had paid a high price for gas during these years.

The Glasgow pig-iron warrant market has been steady during the week. Scotch warrants have fluctuated in price between 41s. 1d. per ton cash (on Tuesday) and 41s. 7½d., at which there were buyers at the close yesterday afternoon. The fluctuations in the price of Cleveland and hematite iron have been within small compass. Scotch special brands are in quiet demand; and the current quotations range from 49s. 6d. per ton (Coltness) to 47s. per ton (Gartsherrie).

A steady progress in the way of improvement is showing itself in the local coal trade. The price of house coal has risen 6d. per ton within the past few days, in addition to the 1s. advance a few weeks since. In a number of instances the miners have obtained an increase of 6d. per day on the rate of wages; and it is probable that in a week or two the advance will be very general.

The Ilkeston Local Board have recently decided to apply to the Local Government Board for power to raise £6000 for the extension of their water-works.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Nov. 3.

Sulphate of Ammonia.—Although the market is still firm, there does not to-day exist the same amount of strong feeling as a week ago. In fact, consumers are hardly as eager to secure spot parcels or forward contracts; and the same may be said of dealers and speculators. The reason for this is readily apparent when it is considered how large an amount of business has been done during the past fortnight or three weeks; and that consequently consumers will have filled a fair portion of their requirements, while dealers and speculators may feel inclined to pause before committing themselves too extensively to the present considerably enhanced values. It can, however, scarcely be said that a decline of any importance is likely to ensue. For such an advent stocks are at present too low; and even a proverbially dull November (and a consequent rapid increase of the liquor supply) may not bring about any marked change, as many producers have sold fair quantities for near delivery, and will not be obliged to bring their sulphate to market till later in the month. Of course, November is generally one of the quietest months of the year; but, like October, the present month may prove that previous experience is ineffective. Nitrate keeps firm; and its large consumption will contribute to the maintenance of values during the ensuing season. At the close quotations stand at £12 2s. 6d. to £12 5s.

LONDON, Nov. 3.

Tar Products.—Business is better in this market; and products have in some instances improved both in request and price. Pitch is, however, not buoyant; and stocks are now increasing. Anthracene is weaker; but stocks of this article are low. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. 2d. per gallon; 50 per cent., 2s. 6d. Tolnol, 1s. 7d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 1d. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 3s. 5d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 5d. per unit; "B" quality, 1s. 3d.

Ammonia Products.—The improvement noted last week has developed into considerable strength. The extraordinary rise in the value of nitrate has brought buyers of that article into the sulphate market. Doubtless the sudden rise is immediately due to "bulling" operators. Large business has been done at £12 to £12 3s. 9d. per ton, less discount; and makers are asking more for forward delivery. Prices of other products may be taken as follows:—Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Nitrate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Nov. 3.]

Sulphate of Ammonia.—The sulphate market has for some time past been exceedingly firm; and prices have gradually risen until £12 2s. 6d. is easily obtainable at Hull, £12 at Liverpool, and £12 1s. 3d. at Leith. Beckett sulphate has, within a very short period, been twice enhanced in price. After doing a considerable business at £12, the price was raised to £12 2s. 6d.; and within a few days to £12 5s., at which it now stands. Much of the advance at provincial ports must be attributed to sympathy with the Beckett quotations; and makers should be mindful that the act of running up the price to-day might leave them short of customers for to-morrow. There is still, however, a good inquiry for spring delivery; and the nitrate market remains in a strong position.

Tar Products.—Benzol has somewhat recovered itself; and on 'Change last Tuesday, 90's may be said to have reached 3s. 1½d., while 50 90's could be bought for 2s. 5d. to 2s. 5½d. There is still a good demand for solvent naphtha at old rates; and creosote is moving off very quickly. Crude carbolic acid 60's is reported to be a little better; and 3s. 4d. to 3s. 4½d. is the price asked. Anthracene still keeps in good demand, and at slightly improved rates. Although the "A" quality is still unchanged in price, a slight improvement has taken place in "B" quality; and to-day's value may be taken as 1s. 3d. to 1s. 3½d. Very little, however, if any, can be obtained at the former price. Alizarine is now on the move upwards, and one of the largest producing firms has raised its price to 9½d. for the remainder of this year, and 10d. for next year. How this will affect the price of anthracene remains to be seen. A fair business is doing in pitch; and 14s. 6d. to 15s. 6d. may be taken as being the price to-day. It is reported that sales have been made in London of Beckett pitch at 16s.; and some makers are still anticipating higher prices.

DORTMUND GAS COMPANY.—The Dortmund Gas Company have just declared a dividend of 1½ per cent. on the past year's working.

BATH AND THE ELECTRIC LIGHT.—At the last meeting of the Bath Town Council, the question of the lighting of a portion of the city by electricity was again discussed. Alderman Gibbs said he considered the introduction of the light was premature; and they would do well if they waited until the system had been further improved. He thought it was a fair question whether the district lighted ought not to bear the increased expense, for, in his opinion, no call for the cost of the light should be made upon the poor ratepayers, who would not derive any benefit from it. It was pointed out that such a principle could not be applied as that suggested by Mr. Gibbs. After a long discussion, it was decided that the Corporation should have the power to buy the whole of the plant at the end of seven years, at a fair valuation.

THE NORTHERN COAL TRADE.—The coal trade in the North of England has shown very great activity during the past few days, partly owing to the continued scarcity of coal, which has been greatly increased by the effects of the strike in Yorkshire. A good deal of steam coal has been despatched from Northumberland to the Humber, and even farther south; and Durham house coal has been freely sent from the Castle Eden district to Leeds and other parts. In the gas coal trade, very great scarcity has shown itself. The consumption is growing with some rapidity, as the nature of the summer prevented the users from getting stocks such as they usually do; hence their desire to stock now freely. But some of the working miners are undoubtedly restricting their output. At one large colliery the production has been about 10 per cent. less than it usually is, and naturally some of the pits are in consequence behind with their contracts. For odd cargoes of coal high prices have had to be paid. Whilst two or three months ago the price of best coal was about 6s. 6d. per ton, 7s. 6d., and in one instance even 8s. per ton was paid last week; and the tendency is towards still higher prices. It has been said that 9s. per ton will have to be given before the end of the year. Every week for two months the consumption will increase, and of course much more coal will be needed. Household coal is in rather better demand. Prices of best steam coal vary from 8s. to 9s., less a discount. A good deal of gas coke is now being made; but the demand has increased as rapidly. The price is a little higher for the manufacturers who use it in large quantities.

REDUCTION IN PRICE.—The *Cleveland Gas Company* have reduced the price of gas 9d. per 1000 cubic feet; to take effect from the 1st ult.

SKIPTON WATER SUPPLY.—At the last meeting of the Skipton Rural Sanitary Authority, the Barnoldswick water difficulty formed the subject of a rather animated discussion. A report was read from Mr. De Rance, recommending that the boring operations for water, recently discontinued at a depth of 300 feet, should be resumed. The recommendation was ultimately agreed to; and it was resolved that the engineers be instructed to obtain tenders for the work.

THE COST OF THE VYRNWY WATER-WORKS.—The quarterly return of expenditure by the Water Committee of the Liverpool Corporation, under the Liverpool Corporation Water-Works Act, 1880, has been issued. It is for the three months ending Sept. 30, during which period £45,725 10s. 3d., was expended in connection with the Vyrnwy water-works. This amount is made up as follows:—Llanwddyn embankment works, and works in connection with the reservoir, £9685 10s. 1d.; Llanwddyn quarry, £2022 17s. 7d.; aqueduct, £29,373 18s. 1d.; land and easements, £3267 7s. 8d.; and maintenance of the Vyrnwy estate, £1375 16s. 10d. The total expenditure since the commencement of the works now reaches the sum of £1,812,976.

WESTON-SUPER-MARE WATER-WORKS.—The new pumping station and extension of existing mains, which were found to be necessary in consequence of the consumption of water having increased to such an extent as to almost reach the limit of the existing water supply at Weston-super-Mare, are rapidly approaching completion, and will be ready for use in about two months. The new works have been in hand something like two years, and have been carried out from the designs of Messrs. E. Cousins and Son, of Westminster. The pumping station is about a mile outside the town, between the Worle and Bristol roads. One well has been sunk 40 feet deep, with three adits, driven in different directions into the old red sandstone; the collecting supply being the watershed of the Mendip Hills, covering an area of 60 square miles. The water is pumped into two reservoirs—one being 200 feet and the other 450 feet above the surface. The engines and pumps are capable of lifting 40,000 gallons of water per hour. They are condensing, and are in duplicate, and the pumps are of the direct-action bucket-and-plunger type. On the completion of the new works, the existing machinery will be used only as an auxiliary.

TENDRING HUNDRED WATER COMPANY.—The first annual general meeting of this Company was held last Tuesday—Capt. Parsons, Chairman of the Directors, presiding. The Chairman presented the Directors' report, with the accounts to June 30 last, and gave an outline of the progress made in carrying out the objects of the Company; congratulating the shareholders upon the completion of the mains to Dovercourt, Harwich, Thorpe, and Frinton-on-Sea. He stated that a plentiful supply of very pure water continued, and that there was a gradual increase of income, both from domestic and public supplies. Every prospect existed of a speedy completion of the whole system of works contemplated in the Company's Acts; and he predicted that financially and otherwise the future of the Company would be successful. The Directors considered that the proper course was to carry forward to the next year the balance appearing on the revenue account. The Chairman concluded by moving the adoption of the report and accounts. Mr. Field seconded the motion, and it was carried unanimously. Mr. P. S. Bruff and Mr. Newson Garrett, the Directors retiring by rotation, were re-elected; as were also the Auditors, Messrs. R. S. Barnes and C. E. Bland. The proceedings terminated with a vote of thanks to the Chairman.

WAKEFIELD WATER SUPPLY.—A special meeting of the Wakefield City Council was held on Monday last week, to consider a resolution authorizing the Corporation to promote a Bill for additional powers in relation to the new water-works, extending the time for the construction of the Green Withens reservoir, catchwater, conduit, and other works not yet executed, authorizing certain alterations, empowering the Corporation to issue various classes of stock, and directing that the expense of promoting the Bill shall be charged upon the rates, water revenue, &c. The Mayor (Mr. Alderman Henry Lee), who is Chairman of the Water Committee, explained that the period allowed to the Corporation for carrying out the construction of the Green Withens reservoir and other works will expire next year; and it was of vital importance that they should proceed with the work or obtain an extension of time. If they allowed the present opportunity to pass, it would be a most suicidal act on the part of the Corporation. When the proposed works had been carried out, the cost of the water supply in bulk to the Corporation would be about 2d. per 1000 gallons less than at present, and they would then be able to entertain applications for water which they were now receiving from places all along the line of their pipes, and the supply to Wakefield would also be increased. The Mayor also explained that the scheme as originally devised by Mr. Filitler had been somewhat varied and remodelled by Mr. Rofe, his partner; and Mr. T. Hawksley had approved of the alterations. On the motion being put, all the members present voted for it. A resolution was then passed referring the matter to the Parliamentary Committee to arrange the various preliminaries.

THE BOLTON CORPORATION GAS COAL CONTRACTS.—At a meeting of the burgesses of the North Ward, Bolton, last Tuesday, Mr. Tootill made a speech in which he said that some five weeks ago he was present at the meeting of the Gas Committee held at the Lum Street works, where a tender for the coal contract had been sent in by the Hulton Colliery Company. There were gentlemen on the Committee who were in some way or other interested in that concern. But in consequence of the tests with respect to the coal proving unsatisfactory, it was decided in his (Mr. Tootill's) presence, and he voted against the contract being accepted. On the previous Friday, however, to his surprise, when the minutes were read, it appeared that the contract had been accepted. He at once called attention to the irregular and unbusinesslike way in which the matter had been conducted. Such things, he said, could not be tolerated; and as to what took place in the interim they could judge for themselves. Mr. J. Partington, the agent of the Company, has written to the local papers denouncing Mr. Tootill's statement as a "pure falsehood." He says there is not a member of the Gas Committee either directly or indirectly interested in the Company, and that the original tender was not declined because of any test, but was left over on account of the price asked being more than the Committee felt inclined to give. "What Mr. Tootill means to insinuate," continues the writer, "by leaving his audience to judge 'as to what took place in the interim' is best known to himself; and he will either give a further explanation or not, as he thinks best. My opinion is that the members of the Gas Committee can afford to treat such cowardly insinuations with the contempt they merit." Another statement made by Mr. Tootill, as to a suggested reception of fees when he was on the Sub-Committee dealing with the question of mechanical stokers, has drawn a reply from Mr. Alderman Miles and Mr. Braughton. They repudiate the insinuation against themselves, and promise to "deal further" with the matter.

GAS-CONTAMINATED WELLS.—It is reported that, owing to the defective condition of the gas-pipes in the Clarence Victualling Yard at Gosport, the water in the wells has become so contaminated as to be useless, and the wells have consequently been ordered to be closed.

THE PROPOSED EXTENSION OF THE BURNLEY GAS-WORKS.—At a special meeting of the Burnley Town Council last Wednesday, a resolution was passed for the promotion of a Bill in Parliament to authorize the extension of the borough boundaries, and to confer further power upon the Corporation with respect to their gas-works. We have already referred in detail to the proposed extension of the gas-works, which has been necessitated by the increasing population of the town.

THE OIL LIGHTING EXPERIMENT AT ERITH.—When Messrs. Defries contracted to light the public lamps of Erith with oil at a rate which occasioned considerable comment at the time, on account of the lowness of the figure, they agreed with the Local Board to purchase old lanterns at 5s. 9d. each. They have now had to ask the Board to accept a smaller sum than the one named, as they have found it impossible to dispose of the lanterns at the price. The Board, however, have refused to accept anything less than the amount agreed upon. Altogether, the oil-lighting experiment at Erith does not seem to be a very brilliant one for the contractors.

THE METROPOLITAN BOARD OF WORKS AND THE COAL AND WINE DUES.—The *Financial News* thinks it is very kind of the Metropolitan Board of Works to go out of its way to commit the forthcoming County Council by taking steps to promote a Bill for the renewal of the Coal and Wine Dues, to which reference was made in the *JOURNAL* for the 23rd ult. Our contemporary thinks it would be better for the Board to devote the few remaining days of its life to repentance, instead of seeking to fasten upon its successor the legacy of its own blunders. The Board of Works and the dues are, it says, both doomed.

NEW GAS-WORKS AT HORWICH.—The Lancashire and Yorkshire Railway Company are now, after considerable difficulty, able to supply gas to their extensive works at Horwich, near Bolton. Their new gas-works there have been in course of construction for two or three years; but the vast quantity of water found on the site proved a great difficulty. Now, however, an iron outer shell has been fixed in connection with the gas-holder, and the process of gas manufacture is proceeding satisfactorily. The contractors for the brickwork of the new works have, it is reported lost considerably in consequence of the water difficulty.

GWYNNE & CO., ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS & ENGINES.

Telegrams: "GWYNNEGRAM, LONDON." Telephone No. 2698.

Exhausters of nearly all sizes in Stock.

Prize Medals at all the Great International Exhibitions.

Exhausters equal to a total capacity of more than 26,000,000 cubic feet passed per hour have been supplied by us.

Our new Patent Non-Fluctuating Exhausters, to work without the slightest oscillation or variation in pressure, are strongly recommended.

MAKERS OF EVERY DESCRIPTION OF HYDRAULIC AND GAS MACHINERY.

Gwynne & Co.'s New Catalogue and List of Testimonials can now be obtained on application.

Exhausters and Vertical Engine as supplied for both the Fulham and Bromley-by-Bow Stations of The Gaslight and Coke Company.

We supply only the very highest quality of Machinery; and our Exhausters are constructed of large size to run at slow speeds.

OXIDE OF IRON.

O'NEILL'S Oxide has a larger annual sale in the United Kingdom than all other Oxides combined. Purity and uniformity of quality guaranteed. Pamphlet, "How to Purchase Bog Ore," to be obtained on application.
Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C.
JOHN Wm. O'NEILL, Managing Director.

ANDREW STEPHENSON, Agent for the GAS PURIFICATION AND CHEMICAL COMPANY, Limited, Palmerston Buildings, Old Broad Street, London, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH.
Gas Engineers, supply all the most approved SCOTCH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.
Prices, &c., will be forwarded on application to No. 30, ST. ANDREW SQUARE, EDINBURGH, } SCOTLAND.
No. 54, BERNARD STREET, LEITH, }

SULPHURIC ACID.

HUGH WALLACE & CO., Chemical Manufacturers (the old-established firm), supply the above, which is specially adapted for making White Sulphate of Ammonia. The latter purchased in any quantities at highest market prices, or contracts for the year.
For price and terms apply Botolph House, Eastcheap, LONDON, E.C.

GAS-WORKS of any magnitude leased, at premiums ranging from 5 to 10 per cent., according to the size of the Works. Gas-Works erected or re-modelled upon the most modern principles.
Address **GEORGE WELLER**, Gas Engineer, St. Ives, CORNWALL.

ADVERTISER desires an Appointment as SECRETARY, MANAGER, ASSISTANT, or any place of trust. Thorough knowledge of Gas Manufacture, Distribution, and Sulphate of Ammonia Production. Good Accountant, and has a knowledge of Shorthand. Age 25. First class testimonial and references.
Address No. 1654, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

JUNIOR CLERK.

WANTED, immediately, by a Gas Company in South Wales, a JUNIOR CLERK. A knowledge of Bookkeeping upon the Double-entry System and the Accounts of a Gas-Fittings Department indispensable.
Applications, stating age, qualifications, where now employed, and giving references as to character and ability, to be addressed (before the 12th inst.), in the first place, to No. 1655, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

FOREMAN STOKER.

WANTED, an intelligent young Man, capable of producing best results, and used to Shovel Charging. Wages 26s. per week, with House, Rent, Gas, and Water free.
Apply, in own writing, to No. 1653, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WANTED, a Second-hand "Otto" GAS-ENGINE, in good working order.
Give size and full particulars, and state lowest price, to R. S., care of C. Birchall, Advertising Agent, LIVERPOOL.

WANTED, 80 to 100 Gas Columns and LANTERNS.
Send particulars, with Sketch, Weight, and Price, delivered at Woodiesford, to MANAGER, Eshaldwell Brewery, Woodiesford, near LEEDS.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.
For Prices apply to JAMES LAWRIE AND CO., 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWALL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56 MILLBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.

* * See Advertisement on Page III. of the Wrapper of this week's issue.

W. C. HOLMES & Co., Huddersfield, AND 80, CANNON STREET, LONDON,

Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. A'so for Collingwood's Regenerative Retort-Settings.
* * See Advertisement p. 784 of last week's issue.
Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas-Works prepared by R. D. Gibbs, Summersfield Crescent, Birmingham.
Analysis of Coal, Oxide, and all Gas Materials.

PARTNERSHIP.

AN Old-Established Firm of Gas Engineers and Contractors, in consequence of extended business, offer an opening for a PARTNER with moderate capital.
Address P. A., Box 6002, Sell's Advertising Offices, LONDON.

FOR SALE—Experimental Coal-Testing APPARATUS (second-hand).
For particulars and price, apply to HUTCHINSON BROTHERS, BARNLEY.

GAS SHARES IN THE ENFIELD GAS COMPANY.

NEW ISSUE OF SHARES BY ORDER OF THE DIRECTORS.

MR. ALFRED RICHARDS will Sell by Auction at the George Hotel, Enfield Town, on Wednesday, Nov. 14, 1888, at Six for Seven o'clock precisely in the evening, in lots of 10 shares each, 200 £10 FULLY PAID SHARES (maximum dividend 7 per cent., now paying 6 per cent.) in the ENFIELD GAS COMPANY.
Particulars may be obtained of Mr. J. PUNDEY, ENFIELD TOWN, and of the AUCTIONEER, TOTTENHAM, and 8, NEW BROAD STREET, E.C.
(BY ORDER OF THE ROYAL COLLEGE OF SURGEONS.)

CRYSTAL PALACE DISTRICT.

SALE OF GAS SHARES.

THURGOOD & MARTIN have received instructions to Sell by Auction, at the Auction Mart, Tokenhouse Yard, E.C., on Thursday, the 6th of December, 1888, at Two o'clock precisely, in 219 lots cum dividend, £24,780 in the STOCK OF THE CRYSTAL PALACE DISTRICT GAS COMPANY, producing Dividends at the rate of 10 per cent., 7 per cent., and 6 per cent., respectively; also 375 £6 FULLY PAID 7 PERCENT. SHARES in the Capital of the same Company, which is a specially safe and easy investment for large or small sums, the dividends being secured against fluctuation by ample Reserve and Insurance Funds, and the increasingly profitable district of the Company.
Particulars and Conditions of Sale may be had of MESSRS. WILKIE, BERNER, AND MOORE, 21, COLLEGE HILL, E.C., Solicitors; at the PLACE OF SALE; and of the AUCTIONEERS, 27, CHANCERY LANE, W.C.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.
Highest References and all particulars supplied on application.

JOHN RILEY & SONS, Chemical Manufacturers.

Hapton, near Accrington, are MAKERS of SULPHURIC ACID, from Brimstone, for Sulphate of Ammonia making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitrol. References given to Gas Companies.

TENDERS FOR TAR.

THE HUYTON and Roby Gas Company are prepared to receive TENDERS for surplus TAR made at their Works at Huyton Quarry during the year ending the 31st of October, 1889.
The probable quantity will be about 120 tons, and will be delivered into the Contractors' Railway Tank-Wagons at Huyton Quarry.
Sealed tenders, addressed to the undersigned, and endorsed "Tender for Tar," to be sent in on or before the 10th of November next.
By order,
FRED. PRITCHARD,
Secretary and Manager.
Gas Offices, Huyton Quarry, Oct. 30, 1888.

THE Corporation of Middleton are pre-

pared to receive TENDERS for the Supply of about 800 yards of 3-inch, 600 yards of 4-inch, and 600 yards of 6-inch TURNED AND BORED GAS MAINS.
Full particulars and specification may be obtained on application to Mr. Hartley, Gas Manager, Middleton.
Tenders addressed to the Chairman of the Gas Committee, endorsed "Tender for Mains," to be delivered at my Office, on or before the 17th of November, 1888.
The Corporation do not bind themselves to accept the lowest or any tender.
FREDERICK ENTWISTLE, Town Clerk.
Town Clerk's Office, Middleton,
Near Manchester, Oct. 31, 1888.

BOROUGH OF BARROW-IN-FURNESS.

TAR AND AMMONIACAL LIQUOR.

THE Corporation are prepared to receive TENDERS for the purchase of the surplus TAR and AMMONIACAL LIQUOR produced at their Gas-Works from the 1st of January next to the 31st of March, 1890.
Approximate quantity: Tar, 850 tons; Liquor, 1800 tons—delivered into Contractors' Tank-Wagons at the Gas-Works Siding.
Tenders for Tar to be at per ton; tenders for Liquor to be at per ton of various strengths—viz., 4½, 5, 5½, and 6 degrees of Twaddell's hydrometer when tested at a Temperature of 60° Fahr.
Any further information may be obtained on application to Mr. W. Fergusson, Manager, Gas and Water Works, Barrow-in-Furness.
Sealed tenders, addressed to the Chairman of the Gas and Water Committee, and endorsed "Tender for Tar and Liquor," to be delivered at the Town Clerk's Office, on or before the 20th inst.
The highest or any tender not necessarily accepted.
By order,
C. F. PRESTON, Town Clerk.
Town Hall, Barrow-in-Furness, Nov. 1, 1888.

TO ADVERTISERS.

ADVERTISEMENTS for the next number of the JOURNAL must be received by Monday, 12 o'clock noon, to ensure insertion; but as the Advertisement sheet of the JOURNAL is sent to Press the first thing on Monday Morning, Advertisers will please bear in mind that Orders for Alterations in or Stoppages of PERMANENT Advertisements should be received Not Later than Two o'clock on SATURDAYS.

Undisplayed Advertisements—Situations Vacant or Wanted; Apparatus Wanted or for Sale; Contracts; Tenders; Public Notices, &c.—cost 3s. for the first six lines (about 42 words) or less; and 6d. for each additional line.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, NOVEMBER 13, 1888.

THE GAS INSTITUTE TRANSACTIONS FOR 1888.

THE issue of the volume containing the Transactions of The Gas Institute for 1888 is an event that calls for some comment, especially in view of the fact that the "transactions"—using the word in the ordinary meaning, as distinct from the special sense in which it is employed as the English equivalent for the French term *Compte Rendu*—of the Institute for the current year are not such as many of the members can regard with particular satisfaction. A melancholy interest attaches to the records of a moribund association, such as The Gas Institute has become since the meeting the doings at which constitute the bulk of the contents of the book before us. Before going into this part of the subject, however, it will only be fair to the authors of the published papers that notice should be taken of the volume as a contribution to the literature of the gas industry. It is commonly found that papers which are not very striking when read, look very well as afterwards printed and bound up with the appropriate

illustrations and diagrams. A mass of useful information is occasionally presented by collected communications upon technical matters, which can never have formed lively reading; while, on the other hand, the telling speech of the popular orator or humorist of the assembly, the delivery of which was marked by almost continuous applause or laughter from the delighted auditory, is often seen in all its shallowness when reduced to the cold page, and readers who well remember its effect upon themselves and others wonder how they could have been so moved. While we cannot be induced, by perusal of the contents of this volume of Transactions, to reverse the opinion formed at the time, that the papers, as a whole, fell distinctly below what might have been expected, we are free to admit that there are some among them that will be found most useful for reference by students of modern gas engineering. It is no part of our office to discriminate between these memoirs, and state our opinion respecting their comparative excellence. To do this, as the Council have to do it every year, is sometimes a rather invidious task; and we would rather that all the writers should be recompensed than that any of them should feel slighted. There is this satisfaction for the writer of a good paper that does not happen to be appreciated by its official judges—he has himself derived more good from the composition than can be conferred upon him by an outside agency. This is, after all, the great benefit of technical societies like The Gas Institute. Besides the educational value for students, of the contributions to literature which it may be the means of evoking from its members, there is the greater good done to the members themselves who prepare and discuss these communications. A man who belongs to a society of this kind, and never either prepares a paper or takes part in discussing papers prepared by his brethren in the industry, misses the greater part of the benefit of membership. We do not say that a member should be perpetually writing papers and speaking; for there are few who incline to this practice whose voice does not become hollow and lightly esteemed after a time. There is, of course, no possible laying down of rules as to how often or how much a professional man may write and speak without incurring the reproach of being more of a talker than a worker. Some men's experience is so much richer and wider than that of others, as their gifts of exposition are greater. One man may talk for an hour and only give an insight into the depth of his knowledge; another will "pump himself dry" in ten minutes. The only rule that can be regarded as generally applicable to these matters is that while no man should either take pen in hand or open his mouth in a meeting unless he has something to say, no man should refrain from expressing his opinions and giving his experience when the proper occasion arises. Reading, Lord Bacon has observed, makes a full man, writing an exact man, and reflection a wise man. It is good for a man to be in the way of becoming full, exact, and wise. Lord Beaconsfield said that the best incentive to learning all about a subject was to write a book upon it. This is only a restatement of the great Verulam's observation, and a confirmation of its truth. No man ever yet wrote a technical paper of any value without learning more about his subject than he knew before; and this is the true reward of such labour.

The volume of Gas Institute Transactions contains the two papers, by Dr. William Wallace and Mr. George Livesey respectively, which were taken as read at the meeting. All the other papers have been sufficiently discussed in the JOURNAL; but we must devote a little attention to these communications. The work of Dr. Wallace acquires additional interest as being the last production of the kind of its talented and respected author, whose recent death, noticed at greater length elsewhere, is a loss to the science of gas lighting that will not be easily made good. It deals with the effect of temperature upon the quality of gas produced from the same coal at different seasons of the year; and it shows, from an example that occurred in the author's practice as a gas analyst, that canal coal carbonized in the summer months possesses higher illuminating power than during the winter. The difference with a canal of very constant chemical composition, and yielding gas averaging 30-candle power, was as much as 2.77 candles between the monthly averages. The richer the gas, the greater would be the difference; while with gas made wholly from common coal, scarcely any such difference would be traceable. Although the author does not say so in as many words, his connection of the fall of temperature with the poverty of the gas, which he admits had to travel for a considerable distance

in the mains leading to the testing station, indicates with sufficient clearness that the illuminating power was brought down in consequence of this cold transit. To complete the paper, therefore, it would be necessary to know what was the nature and quantity of the condensation in the syphon-boxes for the different periods mentioned in the text.

Mr. George Livesey's paper on "Commissions" deals with an extremely unpleasant subject, but nevertheless one that must not be ignored. It cannot be said that the time that has elapsed since the Institute meeting has brought out anything to render this matter of less importance. In writing his paper, Mr. Livesey declares that he sought to place on record the protest of members of the Institute against the stigma that had been put upon them as a class; and it is rather a pity, if the protest was to be made at all, that it was not done in a more public way. For this, however, the author of the paper is not responsible. He did his best to state the matter clearly, and trace the evil to its source; and while recognizing the advisability of such a revision of the law as would make corruption less easy and excusable, Mr. Livesey laid stress upon the superior benefit of an elevation of moral tone which should render such offences impossible. It cannot be denied that a sharp division of opinion has prevailed respecting the policy of such papers. Certain members of the Institute thought that some such protest should be made public; while others, equally honest, regarded the evil in question as a mere manifestation of Original Sin, and as little amenable to preaching or protestation as that other evil to which the term "social" is prefixed as a special distinction. Others, again, may have wished to hush up the subject for more exclusively personal reasons. One cannot argue between all these conflicting views. As a matter of fact, the paper was not read; but here it is in the Transactions, for all to read who will.

A good deal of the volume is taken up with the record of the Bray incident, which cannot be pleasant reading, one would imagine, even to Mr. Bray himself, and is certainly a painful one for all well-wishers of the Institute. The record as it stands scarcely presents the state of affairs in such a way that they could be understood without extraneous knowledge. Thus, although in a foot-note to the record of the protest of Mr. Bray against the vote by which he was expelled from the Institute, it is remarked that the Council afterwards submitted to the injunction moved for by Mr. Bray reinstating him in his position as a member, there is no clear intimation of the other consequences of this action. An opportunity might have been found, had it been thought desirable, for stating that the bulk of the old Council resigned as the result of this proceeding; but what has been done is to print the list of those remaining in office up to the time of going to press with the book. This has rather a strange effect as it stands; for, whereas the list of officers for 1887-8 is of the usual imposing magnitude, with Vice-Presidents and Trustees in due order, the short list shows that all these dignified officials, and many more, had dropped out, without explaining how this happened—leaving this to be stated formally in next year's report of the Council. To return to the subject of the Transactions as a whole, however, one cannot help wondering whether this volume is destined to be the last of the series; or, if not, what the next will be like in point of quality. Although the contents of this one are not very striking, they might easily have been worse. It is to be hoped the future has something in store which will not cause us to regret the Transactions of 1888.

THE GAS AFFAIRS OF HALIFAX; AND MR. ELLIS LEVER'S PROCEEDINGS.

If affairs in connection with the Halifax gas scandal are not altogether stagnant, they are developing much more slowly than could be wished. When last mentioning the subject in these columns, a fortnight ago, we repeated what had been reported to us respecting the action expected to be taken by the Corporation of Halifax against Mr. E. G. Wrigley for the return of an alleged difference in value between the coal contracted for and that actually supplied by him to the Gas Department. No such action, so far as we can learn, has been entered upon up to the time of going to press. The Corporation have cancelled the contract with Mr. Wrigley, and have declined to receive any more of the canal; even ordering him, as we understand, to remove from their premises some unloaded railway waggons. This order was disregarded; and now we learn that Mr. Wrigley intends to continue to tender supplies. There must sooner or later be an end to this state of affairs; for substantial things like waggons of canal

cannot be bandied about indefinitely, like mere words and lawyers' letters. At present the impression received by an onlooker is that the parties are wasting time and imperilling reputation by all this manœuvring to escape from the responsibility of giving the first blow. With regard to the general situation, of which Mr. Wrigley's business with the Gas Department is but a portion, there is nothing satisfactory to be told. Mr. Alderman Riley does not seem to be prepared to do anything; and, from what can be gathered from the newspaper report of an important town's meeting, at which the Mayor attended, the local public are persuaded that all has not been as it should be in the administration of the gas-works. Of course, the whole matter is as yet in such an intangible shape that the facts, when they appear in the light, may well be altogether different from the imaginings of angry ratepayers. At present the townspeople firmly believe that they have been deceived in some way by those to whom they confided their interests; but how and to what extent nobody can say. There cannot be a much more uncomfortable feeling than this, either for a community or an individual. At the meeting referred to, the Mayor did not try to allay the prevalent excitement, but distinctly increased it by asserting that when the proper time comes for him to speak out he will have a monstrous tale to tell. "There has been very great wrong-doing," his Worship is reported to have said; and it is to be hoped the public mind will be pacified by a full disclosure at the earliest possible moment.

As Mr. Ellis Lever has confessed to being at the bottom of this Halifax affair, it may be convenient to refer here to his recent performances at other places, where he has essayed the same rôle of Champion of Purity and Disinterested Detective of Fraudulent Coal Contractors. He has withdrawn from the pursuit in the case of Salford, amid the painful jeers of the Town Councillors whom he has troubled for a long time past. Would it be stretching probability too far to connect his "strategic movement to the rear" with the inconvenient statements of Mr. James Ward respecting the intimate relations that formerly subsisted between Mr. Lever and Mr. Samuel Hunter? The true story of the notorious connection and parting between these two men would constitute an interesting commentary upon Mr. Lever's purity campaign. One wonders if it was from Mr. Hunter that Mr. Lever obtained that information respecting the corruptibility of gas managers and others, with the display of which he has lately been dazzling the public and getting admission to the books of Gas Committees who happened to be doing business with other coal contractors; as well as generally making famous use of it in the way of advertisement. It was in this way that Mr. Lever obtained the ear of the Leeds Gas Committee; but the result was not a success for himself. He was allowed to pick specimens of the coal supplied by the contractors to the Committee, and when these were tested by Mr. J. Paterson, F.C.S., of Warrington, and Mr. Fairley, of Leeds, the coal was found to be equal to sample. All his trouble has consequently gone to give a good repute to his trade rivals, and to diminish his own chances of getting upon the list of purveyors to the Leeds Corporation.

MEETING OF THE SOUTHERN DISTRICT GAS MANAGERS' ASSOCIATION.

The Southern District Gas Managers met on Thursday last, under the presidency of Mr. James L. Chapman, of Harrow, and had a very successful gathering. The society have changed their place of assembly from the Guildhall Tavern to the Hôtel Métropole, greatly to the satisfaction of the members, who have every reason to thank their energetic Honorary Secretary (Mr. Jas. W. Helps, of Croydon) for initiating the removal. Mr. Geo. Livesey read a paper in which he suggested a novel form of tank guide for gasholders, calculated to enable a holder to preserve its stability with only one tier of guide-rollers. The subject drew together a good audience, and several visitors known to be specially interested in it were present by invitation. Mr. Gadd, of Manchester, attended with models illustrative of his patent spiral system of guiding gasholders; and these attracted much attention. The paper itself was not very debateable; but there was a good discussion on the whole subject of the guide-framing of gasholders, which is undoubtedly one of the topics most interesting to gas engineers at the present time. Mr. W. E. Price, of Hampton Wick, also read a paper upon the obstacles that commonly stand in the way of increasing the popular use of gas, and the methods for overcoming them. It was a good paper, and served to introduce the author's very ingenious prepayment meter. All discussions

of this subject take the same line; and consequently the debate on Thursday in London might have been a continuation of that on Mr. Lewis's paper, which occupied the members of the Midland Association at their recent meeting, and a report of which appears elsewhere. With regard to the prepayment meter, it is possible, as hinted by the author, that a use may be found for this apparatus independently of that hitherto contemplated. The original purpose of these machines was to place gas at the command of the cottage class of consumers; but they may be found very useful for checking the supply of gas to cooking-stoves, which in most households are accused of making away with a good deal of gas. Servants are prone to be careless of the boiling-burners (which are large and apt to be extravagant), unless properly looked after. While the meter is silently recording the consumption without distinguishing that which is really useful from the waste, the householder has to wait until the end of the quarter before he can learn what has been going on. All this would be changed, however, if a prepayment meter were prefixed to the stove. It might then be found practicable to make the cook an allowance of money, and insist upon her paying for her own gas, which would be a long stride in the direction of economy.

THE LONDON COAL DUES AND THE METROPOLITAN BOARD OF WORKS.

THE Metropolitan Board of Works and the Corporation of the City of London have given the usual intimation of their intention to promote a Bill in Parliament next session for securing the renewal of the Coal and Wine Dues, with such modifications, limitations, and provisions as to the application of the revenue derivable from the dues as Parliament may think fit to impose. This action is, of course, the forlornest of forlorn hopes; indeed, there can be no hope about it, but the custodians of the public purse of the Metropolis probably feel called upon, as a matter of duty, to take every measure in their power to retain this money. The interest of the Metropolitan Board and of the City Corporation in the dues is not at all the same. Long before the matter can come under the consideration of Parliament, the Board will have ceased to exist, while the Corporation will be as lively as ever. The London County Council will have to deal with the taxation and expenditure of the Metropolis outside the City boundary; and it is preferable that they should start without any of that extraneous pecuniary resource that helped to render the old Board independent of, and consequently indifferent to the ratepayers. The Metropolitan Board are endeavouring to die with dignity; but they find it hard to do so amid their numerous trials. There was an unseemly dispute last Friday over the appointment of Chairman. Lord Magheramorne has held the office for seventeen years, and it has not been his fault if the latter days of the Board have come under a cloud. If only as a compliment to a veteran public servant, the re-election of his Lordship should have passed as a matter of course. It was not so, however; for a member of the Board, who did not find a seconder, took occasion to throw a good deal of "mud" at the Chairman. The performance was so gratuitous, and the justification offered so utterly insignificant, that it leaves the greater regret that it was not omitted, and so much the more peace and dignity secured for these latter days of the Board. With regard to the scandals that have come to light respecting the action of some officers and members of the body, it should be recorded that an interim report of the Royal Commission has been presented, and proceeds upon the lines long since accepted by public opinion. That some of the members and officials have acted unbecomingly, to say the least of it, is universally held to have been proved; but nobody suspects the great majority of members or officials of wrong-doing. It is possible that all the corruption that has existed in connection with Spring Gardens was not unearthed by the Royal Commission; but the work of exposure and purification has been fairly done, so far as it has gone. Nobody denies that, during the 32 years of its existence, the Board has done a vast amount of useful work; and if the cost has been heavy, there has been something to show for the money. It might have been wished that its career could have terminated without the disgrace that a few unworthy men have brought upon it; but the warning may prove worth its cost if it keeps the Board's more powerful successor from similar troubles. Having regard to the popular view of the Board at the present time, it would be wise for the retiring members to leave the County Council to other hands, by not offering themselves for election.

Water and Sanitary Affairs.

THE public have scarcely had time to appreciate the logic of the legal decision which, in effect, perpetuates the pollution of the Thames at Staines, when they are treated to another shock in connection with what is being done at Weybridge. Under the alarming head-line, "Proposal to Poison the Water 'Supply of London,'" our contemporary the *Morning Post* has published a letter from Sir Patrick Colquhoun which certainly demands attention. It is asserted that the parish authorities at Weybridge have initiated a scheme for disposing of their sewage by "collecting the raw material into 'tanks, and clarifying it by some chemical process.'" So far, well and good; but it is said that the effluent is to be poured into the river within a few hundred yards of the intakes of the five Water Companies which draw their supplies from the river for the purpose of serving the South-Western districts of the Metropolis. It seems incredible that it should be thought right for two small and comparatively obscure parishes, such as Weybridge and Shepperton, to enter upon a course so detrimental to the interests of millions of the inhabitants of London. We cannot doubt that means will be found to place a veto upon a scheme which, upon the face of it, is preposterous. In the first place, it is matter for the consideration of the Conservators, who receive an annual contribution of £5000 a year from the Water Companies, under certain guarantees for maintaining the purity of the water. It would be strange indeed if, after the activity displayed in abating the house-boat nuisance, it should be found necessary to submit to the wholesale method of pollution which the wise men of Weybridge have deliberately proposed to bring about—heedless of the peril and injury which their scheme would inflict on other people. Sir Patrick Colquhoun has done well in directing public attention to so scandalous a suggestion. There are, as he remarks, two other authorities besides the Conservators to be looked to as having some measure of responsibility in the matter—namely, the Government and the Water Companies. We cannot believe that the former will show any remissness in a matter of such vital interest and importance to the community. In regard to the Water Companies, it is certain that they will spare no effort and no expense in protecting their own interests—which, in this instance, are identical with those of their customers.

The annual report of the Local Government Board, which is unusually late this year in making its appearance, is remarkable for the amount of attention which it bestows on the subject of the Metropolitan Water Supply. The most critical part of the official record is that which relates to the extent of the resources at the command of the Companies for the purpose of supplying water to the districts they serve. This question is materially affected by the increase of the population on the outskirts of the Metropolis, and the consequent rapid addition to the customers of the Companies. The average population taking supplies last year amounted to very nearly 5,400,000 persons; and the growth goes on at a rate varying from 100,000 to 130,000 as the yearly increase of the population dependent on the Companies for their supply of water. The summer of last year (1887) was of a remarkable character, and calculated to put the existing provision to a severe test. In the week of maximum supply, the East London Company distributed on an average about 45 million gallons of water daily. Although this was the amount of the supply, the present Water Examiner, General Scott, does not consider it was the maximum demand; complaints being made that the supply was insufficient, the constant service being interfered with, and many of the houses being without cisterns for storage. Taking what he designates "the restricted maximum of 1887" as the basis of his calculation, General Scott proceeds to show that, allowing for increase of population, the East London Company would have to supply a maximum of 52 million gallons daily in 1892, presuming that year to be as dry as 1887. On this is founded another conclusion—namely, that under these circumstances the Company would require to obtain from some source or sources other than the Lea and their immense reservoirs, something like 22 million gallons per day. The other sources naturally evoked consist of the Thames and wells. If the quantity taken from the Thames is kept within the present statutory limit of 10 million gallons daily, as much as 12 million gallons will be required from the wells. The wells of the New River Company are said to yield about 14 million gallons per day; and General Scott declares that this

ought to be increased to 17 million gallons in 1892, should a drought then prevail. Adding this to the estimated requirements of the East London Company, it appears that the wells altogether must yield as much as 29 million gallons daily. We are told that it becomes "a matter for serious consideration" whether such a "supply can be obtained, and, if it is, whether the River Lea will not materially suffer by the interception of the springs which feed it." Hence we read: "On a general review of the whole circumstances, it seems evident that the question of the water supply of the North and East of London has entered a critical stage." We are further warned that an "authoritative examination" of the prospects of the population thus situated "cannot with safety be much longer delayed."

The year 1892 may not be a dry one; and the danger may thus be postponed. But if General Scott's anticipations are based on adequate data, there is reason for husbanding the present resources with the utmost care. It is to be regretted that the Southwark and Vauxhall Company have failed to find the lower greensand at Streatham. The remarks of General Scott extend to more than the East London and New River Companies. He does not appear to have any immediate anxiety as to the Thames, providing certain measures are adopted. As for the Kent wells, he thinks they should be carefully watched. The Local Government Board, in referring to the statements of General Scott, express an apprehension that it may become necessary before long to consider how the existing sources of supply in respect to at least some of the Metropolitan Companies "can be supplemented from other sources outside the watersheds of the Thames and the Lea." General Scott estimates that if 1892 proves a dry year, the maximum daily supply needed for London will then amount to 224 million gallons; reckoning for the whole of the area included in the territory of the Metropolitan Water Companies. It is certain that the demand for water in "Greater London" is growing enormously; and this circumstance is illustrated by the fact that, while the population of "London proper" has risen by less than 400,000 since 1881; that supplied by the Water Companies has risen by more than 800,000 in the same period. General Scott, desirous that the supply shall in every instance be both abundant and pure, evidently regrets the rejection of the Bill of the Grand Junction Company during the present year, and hopes for its revival, with such modifications as may render it acceptable. Satisfaction is expressed at the considerable advance made in the extension of the constant supply during 1887. Credit is given to the Companies for their voluntary action in this matter; the general rule being that neither the Local Authorities nor the inhabitants take the initiative. The action of the Companies leads to the belief that, on the whole, the constant supply is conducive to economy in the use of water. The practical value of Deacon's waste-water meters is recognized in relation to this part of the subject. As to finance, Mr. Allen Stoneham shows that the increase in the net water-rental of the Metropolitan Water Companies last year was £40,814; or more than in either of the two preceding years, and about the same as in 1881.

PRESENTATION TO MR. C. BIRD, OF ROCHESTER.—Last Friday week, Mr. C. Bird, who has been in the service of the Rochester Gas Company for a period of 48 years, was presented by the employees with his portrait (a life-size photograph), as a testimony of their esteem.

DEATH OF MR. E. THORMAN.—We regret to hear of the loss just sustained by Mr. E. H. Thorman, the Engineer and Manager of the West Ham Gas Company, in the death of his eldest son, Mr. E. Thorman, Engineer of the Malta and Mediterranean Gas Company, which occurred suddenly on Tuesday last, at Patras, Greece, where he was engaged in inspecting one of the Company's stations. The deceased was in his 48th year.

MR. ELLIS LEVER AND THE LEEDS GAS COAL CONTRACTS.—The Secretary of the Gas Department of the Leeds Corporation (Mr. James Lupton) has forwarded the following statement to the local papers:—"The Sub-Investigation Committee of the Gas Committee, along with Mr. Ellis Lever, Mr. J. Paterson (of Warrington), the Analyst appointed by him, and Mr. Fairley (of Leeds), attended, on the 7th inst., at the Meadow Lane Gas-Works, where the alleged inferior coal picked out by Mr. Lever was thoroughly tested in the presence of all the parties concerned. A joint report was drawn out by the two Analysts, showing that the coal was really equal to sample. Mr. Lever and all the gentlemen present expressed their complete satisfaction with the accuracy of the tests, and the perfect fairness with which the same had been conducted. Full reports will be published in due course, after the meeting of the Gas Committee."

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 858.)

THE past week has been rather a dull one for the Stock Exchange. There was no incident of special importance calculated to depress the markets; but they all seemed to go heavily, and nothing would rouse them. The condition of the Money Market, with gold still going out, also helped to keep down prices. The Gas Market, however, has naturally been anything but stagnant, and was especially active in the earlier part of the week. Dealings in Gaslight "A" have been extensive. We ventured last week to express the opinion that a recovery in price was not improbable; and the expectation has already been to some extent realized. An attempt was made to run the stock down still lower on Tuesday; and it was done at 244. But from that point it at once recovered; and, getting steadily firmer, was marked on Saturday at 249—the best price of the week. The quotation has risen 1½. During this time the "H" stock has not moved at all. The 4 per cent. debentures have receded 1; but even now they stand proportionately much higher than the other debenture stocks. This movement must be wholly independent of any electric agency. South Metropolitan "A" has been steady; but the "B" has come in for some hostility. Both these stocks stand high as compared with the other two Metropolitan Companies. Commercial old has fallen 2, for no other reason that we can imagine than that some nervous proprietor will insist upon selling his goods cheap. We suppose that if there be any one of the three Metropolitan Companies which has less than the others to fear from electricity, it is the Commercial. The new stock remains steady. There is very little of it; and it is dangerous stuff to "sell a bear" of. The same may be said, to an extent, of South Metropolitan "A." In fact neither of these stocks lends itself to artificial treatment. Suburban undertakings are very quiet, and show nothing to note but the continued firmness of Brentford. Foreigners have been rather weaker; European and Continental Union having slightly receded. Pará, however, has made an advance of ½. Water has been more than usually active—especially East London, which has risen 3. A good bit has been done in New River, at average figures. Slight advances are marked in Lambeth and Southwark.

The daily operations were: Brisk business in Gas on Monday. Gaslight "A" was better, and rose 1½. Pará also rose ½. Continental Union, partly paid, fell ½. Water was very firm; and Lambeth 7½ per cents. rose 1. On Tuesday Gas was again active. The bulk of the business was in Gaslight "A," which showed a tendency to relapse at one time, but recovered by the close. Quotations remained unchanged. Water again was firm; and East London rose 1. Gas was quieter on Wednesday. Nothing moved but European new, which was done very low, and fell ½. Water was unchanged. Thursday's business in Gas was much about the same as the day before. Gaslight "A" was steady; but South Metropolitan "B" looked weaker. In Water, East London rose 2 more. On Friday, Gas was rather quieter. Gaslight "A" continued steady; but South Metropolitan "B" receded 1½. Water was active, but unchanged. On Saturday, Gaslight "A" was firmer; the 4 per cent. debenture fell 1, and Commercial old and South Metropolitan "B" fell 2 each. Water was very quiet; and the only change was a rise of 1 in Southwark ordinary.

ELECTRIC LIGHTING MEMORANDA.

THE "ELECTRIC REVIEW" ON GAS DIRECTORS AND ELECTRIC LIGHTING—THE R. E. CROMPTON COMPANY, LIMITED—ELECTRIC LIGHTING PROPOSALS FOR BIRMINGHAM.

It is not often that we have to disagree with the editorial statements and comments of the *Electric Review*, the conductors of which journal are almost invariably fair in their remarks upon subjects connected with electric lighting. Very recently, however, they made a slip in this respect, probably through thoughtlessness, which occasionally overtakes the most careful and painstaking of editors. It is contained in an article entitled "A Sign of the Times," the drift of which may be understood clearly enough from the opening sentence, which states that "the progress which is being effected by electric light companies in every part of the country becomes more marked every day. Even in the South of England, where, with a few exceptions, gas monopoly has not been seriously shaken, there are signs of a great advance in the near future." This is all very well for a text; but when our esteemed contemporary goes on to observe in explanation of the fact that electric lighting is not yet in favour everywhere, that "gas companies are generally remarkably well represented on the different public boards, and hence the unwillingness of the latter, as a rule, to entertain the question of electric lighting," it is time to utter a word of protest. The sentence that follows the words last quoted runs: "It is satisfactory to note, however, in spite of the obstacles which an old-established and thriving monopoly is always enabled to put in the way of a comparatively struggling rival, the electric lighting movement is going ahead in a manner which can leave little doubt as to what its position will be in a decade or so hence." There are several weak points in these sentences; but, before dealing with them in any other way, we would ask whether the writer was aware that in the same issue of the paper which contained these statements there would appear the report of the result of the inquiries of the Exeter Town Council respecting the lighting of the streets of the city by electricity, and comparing the electricians' estimates with the cost of gas? It is very curious that

in one page of a technical journal we should find the occult influence of gas companies cited as the only obstacle to the rapid spread of electric lighting, and learn from another page of the same publication, "having regard to the large increase of cost as compared with that of gas," a Committee of the Town Council did not see their way to recommend the adoption of electric lighting for Exeter. Seeing that the difference in this case was as between £666 and £1486 per annum, we would ask the Editor of the *Electrical Review* to state whether the underhand influence of the local Gas Company was required in this instance. So long as examples of this kind continue to appear in its own pages, it is plain that our electrical contemporary need not go far to find reasons for the unwillingness of many public bodies to adopt electric lighting. We are prepared to admit that the uncalled-for imputation upon gas directors who may also be members of local authorities is a piece of thoughtlessness; but it is not less objectionable on that account. It is, moreover, an example of the manner in which the friends of electric lighting have blinded themselves and their followers ever since the beginning of their campaign. According to their showing, their misfortunes have never been their own fault. It is always "the gas interest" that has been to blame for their light being so dear and unsatisfactory. And yet the truth is so simple! That electric lighting is again becoming a favourite with the British public—or with some classes—is undeniable. The fact that the Edison and Swan Company earned last year a profit of £25,000 out of incandescent lamps alone is sufficient proof of the existence of a demand for these articles. The most that can be made out of this piece of evidence, however, does not affect the main point, which is that the electric light is a luxury for which some people are willing to pay. As a light *de luxe* there is some business in it; as a work-a-day light it cannot compete with gas at the ordinary British prices. If our electrical contemporary will confess the truth [of this way of stating the case, we will agree to his basing any amount of expectation and prophecy upon it. We think we have sufficiently shown, however, that to seriously ascribe the slow progress of electric lighting solely to the opposition, open or secret, of gas directors, is a ridiculous attempt to mislead.

The business of Messrs. R. E. Crompton and Co., electric light engineers of Chelmsford and London, is to be converted into a limited company. This is one of those things that might have been expected; for the firm have been prominent in connection with electric lighting from the beginning of the movement. Their business has been rapidly developed during the past three or four years—in short, since the collapse of the first electric lighting companies made an opening for manufacturing houses untrammelled by the unwieldy and useless paraphernalia of joint-stock concerns of the Lombard Street type. It is no part of our office to predict anything concerning the commercial fortunes of the new undertaking. All that need be remarked upon the subject here is that the formation of the Company is an interesting evidence of the revival of confidence in electric light engineering, as providing the basis of a profitable business, and that Mr. Crompton has for years been regarded as one of the best working authorities upon electric lighting matters. He has probably had as much experience in this line as any engineer in the kingdom.

The full text of the report of the General Purposes Committee of the Birmingham Town Council upon the question of the proposed Electric Lighting Order for Birmingham has been published. It begins with a recitation of the main provisions of the Electric Lighting Act, setting forth in clear language an abstract of the positions respectively occupied by local authorities and promoters of Electric Lighting Orders under the Act. Then the report descends to particulars, rehearsing how, two days after the Act was passed, Messrs. Arthur Chamberlain and George Hookham gave notice of their intention to apply for a Provisional Order for the supply of electricity within the borough of Birmingham. Ultimately the Draft Provisional Order, to which the consent of the Corporation was asked, was submitted; and it then appeared that the promoters only proposed to lay distributing mains in a few of the principal streets within two years, and the conditions regulating the compulsory supply appeared to be onerous as regarded the consumers. This first draft was accordingly objected to; whereupon a second was prepared and submitted, in which it was proposed to lay distributing mains in a considerable area in the centre of the town within three years. After looking into these proposals as thoroughly as time permitted, the Committee came to the conclusion that there was no need for hurry in the matter, and that it would be better to withhold the Corporation sanction from any Provisional Order for the present, or until the whole subject of electric lighting under the provisions of the Act of last session can be inquired into on behalf of the town authorities. Other promoters of electric lighting schemes have also appeared upon the scene; and the result of the Committee's deliberations upon the whole matter is that the public consideration of the Birmingham Electric Light and Power Order is temporarily deferred. It is not perhaps very complimentary to electrical science that the question of electric lighting for Birmingham should be declared to be unripe for settlement; but, on the other side, the Corporation need to be as careful just now how they accept any particular scheme as at any time during the past six or seven years.

The Society of Arts programme of business so far arranged for the first part of the coming session contains an intimation of a paper to be read, on "Standards of Light," by Mr. W. J. Dibdin, on the 19th prox.

THE LATE DR. WILLIAM WALLACE.

It is with sincere regret that we announce the death of Dr. William Wallace, F.R.S.E., of Glasgow, who was for so many years most intimately identified with the chemistry and physics of gas manufacture and gas lighting, and more especially known as the Gas Examiner for the City of Glasgow. The sad event occurred on Monday of last week, after an intermittent illness for at least two years. Until about a month before his decease, however, he was able to take a general superintendence of his business affairs; but his immediate acquaintances could scarcely help concluding that his end was fast approaching. He has left many attached friends to mourn his early removal from amongst them. He has also left a widow and a son and two daughters—the former, who bears his father's name, being an advocate in Edinburgh.

The deceased gentleman, who was 56 years of age, was a native of Edinburgh, but was educated chiefly in Glasgow. He early showed a marked inclination for the study of chemistry; and eventually became a student under Dr. Fred. Penny, Professor of Chemistry in Anderson's College, Glasgow. After completing his studies, he made a sojourn in Germany, where, at the University of Giessen, he had for two years studied under Justus von Liebig, and took his degree of Doctor of Philosophy (Ph.D.). On returning to Scotland, he was assistant for a number of years in the laboratory of Dr. Penny. He at this time gave a great amount of attention to the manufacture and purification of coal gas, practical illustrations of which were obtained by visits to the local gas-works. Dr. Wallace later on started on his own account as an Analytical and Consulting Chemist, in which capacity he had an extensive practice during the long period of 30 years. For nearly two-thirds of this time—from the year 1870—he and Mr. Robert R. Tatlock and Dr. John Clark were in partnership, carrying on such an important and extensive business of its kind as had never before been known in Scotland. Dr. Wallace continued to give special attention to the study of coal gas—its analysis, its manufacture, purification, examination photometrically, economic combustion, &c.; and in this branch of technology he eventually became one of the leading authorities in the United Kingdom. His position as an expert in gas matters was early recognized by the Magistrates of Glasgow after the gas supply of the city passed into the hands of the Corporation under the provisions of the Glasgow Gas Act of 1869. In the following year they appointed him Gas Examiner for the city; and in this capacity he had to conduct weekly testings at several stations. He retained this office up till his death. Latterly he was also Gas Examiner for the burgh of Paisley; and he had likewise made professional examinations of gas in London and other English as well as Scottish towns.

MR. ELLIS LEVER AND THE SALFORD GAS UNDERTAKING.—At a meeting of the Salford Town Council on Friday last, Mr. Alderman A. L. Dickens, who was unanimously re-elected Mayor of the borough for the ensuing year, read a letter he had received from the Solicitors of Mr. Ellis Lever, withdrawing his proposal to furnish evidence of frauds in the Gas Department to a Committee of the Council, on the ground mainly that, as the Mayor had expressed his determination to have a shorthand writer present, such information as he gave might be used as the basis of further litigation against him.

GAS-CONTAMINATED WELLS AT GOSPORT.—In reference to the paragraph on this subject in last week's JOURNAL (which was based on a communication to the London papers by a local correspondent), Mr. Geo. B. Irons, the Manager of the Gosport Gas Company, writes to say that the statement as to the closing of the wells owing to contamination was erroneous; the fact being that an auxiliary supply is being laid on to the Royal Clarence Yard by the local Water Company, and the Gas Company are at the same time taking up their old mains, which have been in use for 40 years, and replacing them by larger ones.

SOCIETY OF ENGINEERS.—At a meeting of this Society, held at the Westminster Town Hall, on Monday, the 5th of November—Mr. A. T. Walmisley, the President, in the chair—a paper was read by Mr. H. Ross-Hooper on "The Practice of Foundry Work." The author first briefly compared the particular qualities and properties of pig iron, with the view of determining the varieties which are best adapted to the requirements of the different kinds of castings made; and showed how the nature of cast iron depends not only upon the amount of carbon it contains, but upon the conditions under which this carbon exists. He then proceeded to illustrate how the failing of portions of a cast-iron structure may be traced to a want of knowledge in the way the lines of crystallization flow on the cooling of the metal, and mentioning the weak points to be guarded against in the designing of cast-iron work. After explaining the operations of chill casting, malleable cast iron, and the system of moulding known as "Jobson's Blocks," whereby sand moulds of thin delicate patterns can be made by ordinary labourers, the author mentioned the different modes adopted for casting according to the forms and requirements of the various articles to be produced, and how sound results can only be obtained by careful attention to the feeding of the metal to supply the shrinkage and drawing away which must inevitably occur on the cooling of the metal. The cupola, its construction, and advantages over other types of furnaces, and the manner of charging it, together with the appliances necessary to a foundry were duly considered. The author then dealt with the examination of cast ironwork; and finally discussed the tests usually applied, and the general strength of cast iron.

A GASHOLDER DEBATE AT THE SOUTHERN DISTRICT MEETING.

THE members of the Southern District Association of Gas Engineers and Managers had a very good meeting on Thursday last, when assembling for the first time in the Whitehall Rooms of the Hôtel Métropole, they had brought under their notice two papers, either of which would have constituted sufficient *pabulum* for an ordinary gathering. The first was the contribution by Mr. George Livesey; and the second by Mr. W. E. Price, of Hampton Wick. Mr. Price's paper was very good, and his introduction of his extremely ingenious prepayment meter was particularly well received. The chief attraction, however, was Mr. Livesey's paper upon gasholders without upper guide-framing, and this not only on account of the author's eminence, but also because of the position at present occupied by the subject in the minds of gas engineers. As it appeared, moreover, the energetic Honorary Secretary (Mr. J. W. Helps, of Croydon) had taken exceptional measures for organizing a good debate upon the papers of the day. Both papers had been printed and circulated some days beforehand, in order that members attending the meeting might be well posted respecting the points likely to arouse discussion; and a full attendance of specialists who were known to be interested in the subject of Mr. Livesey's paper was arranged for. The result was the best debate upon the general question of gasholder guiding that has been recorded anywhere. Mr. Gadd, of Manchester, attended with his models of spiral tank-guided holders; showing the invention as applied to single-lift and telescopic vessels. The models were carefully, though not elaborately, constructed; but besides demonstrating the fact that holders built according to Mr. Gadd's principle are stable, they also showed that nothing like a real inference, applicable to the working of full-sized holders, can be drawn from such miniature imitations. Mr. Livesey had also intended to illustrate his ideas by means of a model, but it could not be completed in time. He had, however, provided himself with small-scale specimens of the tank guides described and illustrated in his paper, which served the purpose of showing how a holder so guided would work up and down. Photographs of the Rotherhithe holder, as enlarged by the addition of a third lift without raising the guide-framing, were also exhibited to the members at the meeting. Altogether, what with Mr. Livesey's paper and remarks, and the observations of the visitors interested in the subject—among whom, as Mr. Gadd has already been named, we must also specify Mr. H. Woodall (the President of The Gas Institute), Mr. S. Cutler, Mr. F. S. Cripps, and Mr. W. H. Y. Webber—the members of the Southern District Association must have felt that the subject of gasholder guiding was being pretty well thrashed out before them, especially as most of the speakers referred to articles and other communications published in the JOURNAL for the further exemplification of their views. The long debate was characterized by the greatest good humour; and the speakers, one and all, manifested the most praiseworthy disinclination to dogmatize respecting views held by themselves and others. To say that the discussion threw much additional light upon the subject, or either cleared away or confirmed any doubts which members of conservative tendencies may have felt after inspecting Mr. Livesey's pattern guides and Mr. Gadd's models, would be claiming too much for it. In effect, the net result of the afternoon's talk was to leave the essential points of the question of external guide-framing pretty much as they were, with this difference: The objects of the suggestion, and the most obvious objections to it, were more clearly defined; and Mr. Livesey showed how, if Mr. Gadd's principle is admissible, the same result can be attained by simpler means. It is not denied that Mr. Livesey was put upon the scent by Mr. Gadd, any more than that Mr. Gadd was directed to the study of the subject by the stress laid by Mr. Webber upon the bottom guiding of holders. Mr. Gadd has undoubtedly shown how Mr. Webber's aim may be secured; and Mr. Livesey in turn demonstrates that the effect of Mr. Gadd's long spirals, going a long way round the tank, may be gained, if it is deemed desirable, by tank guides so like these ordinarily in use that they may be fixed in the same way and adjusted by a single plumbing operation for each. Somebody else may, and probably will, come forward in due time with a scheme for doing the same thing in a different and, in his own opinion, superior way of that of either Mr. Gadd or Mr. Livesey. There is no finality in a matter of methods, such as this is. The question of the possibility of safely attempting an experiment remains untried. Mr. Livesey flatly says that, although he can see how the thing may be done, he is by no means favourably disposed to doing it; and here the matter rests for the present.

Among the points that came into prominence in the course of the discussion, one of the most important, in the practical sense, was that of the fundamental difference, in their effect in transmitting strains, between tangential and radial guide-rollers. The radial roller tends directly to cripple the curb to which it is attached; whereas the tangential form, as the name implies, brings the strain to bear tangentially to the curve of the curb—that is to say, along its line of greatest strength. The importance of this consideration appears very conspicuously in connection with a remark of Mr. Cutler. He said that he had never seen a proper bottom curb; meaning that these parts of a gasholder are never made sufficiently rigid. There is, however, a difficulty in making a bottom curb really strong, because of the absence of room for a horizontal member, of any depth, corresponding in effect to the first row of plates of the crown. By placing the bottom rollers tangentially, the crippling effect which the shallow bottom curb is

so ill-adapted to withstand is avoided, and the curb is as though doubled in strength and rigidity to resist deformation. If only this comparatively minor matter is properly attended to, the discussion of this at present theoretical subject will not have been without some practical fruit.

WATER ACTS FOR 1888.

THE following Acts relating to the supply of water by Companies were passed during the last session of Parliament.

The Frodsham Gas and Water Act enables the Frodsham (Cheshire) Gas Company to undertake water supply, with a special share capital of £25,000, and power to borrow to one-fourth of the amount called up. The water-works include a well and bore-hole and pumping station in Frodsham parish, a high and a low service reservoir, and the necessary pipe-lines. The land required is to be taken within seven years; and the works are to be completed in eight years. The rates for domestic supply range from 10 to 8 per cent. upon rental, with an extra third for the high-level service. The Helston and Porthleven Water Act incorporates a Company, with a share capital of £8000, and power to borrow £2000, for the supply of a district round the town of Helston, Cornwall. It is provided that, if any parish included in the district remains without a supply of water in accordance with the terms of the Act for seven years, the powers of the Company in respect of such parish shall cease. The authorized works comprise an impounding reservoir upon the Tregathenan stream, a service reservoir in Wendron parish, and the necessary pipe-lines. The land required compulsorily by the Company is to be acquired within three years; and the works must be executed within five years. Certain provisions are made for the protection of Baron Churston and his tenants. The supply is to be constant under pressure. The rates for a domestic supply are to be 7½ per cent. upon property above £20 annual rateable value, with extras as usual. Water supplied by meter is to be charged for at the rate of 1s. 6d. per 1000 gallons. The Limsfield and Oxted Water Act incorporates a Company formed in 1886, and at the time of the passing of the Act having a capital of £4500, and owing £1500. The capital of the incorporated Company is fixed at £14,000, whereof £10,000 is additional capital. There are borrowing powers to the extent of £1500 in respect of the original capital, inclusive of the amount already raised; and £2500 may be borrowed on the additional capital. The works are to be extended by the construction of two reservoirs and several lines of main, to be completed within five years. The land held on grant by the limited Company is to be purchased within three years. Rates for domestic supply are to range from 10 to 7½ per cent., with 9 per cent. for inns. The supply is to be constant under pressure. An agreement between Mr. G. W. G. Leveson Gower and the Company for the lease of certain land is scheduled in the Act. The South Lincolnshire Fen Water Act incorporates a Company with a capital of £50,000, and power to borrow £15,000, for the supply of a district in the fens of the parts of Kesteven and Holland, Lincolnshire, with the provision that the statutory rights are to be forfeited in the case of any parish not supplied within five years. The water-works are to comprise a well and pumping station, and the necessary auxiliary works; the land to be acquired within three years, and the works to be finished within five years. An agreement relating to the purchase on behalf of the Company of certain lands, together with a bore-hole, for a fixed sum and a rent-charge is set out as a schedule to the Act. The supply is to be constant under pressure; and the rates for domestic service vary from 7½ to 5 per cent. upon rateable value. The Uckfield Water Act incorporates a Company with a capital of £5000, and power to borrow £1250. The works include a well and pumping station in the parish of Uckfield, a service reservoir in the parish of Buxted, and the usual subsidiary works, to be completed within five years. The rates for household supplies range from 8½ to 6 per cent.

The Barnstaple Water-Works Act enables the Barnstaple Water Company to raise £18,000 under the auction clauses, with power to borrow to one-fourth of the amount called up. The limits of supply are extended; and one-fifth extra to their usual rates is permitted for supplies at high levels. New works, comprising pumps, service reservoirs, and pipe-lines are sanctioned, subject to any claims for compensation from riparian owners below the Company's intake on the River Yeo. The new works are to be completed within seven years. The Act also enables the Company to make regulations for preventing waste of water, and to sell water by meter. The Brymbo Water Act authorizes the Company to construct additional water-works, including an impounding reservoir upon the Pen Dinas stream, and an intake from a lake, the sporting rights upon which are reserved. Compensation water is to be discharged down the bed of the impounded brook, under penalty of £5 per day for default. The works are to be completed within seven years. The Company are empowered to raise £15,000 of additional capital under the auction clauses, with power to borrow £3750. The power to sell water in bulk, frame regulations for preventing waste, and other facilities are also conferred by the Act. The Bristol Water-Works Act enables the Company to raise £240,000 additional capital under the auction clauses, and to borrow £80,000 in respect of capital authorized by an Act of 1882, as well as £60,000 in respect of the new capital. The Company's works are to be enlarged by the construction of pipe-lines, intended to collect, under various restrictions, the water of certain springs, and pumps for lifting the same into the Company's existing reservoir. The works are to be completed within seven years. The

district of supply is enlarged. The Folkestone Water Act extends the Company's limits of supply, and enables them to raise £20,500 of new capital under the auction clauses, with power to borrow £19,875 in respect of their original and to one-fourth of the amount of their new capital as called up. It is provided that, from and after the passing of the Act, the Company shall allow a sufficient supply of pure water for the domestic use of the inhabitants of any house within their limits, at a pressure sufficient to reach the top storey of every house, and so that every such house shall be supplied with water for at least five hours daily; and after July, 1889, the inhabitants of a district of Folkestone which is specially defined upon a map are to have a sufficient supply of pure water constantly laid on at such a pressure as will make the water rise 130 feet above Ordnance datum. The Fylde Water-Works Act repeals parts of older Acts applying to the Company, more especially with regard to compensation water, providing for the satisfaction of certain estates. Additional land is to be acquired. The Kent Water-Works Act extends the Company's limits of supply, sanctions new works, and enables the Company to raise £100,000 by the issue of debenture stock, to be offered for public sale, and to bear interest at not exceeding $4\frac{1}{2}$ per cent. per annum. The Staffordshire Potteries Water-Works Act extends the Company's limits of supply, enables them to raise £180,000 under the auction clauses, with power to borrow to one-third of the amount as issued, and sanctions new works, comprising pumping stations and reservoirs, to be completed within ten years. The Corporation of Longton are protected by the devotion to their particular service of a special main from the Meir reservoir. The West Surrey Water Act enables the Company to raise £40,000 under the auction clauses, and to borrow to one-fourth part of the amount as issued. New works are sanctioned, including an additional intake from the River Thames, from which the Company are authorized to draw 3 million gallons per day. Water may be sold in bulk at the rate of 9d. per 1000 gallons, provided that the demand does not interfere with the domestic supply. The London Sea Water Supply Act extends to July 18, 1890, the statutory powers of the Company for executing works in certain parishes named.

MESSRS. G. W. STEVENSON AND SON, of 38, Parliament Street, have intimated to their clients that, owing to Mr. Stevenson's very serious illness necessitating his entire relinquishment of active work (to which reference has already been made in our columns), the practice will be continued by Mr. E. Herbert Stevenson, who, having been associated with his father for the past eighteen years, is intimately acquainted with all its details.

It is announced that the registered offices of the "Beck" Gas-Engine Company are about to be removed from Newcastle, to a good business centre in London. This step is being taken, it is understood, with a view to suit the convenience of the Directors. The Company have just dispatched to the Southwark and Vauxhall Water-Works Company a 12-horse power engine, to be used in connection with an electric light installation.

In financial circles, a Buenos Ayres Water-Works Loan has been spoken of for some time; and rumour has placed the amount as high as £10,000,000. This, however, seemed an exaggeration, says the *Standard*, even for the insatiable River Plate communities. But it is now reported that the issue of the capital of a Buenos Ayres Water-Works and Drainage Company is decided upon; and that it will be made at an early date by Messrs. Baring Bros. and Co., to the extent of £8,000,000.

THE Royal Commissioners appointed to inquire into the proceedings of the Metropolitan Board of Works have made an interim report, which has just been presented to Parliament. They have submitted the conclusions at which they have arrived on the evidence laid before them; leaving further inquiry to be made later on, should it be deemed expedient. In concluding their report they express an opinion that it might have a wholesome effect if it were distinctly made a criminal offence to offer to any member or official of a public body any kind of payment, fee, or reward, having any relation to the affairs of the body of which he was such member or official, and also to make the person accepting such payment, fee, or reward amenable to the criminal law. They think that the provisions of the Corrupt Practices Act would afford some very useful suggestions in the framing of such an enactment.

We have received a copy of the "American Gas Engineer and Superintendent's Handbook" from the author, Mr. W. Mooney, of New York. It may be shortly described as an American "New-bigger;" the compiler having, in the selection and arrangement of his material, followed generally the plan adopted by his English predecessor, and even gone so far as to copy him almost exactly in the outward garb in which that material is presented. Mr. Mooney admits, in his preface, that such a book as the one he has produced must, of necessity, be made up in a great measure of the writings of others; and this is fully borne out by a glance at the contents. At the same time, it is not entirely devoid of original matter. Commencing with the composition of American coals and the nature of the residual products of carbonization, the author proceeds to describe the appliances used in the manufacture, testing, storage, distribution, and consumption of gas; the test being illustrated by a number of diagrams. The remainder of the book consists of reference tables, useful rules, and other data for the guidance of gas managers; and concludes with an epitome of chemistry.

Technical Record.

SOUTHERN DISTRICT ASSOCIATION OF GAS ENGINEERS AND MANAGERS.

The Quarterly Meeting of this Association was held on Thursday last, in the Whitehall Rooms of the Hôtel Métropole. The PRESIDENT (Mr. J. L. Chapman, Assoc. M. Inst. C.E.) occupied the chair; and the attendance of members and friends was larger than usual, owing to the announcement that the papers to be read were on subjects which are now receiving so much attention in gas engineering circles.

The SECRETARY (Mr. J. W. Helps, of Croydon) read the minutes of the preceding meeting, held at St. Albans in May last, and they were confirmed.

ELECTION OF OFFICE-BEARERS.

The PRESIDENT said that his term of office was closing; and, according to the *agenda*, the proposition had now to be laid before the members to elect a new President. The Committee had—he thought wisely—decided to nominate Mr. John Somerville for the position, as he had done a great deal in promoting the welfare of the Association. He hoped the proposition, which he moved, would be received in the most cordial manner.

Mr. JABEZ CHURCH (London) seconded the motion, which was carried with acclamation.

The PRESIDENT said that, according to the rules, two members of the Committee would retire at this meeting. By some error at the last general meeting, Mr. Helps having kindly taken the position of Secretary, they omitted to elect another member in his place, so that there were three gentlemen to elect on the present occasion. Those who had consented to take office at the Committee's request were Messrs. A. Mead (Chelmsford), S. Durkin (Southampton), and W. E. Price (Hampton Wick).

Mr. W. H. H. BROADBERRY (Tottenham) proposed the election of the gentlemen mentioned by the President.

Mr. C. GANDON (Lower Sydenham) seconded the motion, which was agreed to.

The other officers of the Association—the Treasurer (Mr. A. H. Wood, of Hastings), the Secretary (Mr. J. W. Helps), and the Auditors (Messrs. C. Farrand and E. Price, of London)—were all re-elected.

ELECTION OF NEW MEMBER.

Mr. John Methven, of the Nine Elms Station of The Gaslight and Coke Company, was elected a member of the Association.

CHANGE OF MEETING-PLACE.

The PRESIDENT said that, before he proceeded with the other business on the *agenda*, he should like to remark that it was through the energy of their Secretary that they were able to meet together in that room, which he thought was better than the one in which they had hitherto met. The room had been obtained on terms almost as good as those on which they had the room in the City; and he (the President) hoped the members would agree that the Secretary had done wisely in bringing the Association there. The next thing to occupy their attention would be the papers. They were very much indebted to the gentlemen who had come forward to help them; and he hoped they would have an interesting meeting in every respect. Mr. Livesey had always been their friend, at their beck and call; and they had to thank him very much for bringing before the Association the subject which, of all others, was at the present time being so much discussed by gas engineers.

READING OF PAPERS.

The two papers prepared for reading and discussion were: (1) "The Guide-Framing of Gasholders: How and How Far may it be Dispensed With?" by Mr. George Livesey; and (2) "Some Hindrances to the Sale of Gas," by Mr. W. E. Price. These appear in full elsewhere to-day; but, consequent on pressure on our space, the report of the discussions is unavoidably held over until next week.

At the conclusion of the discussion on the last-named paper, the proceedings were wound up by proposing the following

VOTES OF THANKS.

The PRESIDENT said that before the meeting separated, he thought they should pass a cordial vote of thanks to Mr. Livesey and Mr. Price for the interesting papers they had kindly contributed. They ought to include in the vote Mr. Gadd, for bringing to the meeting models of his arrangement for guiding gasholders, and also Mr. Cripps and Mr. Cutler, who had taken part in the discussion.

The proposal was heartily acquiesced in.

Mr. BROADBERRY said there was one more vote they had to pass, and that was to their retiring President for the way in which he had conducted the affairs of the Association during his year of office. He had much pleasure in making the proposition.

The motion was agreed to amid great applause.

The PRESIDENT briefly thanked the members for their hearty vote. He hoped that they would extend to his successor in the chair the same courtesy that had been shown to him.

This concluded the business of the meeting, and the members afterwards took tea together.

MIDLAND ASSOCIATION OF GAS MANAGERS.

THE DISCUSSION ON MR. LEWIS'S PAPER.

Last week we gave an account of the general proceedings at the recent meeting of the Midland Association; reserving till to-day the report of the discussion that took place on the paper presented at the previous meeting by Mr. Lewis, entitled "The Competition of Petroleum with Gas for Lighting Purposes."

THE PRESIDENT: I regret that at the Bath meeting we were obliged to take Mr. Lewis's paper as read, and to defer discussion upon it.* The delay, however, has given you the opportunity so often desired of seeing the paper in print before it was read; so that you should now be better able to discuss it. The paper went a little beyond its title, and for the purpose of discussion may be divided into two parts—First, the subject conveyed by the title; and, secondly, the policy of gas companies or gas undertakings towards their consumers.

MR. J. S. CRANMER (Stratford-upon-Avon): Our thanks are due to Mr. Lewis for bringing the subject before the meeting at Bath; and I am sorry we could not discuss the paper then, although possibly during the interval we may have had time to digest it, and to bring our experience to bear upon it. Last week, through the kindness of the Editor of the JOURNAL, a letter was inserted [see *ante*, p. 636] asking for information on this subject. The Gas Committee of my Corporation are very anxious to assist me in endeavouring to drive out what I may term our strongest competitor—petroleum oil; and they requested me to obtain all the information I could on the subject. I forwarded the letter I have mentioned to the JOURNAL; but I am sorry to find there are no replies this week. The reason why, I am unable to say. Whether it is from the lack of information, or from that natural—I would not say timidity—but modesty on the part of managers in general in regard to furnishing information, I cannot say. Mr. Lewis has very kindly given me information; and I trust I may yet gain some from other sources. It appears to me that the question of supplying gas to small consumers is one that should be taken into consideration, not only by gas managers, but by corporations and gas companies. There is a wide field open in this direction; and it is only by determining the best means of dealing with the matter, that we shall be able to drive out our competitor. In my case, we have been repeatedly asked by people who would be small consumers, if we would supply them with gas. Under our present rules, we are unable to do so. If we afforded them a supply, the difficulty at the end of three months would be to get payment. Now, I do not see any reason why we should not adopt the same plan as is carried out by those who go out selling oil in small quantities, and who collect the money weekly. One difficulty, I see, is the provision of gas-fittings for these small customers. In the majority of cases they are not in a position to pay even 20s. for fitting up a house. The owner of the property will not do it; and the result is we are losing consumers, who, I am confident, would pay us equally well as some other classes. A little more trouble might be caused to the manager; but I contend these customers would pay us equally as well as some of the larger consumers. If any plan could be adopted for providing gas-fittings and charging a small rent for them, we might be able to provide alike for the cottager and artisan at quite as cheap a rate as the oil-man does at the present time; and we should all reap a benefit by so doing. At present I have not done anything beyond making inquiries; but if these inquiries lead to satisfactory results, I shall be pleased to make them known to the Association at some future time.

MR. P. SIMPSON (Rugby): I cannot give any information on the question of petroleum *v.* gas; but I have heard it stated by other managers that the bad debts amounted to such a considerable sum for the gas consumed by small customers, that it was one great drawback to supplying them. I think, with Mr. Cranmer, that it would be a great benefit to all gas companies if they could get into the way of collecting the accounts from small consumers more frequently. I have in several instances had to cut off the supply to small consumers, because in the winter quarter it comes to rather a considerable amount, and there is not that forethought which perhaps was more prevalent in olden times of laying up for a rainy day. As a rule, the working population live from week to week; and to take the amount of a quarter's gas account out of a week's wages might sometimes cause a difficulty in the family. If we could collect the money more frequently, it would be a help in supplying small consumers. In my own case I supply 889 cottages, and 630 shops and large houses—a total of 1519. I have taken a district of two streets, which contain about 400 cottages, of which about 156 use gas; the average consumption in 1887 being 9314 cubic feet for each cottage. The cottages in these two streets are not built as many are. They are all freeholds; but there are very different classes of cottages in the same street. We have numbers of cookers in use in these streets; and there are differences of degree in the consumption, which may make the average consumption appear large. Taking the last five years, the average annual consumption of the 889 cottages was 8,389,000 cubic feet; and of the 630 shops and large houses, 26,463,000 cubic feet. This gives an annual consumption of 42,000 feet for the larger consumers. Taking the five years, I have had for these 889 cottages, on an average, bad debts amounting to £3 13s. 9d. per annum, and for the 630 shops and large houses an average of £12 0s. 6d. This gives for the cottages bad debts averaging 0·09d. per 1000 cubic

feet; and for the larger consumers, 0·11d. Now, as a compensation against this loss by bad debts, the price is 3s. 2d. per 1000 cubic feet, with 2d. discount if paid in a given time. In the past five years, the average amount received per annum from those who have lost their discount is £29 12s.; so that, after deducting from this the bad debts (£15 14s. 3d.), there was still a balance left of £13 17s. 9d. above what would be received if all had paid 3s. per 1000. I may say that a great drawback to cottagers having a supply of gas is the requirement in some instances of a deposit and a charge for laying the service-pipe. At Rugby we do not ask for a deposit; and we lay the service within the house. In my opinion, small consumers would not, as a rule, pay deposits. I have never tried to obtain them; and do not think I should be likely to succeed if I did. We collect our accounts every quarter. The accounts are made up (say) to Sept. 30. The bills are then delivered; and every customer is seen twice before the end of October. This gives them the benefit of the discount if they pay; and the second time the collector goes round, he takes a considerable amount of money. After the second month, unless the customers pay, the supply is discontinued; and they are put into Court. I have contemplated bringing before my Board the question of more frequent collections.

MR. MILLARD (Hinckley): I am strongly of opinion it does not pay to foster a consumption among small consumers, especially where, as in Mr. Simpson's case, you put in the service free, and allow the consumers to have meters without charging hire. Even if you take the interest on the outlay at the small figure of 5 per cent., there is also the cost of collection, and other matters. Mr. Simpson says that he has an average consumption in the case of his cottage consumers of more than 9000 cubic feet. In my own case at Middlesbrough, before I went to Hinckley, the consumption was about 8900 cubic feet. It really does not pay; but with the object of broadening the basis of the gas-works, we did try to foster consumption in this direction, hoping that we should also obtain increased consumption by the use of gas-cookers. We arranged in all cases where landlords would put in the internal pipes, to fix the service-pipe and meter without any charge. A good many of them did so; and it was always found that these cottages let the best. Of course, there is a residuum of population of a migratory character who it would not be worth while having as gas consumers.

THE PRESIDENT: Do you include the consumption by cookers in the figures you have given?

MR. MILLARD: Yes. There were usually two lights in the cottages I referred to. In the end, the landlords began to make recesses for the cookers; and it saved the expense of a range in the back places.

MR. HUNT: I was glad to hear Mr. Millard's remarks, because it has appeared to me that, in discussions upon this subject, it has too frequently been assumed to be the special mission of gas suppliers to oust all competitors, without any regard to cost. Gas supply ought surely to be on the same footing as any other business, in respect to which blame would attach to any one carrying it on at a loss; and the first thing to determine is whether or not the new business we are seeking to acquire is likely to prove remunerative. If it is not, it cannot matter whether oil or candles be used, or even the electric light. I remember that, in the time of the Companies, it was said in Birmingham of a certain class of consumers that it would pay to put in the service-pipe, supply and fix the meter, and then never go near the premises again—that is to say, the consumption was insufficient to cover the cost of attendance upon the meter and collection, to say nothing of depreciation and interest on cost of service-pipe and meter. Without going so far as this, it is evident from the smallness of consumption in cottage property generally, that caution is necessary in extending the business in this direction. It may be quite true that it cannot be said of any single consumer, "This one pays; and that one does not," in the sense of supporting a gas undertaking; but having regard to the class, rather than the individual, we can at once recognize the difficulty that would be experienced with a gas undertaking whose consumers were solely composed of small cottage occupiers, having say two lights apiece. It must be apparent that an average consumption of 4000 to 5000 cubic feet per annum could not be supplied at so cheap a rate as an average consumption of say 20,000 or 30,000 feet; other conditions being the same. Moreover, in the migratory character of a large portion of the smaller occupiers, especially in the larger towns, there is an element of insecurity, which can only be met by a system of very short collection, or prepayment by meter or otherwise. In this respect Mr. Simpson's plan appears to have been very successful, although he is evidently more favourably situated than are many others. As regards the extension of gas consumption generally, I feel convinced that Mr. Simpson is upon the right track. Some years ago I had occasion to make enquiries upon the subject, and procured returns from various towns—Mr. Simpson's among the number. I was greatly impressed by the proportion of consumers to population, and consumption per head of the population; for these bore a very close relation to the policy adopted towards the consumers. Where restrictions were in full force—the deposit and guarantee system in full swing, there the consumption was least. On the other hand, where a liberal policy was indicated by the information afforded by the returns, there the use of gas was proved to have widely extended limits. In this way the consumption per head of population was shown to be actually less in the case of a large manufacturing town than in that of a

* Mr. Lewis's paper was given in the JOURNAL for May 22 last (p. 913).

comparatively small town having a semi-rural population. When looking at a balance-sheet, it is too often assumed that a small amount for bad debts is an indication of good management. I am not sure that it may not sometimes be the reverse. At all events it is most probable that the growth of business would in many cases be more satisfactory if a more liberal policy were allowed to prevail.

Mr. H. TAPLAY (Stoke-upon-Trent): I can endorse Mr. Hunt's remarks. In our Potteries district, we have a population similar to his own—a migratory one. One inducement we gave to this population to use gas was to do away with meter-rents and fix meters free. This led to about 50 new consumers with a consumption of 400,000 or 500,000 cubic feet a year; but our net loss at the present time will be about £500 a year in meter-rents.

Mr. NORTH: That means you dropped your meter-rents all round?

Mr. TAPLAY: Yes.

Mr. J. A. HARRIS (Wigston): With regard to the use of petroleum for heating purposes, I may remark that at Wigston experiments are being tried at one or two shoe factories to heat irons by this means. The only drawback is that the irons are blacked. I should like to ask if there is any case where heating by petroleum is carried out successfully. With regard to the supply of gas to cottages, in my opinion we need caution. If a genuine good tenant will take gas, we ought to make it as easy as possible in the first place to start the consumption, by laying the service-pipe and fixing the meter free of cost. In the case of cottages not already fitted up, it would also be to our advantage to do the work at a small margin of profit. The start is the principal thing. If we know people are likely to be sure tenants of a cottage, and gas-fittings are not fixed in it, it might be advisable for some one from the gas-works to see the landlord. There are tenants who would be willing to pay a penny a week more if the landlords provided the gas-fittings. In a new district, where there is a population of about 2000, we have experienced more difficulty than in all the other parts of Wigston. I find one factory is worth a hundred of such consumers.

Mr. W. R. COOPER (Banbury): In our case we try to meet the small consumers as liberally as possible. We do nothing in the way of fitting up houses; and the consequence is that the tradesmen have gone more into the petroleum lamp than the gas-fitting business, as, after selling the lamps, they continue to supply the oil. I thought of suggesting to the Directors of my Company that they should try and revive the trade in gas-fittings by offering the tradesmen a premium upon all the gas-fittings they sell; so that there might be a fair competition with the lamps.

Mr. NORTH: Why not go into competition with them? You can afford to sell gas-fittings cheaper than they can.

Mr. W. WINSTANLEY (Newcastle): I should like to ask if any members present have tried the prepayment meter. I was instructed by my Committee to obtain one of these meters to experiment with. I have done so; and I find that the pence dial works backwards. It may be that this is right, to show the amount of gas paid for and the quantity to be burnt. I have tried it with a penny; but the penny will not go down. There it sticks; and still the gas goes on burning. (Laughter.) One of the members has spoken of supplying the services free. I do not find that it has increased the ratio of consumption over what it was before adopting this principle. As regards the deposit system, perhaps that may interfere with the increase of consumption. In my case, 5 per cent. is allowed upon all deposits. I find that the bad debts have decreased, while the consumption has increased, which may perhaps arise from better collection. Mr. Simpson is very favourably circumstanced in the matter of cottage consumption; but if I supplied cottages in the way he does at Rugby, I should very likely find a few hundreds increase in bad debts. The idea of adopting the prepayment meter is to increase this class of consumption, and at the same time make sure of the cash.

Mr. SIMPSON: Is not the dial of the prepayment meter meant to go backwards when you put a penny in? It goes round to the 12; and you cannot put any more pence in. Perhaps you have broken the action with your penny.

Mr. HARRIS: There is a dial registering up to twelve or each penny put in. It goes forward—one, two, or three, and so on up to twelve; and then it travels back. I have the greatest confidence in the meter.

The PRESIDENT: As to the idea of increasing cottage consumption, although I agree with previous speakers that we should not take business at a loss, yet I think our aim should be to bring into our fold all consumers who will in the long run benefit us; and that we should not stick at trifles, but remove, as far as practicable, all the old discouraging restrictions to the use of gas from all consumers—small consumers though some of them may be. On the Continent, they look at the whole question very broadly. They bring the service from the street, and take it right up through the various floors of the house free of cost. No doubt charges for fixing meters, deposits, and for one thing and another are vexatious, and form a stop-block in the way of a small consumer entertaining the idea of using gas. I notice that during the discussion nothing has been said with respect to Mr. Lewis's figures, which he had so ably prepared for us in tabular form in the paper. One advantage of delaying the discussion upon it has been, as I said before, to give us time for a full consideration of them; and, availing myself of it, I thought I would ascertain for myself what was the cost of burning ordinary petroleum oil, as compared with coal gas. I am living in the country just beyond

the limits of gas supply, and am compelled to use oil-lamps. I use Hincks's duplex lamps with petroleum oil; and the oil costs 9d. per gallon delivered. With the flames of my lamp set at right angles to the photometer bar, I obtained an illuminating power of 21·52 candles; and with the edge of the flames towards the bar, only 12·01 candles, or 56 per cent. less (which is about 4 per cent. less favourable for the edge of the flame than Mr. Lewis found). One quart of the petroleum oil lasted 14 hours 12 minutes; the cost at 9d. per gallon being 2½d. or 0·16d. per hour. Taking the mean of the illuminating power of the flames edge and full, it is equivalent to 5·23 cubic feet of gas of 16-candle power per hour. Adopting 3·2 candles per cubic foot, at 3s. per 1000 cubic feet, the cost of an equal light by gas for the same length of time would be 2·67d. against 2½d. from the oil—or 3·42d. against the 2½d. if the comparison be made with the higher lamp-power of 21·52 candles. The power recorded for the full-flame tests gives a value of 1215 candle power per gallon per hour, as compared with Mr. Lewis's 1287 to 1459; and my tests bear out his calculations that oil at 9d. per gallon is about equal to gas at 2s. per 1000 cubic feet, of an illuminating value of 3·2 candles per cubic foot. I am, however, of opinion that, notwithstanding the improvements which have taken place in gas-burners, principally in those of high power, 3·2 candles per cubic foot is too high a standard to adopt for the comparison with petroleum lamps. Such lamps as these are principally used in places where ordinary fishtail or other flat-flame burners would be used if gas were employed; and with such I think that perhaps a mean between the late Mr. Hartley's figures, mentioned by Mr. Lewis, and 3·2 candles would be fairer, if not still too high a value for the comparison—3·2 being the result obtained at present with the standard Argand burner. Reckoning therefore, the value of the gas per cubic foot in candles, at an eighth less than Mr. Lewis has done, it alters the comparative cost of gas in his duplex burner table from 15·16d. to 17·31d. as against 9d., or nearly double the cost of oil; and at 2s. per 1000 cubic feet, 11·54d., as against 9d.—or 28 per cent. dearer. I quite agree with Mr. Lewis's statement in his paper that the truth should be known; and if we do not bring it out, or in any way attempt to "scotch it," it will nevertheless come to the front. I therefore hope he will excuse me in disagreeing with his figures as to the cost of oil compared with gas. From the experiments I have made, and my general knowledge as to the cost of petroleum, I feel that, as regards expense, light against light, we shall not be able to "defy all competition," without 17-candle gas can be sold as low as 2s. per 1000 cubic feet. Anything above that figure will, if cost alone be considered, put the general adoption of gas by very small consumers out of the question if looked at apart from the matters of safety and convenience, which are so much in favour of gas. Mr. Lewis has referred to a valuable paper by Mr. Dalglish. It would be valuable information if Mr. Dalglish would at some future time kindly add to his interesting figures the price of gas in the different towns to which he refers in his paper, where he shows that the non-consumers vary from 8 to 81 per cent. It will give us an opportunity of judging more fully if it is the price of gas which adds materially to the disposition of the non-consumer to use petroleum rather than gas.

Mr. J. T. LEWIS (Wellingborough): The discussion to-day has, I think, been on the whole favourable to the views I hold. Some members seem to consider it is not advisable to push the sale of gas in cottage property, without being quite certain that it is going to pay, or more than pay, for the extra expense incurred through dealing with this class of property. In my opinion, it is necessary that we should try and get hold of this class of consumer; and therefore we must, in the first instance, treat it as an experiment, and afterwards be guided by the results, which may entirely differ in different districts according to local circumstances. No doubt, in large towns, such as Birmingham, the migrating habits of many cottage occupiers makes it very difficult to supply them with gas on the usual terms; and the endeavour to do so, on the system of quarterly payments, might add to the bad debts account. If, however, a system of weekly collections was adopted, I believe this class of people might with advantage become our customers. The frequent visit would almost, if not entirely prevent loss; and although the cost of collection is greater, I think, this is preferable to a system of monthly collection, or the use of a prepayment meter, the employment of which would necessitate at least monthly visits, when perhaps at the end of the month you might find your customer had removed, or that the meter had been tampered with. I must congratulate Mr. Simpson upon the smallness of his bad debts, and also upon the average consumption of his cottages; both being very good. Mr. Millard is under a mistake when he speaks of Mr. Simpson and myself supplying meters free. We do not do that. In my own case, we charge 1s. per quarter for 3-light meters. In reply to Mr. Harris, as to the use of petroleum to heat shoemakers' irons, gas is largely used in our district for this purpose; and although it is possible to heat these irons with petroleum oil, and some do it, I have not met with anyone who could get a supply of gas on favourable terms who did not prefer gas for the purpose—the advantages being altogether in favour of gas. During the past few months, we have laid down mains for the supply of a village of 2000 inhabitants, where scarcely anything but petroleum oil was previously used for lighting purposes. Our price for gas there is 3s. 4d. per 1000 cubic feet, with 2d. discount; and at this price, I am glad to say that many of the people have taken gas, and were only too glad to get it, in place of petroleum—clearly showing that it is not altogether a question of

cost light for light. In this place I have been fortunate enough to induce some owners of cottages to put in gas pipes and fittings; so that the occupiers can take the gas on the weekly system, without any expense, beyond that of the gas consumed and the meter-rent. I should recommend Mr. Cooper to take the supply of fittings into his own hands, instead of offering a premium to the oil-lamp sellers on the gas-fittings they could sell. He could supply the fittings at less cost, and would understand the requirements of his customers much better than the shopkeepers, besides having the control of them in his own hands. With regard to the question which the President has raised, as to the amount of light given by an ordinary burner per cubic foot of gas, I adopted the value of 3.2 candles because I did not wish to be below the mark in my comparisons; but I quite agree with him that, in the bulk of cottages where oil is used, such a high value would not be obtained. I think his figures of 2.8 candles per cubic foot are quite high enough; and I should be perfectly willing to adopt his figure, if I was going over the matter again. In a paper read by Mr. L. T. Wright, late of Nottingham, before the Society of Chemical Industry,* he compared the value of petroleum and paraffin oils with gas as supplied at Nottingham. He allows a value of 3.5 candles per cubic foot for ordinary flat-flame burners. This I consider much too high, even when used with 18½-candle gas. With this exception, I find that his results agree closely with my own experiments; and I am pleased to know that our President's tests also agree with mine. It is of the greatest importance that we should make only true statements to our customers as to the value of the light obtained from the gas used with various burners. A short time ago a pamphlet was given me on the subject of the supply of gas to consumers; and in it I found very misleading statements, such as no one connected with gas undertakings should send out, and which would certainly lead to trouble with our consumers. Our President says that gas must not be above 2s. per 1000 cubic feet to be able to compete with petroleum. This is true when comparing the light given by each illuminant; but something must be allowed for the advantages which gas undoubtedly possesses over petroleum. As an instance of this, I may mention that a few weeks ago I attended a meeting of manufacturers and others held in a village of 3000 inhabitants, to take into consideration the advisability of obtaining a supply of gas; and without any figures being given them, their own conclusion was that, if gas could be supplied at 4s. per 1000 cubic feet, they would burn it in their homes and factories instead of petroleum. Notwithstanding that petroleum is such a severe competitor, I think if we take such steps as weekly collections, and offer every facility for getting gas, we shall do a great deal to meet, if not to stop altogether, the competition which we are experiencing at the present time. Though I cannot speak definitely on the subject, it may interest some to know how we have succeeded with the weekly system since we started it in July last. During the quarter we had 16 consumers on this system—the lowest average weekly payment, 3.3d., and the highest where a cooking-stove is used, 1s. 7.6d., or an average for each of 5.94d. per week. We have now 30 customers on this system, and have orders for many more to be put on. In conclusion, I beg to thank you for having listened to me so patiently.

Mr. COOPER: With regard to the question of offering premiums to tradesmen, my idea is that in doing so we should not create a rivalry; we should not have any bad debts, and there would be no capital required for carrying out my suggestion.

The PRESIDENT: I rise to move a very hearty vote of thanks to Mr. Lewis for his paper, which has been so well discussed to-day. I hope some other members present will take a leaf out of his book, and bring before us next year papers on subjects of mutual interest.

Mr. B. W. SMITH (Smethwick) seconded the motion, which was carried with applause.

Mr. LEWIS: I thank you very much. I only felt I was doing my duty in preparing the paper. I shall be pleased at any future time to do anything I can for the Association.

METROPOLIS WATER SUPPLY.—Among the notices of motion still on the paper of the House of Commons, there is the one by Mr. Dixon-Hartland for the appointment of a Select Committee to "inquire into the whole question of the present and future water supply of the Metropolis," and that of Mr. Seager Hunt for a Bill "to consolidate the Acts relating to the water supply of London," both of which were recorded in our columns at the time the notices were given.

AWARDS AT THE BRUSSELS EXHIBITION.—In addition to the awards at the Brussels Exhibition which have already been recorded in our columns (see *ante*, p. 674), we notice that diplomas of honour were given to M. Somzée, for the "Ezmos" gas-lamp (described elsewhere to-day); to Messrs. Marsh, Greenall, and Co., of Manchester, for their gas-lamps; and to the same firm, as well as to Messrs. C. Wilson and Co., of Leeds, and M. Wybauw, of Brussels, for their gas-stoves. Mr. Jennings and Mr. Justice, of London, have received silver medals for their gas-stoves; and Herr Elster, of Berlin, a gold one for his photometers. Messrs. J. Stott and Co., of London, were awarded a special prize for their gas-regulators. For gas-meters, the General Gas-Meter Company of Brussels, MM. Bieunen and Serret, of that city, and Herr Haas, of Mayence, were all awarded gold medals.

THE GUIDE-FRAMING OF GASHOLDERS: HOW, AND HOW FAR, MAY IT BE DISPENSED WITH?

By GEORGE LIVESEY.

[A Paper read before the Southern District Association of Gas Engineers and Managers, Thursday, Nov. 8, 1888.]

The question has two aspects—the first is a scientific, and the second an economical problem. Supposing the first to be settled satisfactorily in the affirmative—that guide-framing can be abolished partially or entirely—the theory is not likely to be adopted in practice unless a considerable saving can be effected.

It has been proved, both theoretically and practically, that the guide-framing of telescopic holders can be safely reduced in height without appreciably increasing the strength of the holder or the remaining guide-framing. The theory is to be found in the series of able and exhaustive articles, by "Theory and Practice," that have appeared in the JOURNAL OF GAS LIGHTING (which I hope will be published separately); and the practice is to be seen at Rotherhithe. So far as the Rotherhithe holder is concerned, the idea originated in 1881, as may be seen by referring to the JOURNAL for Dec. 27, 1881, where, in a letter referring to the large holder then just completed at the Old Kent Road, I said:

"I close this letter with an idea that has occurred to me this week, and which may some day be carried out in practice. I believe it would be quite practicable and perfectly safe to erect and work such a gasholder as this with three lifts of 53 feet each, if the guide-framing reached only high enough for one lift—say 55 feet [of this I am now doubtful] in order to guide the inner holder until the second is cupped. The process would then be repeated; the second lift being guided and kept in its place until it lifted the third, which would rise to its full height and be held firmly in position by the combined radial and tangential rollers on the grip of the outside or bottom lift with similar rollers on its curb working against guides in the tank."

The principle was tested soon after by telescoping a small holder about 8 feet diameter by 8 feet high—the inner lift having no guide-framing; and the experiment being successful, the large holder at East Greenwich, just completed, would have been built with a shortened framing, had we not been advised that the stresses on the unsupported part of the holder would be of such an entirely novel and serious nature that it would not be safe to try an experiment of this kind on so large and exposed a structure. The first attempt in this direction was, therefore, made in 1887 (but designed in 1886) on a more modest scale at Rotherhithe, where an ordinary double-lift gasholder, erected in 1867, 150 feet diameter by 25 feet deep, with sixteen cast-iron columns 50 feet high, and two tiers of girders, has been converted into a three-lift holder without increasing the height of the original framing, or strengthening it beyond what would have been necessary had it been carried up the extra height. The strengthening consists simply of diagonal bracing; and the only additional expense was replacing the channel-iron guides with H-iron to furnish paths for the combined radial and tangential rollers on the grips of the middle and outer lifts. These tangential rollers are the only addition to the holder necessitated by the shortened framing. The experiment, therefore, proves that a double-lift holder can thus be safely converted into three lifts with advantage on the score of economy, which is its justification; but it is very doubtful whether the ordinary framing can be further reduced without adding so much to the strength of both framing and holder as to prevent any further saving.

In the first place, according to the accompanying diagram (copied from an article by "Theory and Practice" in the JOURNAL of Sept. 25 last, p. 547), in a three-lift holder with framing two lifts high, the stresses on the framing are not appreciably increased; but with framing only one lift high, they become very seriously augmented—necessitating great additional strength. Secondly, there are the stresses on the bell, which are dealt with in the article on page 963 of the JOURNAL of Nov. 29, 1887, where it is said that "gasholders can be constructed safely with the inner lift unsupported by external guide-framing after it has cupped, providing the guide-framing is carried to the height of the two outer lifts." But the writer, dealing with "three-lift holders one lift supported by guide-framing," says (speaking of the side sheeting acting as the web plate of a girder) the diagonal strains tending to distort and buckle the sheeting would be so great that he comes to the conclusion "that it is not safe nor advisable to make treble-lift gasholders with guide-framing to the outer lift only." These conclusions are repeated in his article on page 677 of the JOURNAL for Oct. 16 last; and until these conclusions are proved to be erroneous, he would be a bold, if not a rash, man who ventures lightly to construct a three-lift holder with ordinary guide-framing to the height of one lift only.

But "Theory and Practice," at the close of the last article above mentioned, has a "Note on Mr. Gadd's Gasholder," which shows that, by a different form of guiding, the method of determining the strains must be different; and this points to the possibility of further reducing or abolishing the framing, and brings us back to the

article in the JOURNAL for March 29, 1887, and to Mr. Webber's paper of last year—to whom undoubtedly belongs the credit of the really original idea of constructing and working gasholders without external framing. Until he suggested the idea, it had never, so far as I know, been even thought of; and if gasholders should ever be so constructed, the merit of the suggestion rests with Mr. Webber. After this, it occurred to me that if some means could be devised whereby the bottom curb, while free to rise and fall, could be maintained perfectly level, a great step would be made in the direction indicated by Mr. Webber. I said in the JOURNAL for April 26, 1887, "if some practicable means could be devised whereby all the bottom rollers might be made to rise or fall equally, and none of them could either rise above or fall below the others, the holder would then to all intents and purposes have a solid foundation, and no columns or guide-framing of any kind would be necessary." Thus a holder rigidly level would be secured; and at the same time it would be free to move up or down with the inflow or exit of gas. For some time, however, the accomplishment of this object appeared impracticable; but Mr. Gadd's ingenious and novel invention of spiral guides seems to have solved the problem.

The important question now is whether, by Mr. Gadd's or any other plan, it is advisable or practicable to dispense entirely with guide-framing for telescopic holders, having regard to the want of strength in the side sheets to resist the distorting and buckling strains in an unsupported holder. By Mr. Gadd's invention we are enabled for the first time to hold the bottom of a holder in a horizontal position. It is not like a cylinder simply standing on a solid foundation; but is a cylinder (closed at the top) supported from the crown with the sides suspended therefrom, and the whole held firmly level by the rollers acting on the spiral guides. But I cannot see that this diminishes the distorting and buckling strains on the side sheeting of an unsupported holder. If, however, these strains can be proved to be of no great moment, then Mr. Gadd will have shown how Mr. Webber's idea of no framing can be made practicable.

Assuming that for single holders, or shallow telescopic ones, unsupported by guide-framing, the idea of holding the bottom curb to be successful, we have in the next place to find the simplest plan of effecting that object. We have Mr. Gadd's clever application of the screw or inclined guides; and I have now to introduce an upright guide to effect the same purpose. It is either made in channel form with a single tangential roller, or solid with a tangential roller working on each side. In the case of the channel guide, the roller must be carried on a stud unsupported at the outer end; but with the solid guide, the rollers work on pins supported at both ends—thus having the advantage of greater strength. The peculiarity of the guide consists, as shown, in alternate projections and hollows on the sides. The projections on one side are opposite to the hollows on the other, against which the roller or rollers work; thus compelling them to take a zig-zag course. This produces in the holder in its rising or falling a slight alternating movement on its vertical axis—turning, in fact, like a top on its centre, but only to a very small extent in one direction (say) to the right, when the action is reversed, and it moves to the same extent to the left; then again to the right; and so on. The projections may vary in size and shape; but here they are shown as equal to one-fourth the diameter of the rollers—say, 3-inch projections for 12-inch rollers—and as the zig-zag path is of exactly the same width as the rollers, there is thus 6 inches clear between the projections on the side of the guides, which may be used as a path for radial rollers if required.

The guides being fixed either to the side of the gasholder or to the tank, in exact correspondence, the closely fitting rollers must of necessity all move together in the same direction, and to the same extent. Consequently tilting is prevented; the bottom curb being held rigidly level, though perfectly free to rise and fall. The overturning force of the wind is resisted in an entirely different manner to that of ordinary framing. The rollers on the lee side hold the curb up, while those on the windward side hold it down; whereas with ordinary framing tilting is resisted by two or more series or circles of rollers at different levels bearing on the guide-framing. In one case the base is secured; in the other, the sides are supported. The difference, therefore, is radical; and it may bring Mr. Webber's idea within the range of practical engineering. Of course, the effect arrived at with the corrugated guide is the same as Mr. Gadd's spiral; and it is not my intention to disparage the latter, or to draw comparisons between them. If both accomplish the same object, it remains for impartial practical men to determine which is the more suitable for the purpose; and if any should prefer mine, they will not find that the protection it was necessary to obtain in the form of a patent will prove an obstacle to its adoption.

If either the spiral or corrugated, or both forms of guides prove effective, it will then no doubt be practicable to work single gasholders, or small and shallow telescopic ones of two or possibly three lifts, without guide-framing, as holders of this kind are proportionately much stronger than larger vessels—the sheeting being of about the same thickness in both cases. If successful, it will remove the objection to shallow holders; and in fact will make them both economical in construction and safe in working. Expense will be saved in the tank; while the holder of four, five, or possibly more lifts, with the cups at comparatively short distances apart, will be better able to resist the diagonal strains that tend to distort and buckle the sheeting if unsupported by guide-framing. For large and deep holders the utmost I expect from the new form of guiding is that, by reducing the strains on the guide-framing, it will not be necessary to increase its strength when leaving two lifts out of three or more unsupported. Beyond this, as the new guiding arrangements do not in any way affect or diminish the strains on the side sheeting of the part of the holder which is not supported by framing, the danger of distortion and buckling renders it impracticable to work the three lifts of a large and deep holder guided from the bottom curb only, without greatly increasing the strength of the side sheeting, and so adding to its weight and cost that all advantages would disappear and the balance be left on the wrong side. Let us hope that on this point there may possibly be a mistake; and that all the predictions and hopes of the enthusiasts will be satisfactorily developed in practice.

SOME HINDRANCES TO THE SALE OF GAS.

By W. E. PRICE, of Hampton.

[A Paper read before the Southern District Association of Gas Engineers and Managers, Thursday, Nov. 8, 1888.]

Given an efficient plant, and the wherewithal to work it, a gas engineer, with a sound knowledge of gas making in all its branches, is quite prepared to produce as much or more gas than may be required; but his energy is far from being less needed when he has delivered it into the gasholder. He has then to put forth his best efforts to find what most commercial men have more or less difficulty in finding—a ready and increasing market for the article which he has manufactured.

Like with most commodities or necessities, the demand for gas is regulated by its comparative cost to the public, taking into consideration its advantages and disadvantages compared with that of other illuminants; and we, as commercial men with an article to sell, ought to leave no obstacle in the way of preparing a smooth path for the use of gas. We must not forget that there are other means of obtaining artificial light—from the tallow dip to the electric arc; and if we wish to see the demand for gas increase, we must remove all real obstacles to its use. Wherever we see a supposed advantage in a rival illuminant, we must endeavour to remove our corresponding disadvantage; so that the public may not give two thoughts to another light in their necessary and wise considerations.

Let us suppose for a moment that we know nothing of the manufacture of gas, but are desirous of becoming consumers of that article. The first obstacle that "ruffles our feathers" on applying at the gas office is the demand for a deposit. On principle, we object to the prepayment of a certain sum of money as a bond of our honesty; or, even if we manage to put up with that, we think that it is only reasonable that interest should be paid on the money deposited, which, I believe, the majority of companies refuse. No! Deposits, especially when demanded in an arbitrary manner, and with much red-tapeism, cause more dissatisfaction against gas companies than any other item in their dealings. Cannot we dispense with deposits in the majority of cases? The method I have adopted for some time past is to inquire of the applicant the company who last supplied him with gas, and then to make inquiries of that company as to whether the said person may be depended upon for the due payment for the gas consumed by him—not forgetting to enclose a stamped envelope for a reply. I do not think there is a manager to be found who would object to give such information under the circumstances. If the answer to the inquiry is not satisfactory, then is the time to require a deposit or some other form of security.

The next more or less heavy expense which a consumer has to

* The dotted lines show the paths of the centres of the rollers.

bear is the whole or part cost of laying the supply-pipe from the company's main to the meter. This, in my opinion, ought to be borne by the landlord, as it is obviously to the benefit of his property and future tenants when the gas is laid on. The cost of fixing the meter is rather a different matter, and is a fair charge to make on the consumer; seeing that it is for his use only. But in this case, as also in that of services, the cost price only should be charged. A gas company should not seek to reap much or any profit from the actual connection of a house with the mains, as all charges of this class are obstructions and detrimental to the use of gas. Let a fair interest on all initial outlay be taken into consideration, when the selling price of gas is decided upon. This will probably only amount to a penny or so per 1000 cubic feet, which does not appear much in this form, especially when new consumers are reminded of the great advantage of being relieved of all primary outlay. In isolated cases, where it would be unwise to maintain the present charge per 1000 cubic feet on this account, the method now being tried by one of the London Companies in reference to internal fittings—viz., a weekly, monthly, or quarterly rental which is a fair interest on the outlay of providing a house with gas-fittings—might be extended to the external pipes.

The next item we have to consider is meter-rents. This is another source of dissatisfaction with consumers. Many have been the emphatic opinions expressed to all of us of the unfairness of this charge, especially in the case of old consumers, who have perhaps paid rent for their meters for 15 or 20 years. The reminder that even a gas-meter will not last for ever is not always convincing. The average consumer does not see, and cannot be made to understand, why he should pay rent for an instrument which he has not the least interest in having fixed at his house. All present know the prejudice of the public against gas-meters. The majority look upon them with great disfavour as one of the necessary evils of civilization—in use, only to be distrusted; out of use, nearly as bad. Unreasonable as we know this opinion to be, still we have to deal with it as it is; and our endeavour ought to be to disperse the idea in every possible manner. Experience has proved that the abolition of meter-rent will do this to a great extent. As with the application of gas to a house, a fair interest on outlay for meters could be charged on the selling price of gas.

Having laid on the gas for a new consumer without saddling him with any serious initial outlay, we find that our troubles are not over. Before long, we shall perhaps receive from him a complaint that the light is very insufficient and far from good. We call upon our friend; and, as we anticipated, we at once discern the cause of the complaint—bad fittings and worse burners. And what an extraordinary amount of reasoning will an average consumer listen to before he will believe that your accusation against his fittings is the cause of the complaint. He will not be convinced until you have found a bracket that will pass sufficient gas, and have fixed to it a burner which is suitable for the quality of gas supplied and the quantity required. Then only will he believe that the fault lies in his fittings and not in the gas. We have all been astounded at the miserable class of burner often used—some actually being new, or nearly new—which are entirely unsuited to the quality of gas supplied. These are generally fixed with the idea that their use will have the effect of reducing the gas bills; whereas we all know that the reverse is the case. To make matters worse, unscientific inventors are continually placing on the market burners of supposed remarkable economy, which, in reality, are nothing more nor less than mechanical means applied to unsuitable burners, with increase of cost and disfigurement of the flame, to secure a result obtained and generally surpassed by the use of an ordinary burner of suitable size. I am a strong advocate of governor burners. They are cheap, and burn the gas under the most favourable conditions, always giving a steady and uniform light, under the usual variations of pressure. I think the action of the gas company I have referred to is a step in the right direction—supplying and fixing suitable fittings and burners in the consumer's house at a weekly or quarterly rental; and I hope that it will be attended with success, and that their example will be followed by other companies who wish to maintain good relationships with their consumers. We shall then be able to see that consumers are supplied with pipes, fittings, and burners suitable for their requirements, and thereby give satisfaction.

We have often to listen to, and successfully combat many more or less serious objections to the employment of gas. Many people complain of the injury to plants and health; and that the atmosphere of rooms in which it is used soon becomes unbearably oppressive compared with rooms where other means of illumination are used. This is no doubt a fact in very many cases; but is it not rather a point in favour of gas than otherwise, inasmuch as it soon discovers those rooms which, through bad or complete absence of ventilation, are not fit for human habitation? Those who make this complaint, and declare that previous to the use of gas no such oppressive feeling was experienced, forget that they are now using perhaps three or four times the amount of light they were contented with when employing oil-lamps or candles, and that they are now not only illuminating the table they are sitting at, or the book they are reading, but are enjoying the pleasures of a room well-lighted from floor to ceiling. The adoption of gas has unpleasantly reminded those people that the rooms which they have been using are nothing but inverted receivers of carbonic acid and other deleterious gases given off by the occupants of and illuminating agents in the rooms, with perhaps a few outlets in the form of cracks in the doors and windows. These promiscuous outlets were sufficient to prevent any oppressive

feeling whilst an isolated light was being used; but when universal illumination is adopted, the unscientific nature of the ventilation becomes painfully apparent. To complain of the gas is as bad as a patient quarrelling with the doctor who informs him that he is suffering from a serious disease.

We cannot speak too highly of the introduction of the inverted regenerative burner; for in it we have the best and simplest means of converting the oppressiveness of an ill-ventilated room into the coolness of a conservatory if need be. I have had experience of such a room in my own house. My dining-room was built without any attempt at ventilation; and so a few years ago I inserted into the centre of the chimney-breast one of Boyle's mica flap ventilators, which was connected with the chimney. The result is that, whereas previously I noticed a difference of from 15° to 20° in the temperature between the level of the ceiling and 4 feet from the floor, it is now reduced to 10° or 12°. At this time we had two of Sugg's Christiana burners in use on brackets over the mantelpiece. Last year, however, I fixed a ventilating regenerative burner in the centre of the ceiling, communicating, through a perforated ceiling rose, with a box and 4-inch square iron tube, which was carried into the chimney. The result is that the thermometers, fixed in the same relative positions, only indicate now a difference of 2° or 3°. So much for the exit of the heated gases; but provision quite as important must be made for ingress of fresh air. This I provided by means of a 6-inch channel laid under the floor in connection with the outer air. There is an opening close to the skirting in the room regulated by an adjustable plate, and another inside the fender 6 inches square, which is covered by a perforated plate and a sliding regulator underneath. This plate takes the place of one of the hearth tiles. In this way I obtain a regular supply of air for the room, and what is quite as important to prevent draught, a good supply of air direct to the fire which has not to travel across the room, after having obtained ingress from under doors and windows, chilling the feet and ankles of the occupants. It is therefore our duty to demonstrate to the public that gas, instead of being an opponent and a hindrance to ventilation, is really its best friend and helper.

Seeing that we have so many prejudices to overcome, and many objections, though of a frivolous nature, to dissipate, is it not important that their number should not be increased by a high charge for gas? Have not nearly all of us found that the reduction in the charge per 1000 cubic feet, though perhaps made with a certain amount of fear and trembling for the next dividend, has, in most cases within six or twelve months, resulted in an increased consumption, which has been sufficient to compensate for the expected reduction in the revenue. We do not need any authority to tell us that it is a mistaken policy to maintain a comparatively high price for an article; for we all know that in 99 cases out of 100 a timely reduction means an increase in the revenue. I believe a plan of discounts given to consumers in proportion to the amount of their consumption is much appreciated, and also a general discount for prompt payments—say, within a month. I have no doubt that most of you can call to mind instances where both of these policies have shown very good results.

In spite of the great reduction in the price of gas, and the consequent increase in consumption in the last ten or fifteen years, there still remains a fairly distinct line below which the use of gas has not to any appreciable extent been adopted; and this line may be drawn at the artisan class. We have not far to search for the cause of this. We have no reason to suppose that it is through any hereditary love for the tallow dip or the paraffin-lamp. Is it not plainly evident that the cause lies in the fact that our average working man cannot purchase his gas as conveniently as he can his present means of illumination? If the British workman could purchase his weekly supply of gas as easily as his equal supply of paraffin, I doubt not that this pungent liquid would be a drug in the market. Provided that he can obtain his gas without any serious initial outlay, and procure a continuous supply in quantities within his means, there is little doubt that the artisan would universally adopt it. Methods have been suggested, and in some cases adopted, in order to secure this means of increasing revenue; but I fear that any such proposals as weekly or monthly payments, though realizing their object, would add considerably to the cost of collection.

Recognizing these difficulties, I have designed a prepayment meter, which, Sir, I hope I may be allowed to describe. This instrument, whilst allowing an easy payment, obviates the necessity of collections more often than circumstances conveniently permit. The meter (a sample of which is before you) is constructed to receive a coin, and to deliver, as many be required, its equivalent value in gas. It is of simple construction; the principle being to deal with the gas before it enters the bellows or drum of the meter, and to allow a certain amount of gas to pass, equal in value to the coin inserted; and then, by means of a valve, cutting off any further supply until another similar coin be introduced. The supply is not suddenly stopped; but warning is given for about an hour before the supply ceases, by the lowering of the lights, which instantly resume their usual proportion upon the insertion of another coin. The coin is inserted in the drawer in front, which is then pushed home, opening the valve, and admitting the gas. The small dial indicates the passage of gas to the value of one coin; so that by its inspection the consumer may know exactly the proportion of the coin expended and that to come. These meters can be made to receive a coin of any value; but I find that those to receive sixpence or a shilling are the most suitable for small consumers, whilst one for half-a-crown would be better for large

consumers. No alteration is made in the shape of the meter; and there is but little addition to its height.

There appears to me to be great advantages in the use of a meter of this description; for thereby more than one obstacle to the use of gas is removed, with consequent benefit to gas companies. In the first place, it brings gas within the reach of any person who can afford to rent a room, and to use an artificial light. And what an enormous increase to a gas company this means, perhaps though too sudden to be appreciated by all. In the second place it secures the company from bad debts; being on the cash-before-delivery principle—thereby returning a greater revenue from the sale of a given amount of gas; and consequently obviating the necessity for the demand of a deposit, which alone means the removal of a great source of annoyance and anxiety to gas companies. Besides these uses, it is well adapted to that of consumers who wish to keep a check upon extravagant consumption by servants and others—in fact, more than one consumer has expressed his wish to have one fixed. Said one: "I cannot understand your present meters with their mysterious pointers and their hundreds and thousands; but I do know what has happened when a shilling is taken out of my pocket. Now I have to wait till the end of the quarter before I know of any extravagance; but with this meter I can keep a check twenty times in the pound."

THE "DELMAS" AND "EZMOS" REGENERATIVE LAMPS.

At the congress of the Société Technique du Gaz en France, held in Boulogne last June, M. Giroud described a new horizontal-flame recuperative burner devised by M. Delmas-Azéma. The appliance, which is shown in the accompanying engraving, fig. 1, is a modification of his vertical-flame burner, of which an illustrated description appeared in the JOURNAL for Feb. 23, 1886 (p. 349); and it possesses certain features of interest. The burner consists of a heat regenerator composed of cast iron, having in the centre a chamber A for carrying off the products of combustion, surmounted by a chimney of variable length in proportion to the quantity of gas consumed. Around this chamber, where the combustion products give up the greater portion of their heat, there is

FIG. 1.

another, which is attached to the central chamber by partitions, which serve to conduct the heat, and direct the descending current of the air, which is heated by coming in contact with the sides of the chambers. The outer chamber is closed over a third of its surface and underneath, as far as the portion which faces the burner is concerned, as well as at a height of 0.5 to 0.6 inch above the enamelled reflector B, which closes the under side of the recuperator. The passage thus formed allows the products of combustion to pass into the chamber A, and thence into the chimney. The partitions on the other two-thirds of this chamber descend to the reflector, but terminate above at a certain distance from the outer casing of the lamp, so as to allow the air entering by the orifices O (which are pierced all round the lamp) to descend the annular space, and feed the flame on all sides at once. Above the burner, and extending over a quarter of the circumference on each side, there is a curved plate, by which the stream of fresh air is directed horizontally above the flame. Another stream of air is supplied to the under side of the flame, which is thus caught between two currents of hot air, which support combustion, and very considerably increase the illuminating power of the gas. The flame is slightly hollow in the centre; but the edges never impinge against the reflector, from which they are kept by the upper stratum of air. The burner, it is stated, gives almost as much light as is afforded by the one in which the flame is vertical, although the illuminating surface is very much less. The lamp may be lighted from the side by a flash-jet, as shown; or a taper may be passed down the chimney. The appliance has been in use for several months at the oil-gas works of the East of France Railway, and, up to the present, the results are stated to have been satisfactory. With a consumption of about 0.7 of a cubic foot of gas, the light of one Carcel (9.5 candles) has been obtained; while a like quantity of

FIG. 2.

gas consumed by the same burner in free air only yielded about 6 candles. So that an increase of 50 per cent. in illuminating power is secured without additional expense. As soon as the appliance is heated, the flame becomes very steady; and the lamp may even be inclined at a considerable angle without detriment to the shape of the flame.

The lamp shown (partly in section) in fig. 2—the "Ezmos"—is not a new one; having been designed about six years ago. Though unknown in this country, it has met with a certain amount of success in Belgium; and has lately gained distinction by carrying off the highest award at the Brussels International Exhibition. Our purpose here being merely to acquaint our readers with the construction of the lamp, we shall not discuss its merits as compared with the other regenerative burners with which it competed. At the same time it may be pointed out that the extraordinary name given to the lamp is simply that of the projector and chief of the Executive Committee of the exhibition—M. Somzée—concealed under the very thin disguise of the simplest form of anagram; and in view of this fact, it is not unnatural to suppose that its performances were regarded with a certain amount of prepossession in its favour. However this may have been, the lamp took the prize. The appliance differs from its fellows mainly in the arrangements for effecting the combustion of the gas. Efficient combustion may be said to be between the two extremes of a red and smoky flame, and that condition of complete combustion which is accompanied by considerable heat. While most of the regenerative burners fail to hit the "happy medium" in this respect, the designer of the appliance under notice flatters himself that he has succeeded. He claims that, unlike other lamps of this type, the "Ezmos" is able to accommodate itself to surrounding conditions; and therefore its action is undisturbed by exterior influences. The supply of air enters the lamp in one direction only, and this has the effect of giving steadiness to the flame—an important feature in a high-power burner. An additional advantage claimed for the lamp is that it is of simple construction, and that its form favours the employment of enamelled iron, which, by resisting the action of high temperatures, prevents loss of heat, and thus facilitates regular combustion. The lamp is composed essentially of a recuperator R, against which the products of combustion strike passing into the chimney C, and which terminates in a cylindrical tube D. Upon the recuperator is fixed a plate of enamelled iron H, forming a reflector, and having around its outer edge a number of small holes O, whereby the supply of air is admitted into the lamp. The casing E, which forms a portion of the chimney, stands directly upon the plate H, being sustained by the support N, the purpose of which is to deflect the current of hot air passing into the chimney. The gas arrives by the pipe T, which is in two sections, united by the junction-piece M. The upper part of this pipe is open, as shown; and the lower ends in the burner B. The curved piece of metal projecting from the cylinder D serves to give the flame the shape shown at F in the illustration; and, by radiating a certain amount of heat, stimulates into action the entire surface of the flame. The globe G, fixed upon the outer rim of the lamp K, is sufficiently large to afford ample space beneath the flame to ensure perfect combustion.

THE LAYING OF LARGE MAINS.—This was the title of a paper read at the meeting of the Liverpool Engineering Society last week by Mr. R. S. Wyld, M. Inst. C.E. The author, after referring to the ancient aqueducts, stated that the power to construct iron to the different materials of which a main might be constructed; pipes had only been obtained within the past century. He alluded and adduced arguments in favour of cast iron—stating that the larger the main the more water was delivered relatively to the weight of the iron employed. He referred to various means of transit over rough ground, and appliances for laying large pipes in the trenches. The necessity for sluice drains in every hollow, and an air-cock at every summit, was dilated on; preference being expressed for a simple hand air-cock, with an additional aperture always open, permitting a slight leak, but preventing any accumulation of air. Drawings of some of the works on the Vyrnwy aqueduct were shown (by permission of the Engineer, Mr. G. F. Deacon, M. Inst. C.E.), to illustrate the manner in which such obstructions as rivers, railways, and canals were overcome.

THE KING OF THE BELGIANS' "PURE DRINKING WATER" PRIZE.—Further particulars are to hand of the conditions under which the next award will be made of the prize of 25,000 frs., which it will be remembered that the King of the Belgians founded in 1874 for eminent services rendered to science. The prize for 1893 is to be for the best solution of the question how large cities are to be most efficiently provided with abundant supplies of pure drinking water. In solving this question, the local conditions of Brussels are to be dealt with in the first place; but probable increases in urban populations generally are also to be taken into consideration. Works already in print will be admitted to the competition only if the new editions contain important changes and additions which, like the other prize essays, have been published during 1889 to 1892—the period fixed for the competition. The prize essays may be in Dutch, German, English, French, Italian, or Spanish, and must be sent in by Jan. 1, 1893, to the Belgian Ministry of Agriculture, Industry, and Public Works. The jury (to be appointed by the King of the Belgians) is to consist of three Belgians and four representatives of other nations.

Register of Patents.

ENRICHING AND BURNING ILLUMINATING GAS.—Porter, G., of Callum Street, London. No. 15,670; Nov. 15, 1887. [11d.]

This invention relates to gas-fittings furnished with means for enriching the gas in its passage to the burner; and it has for its main object to so construct and arrange the enriching or carburetting apparatus that it can be easily taken to pieces for the removal of the interior—for the purpose of cleaning or removing the accumulation or deposit which always takes place in carburetting apparatus. The tube conveying the gas from the supply-pipe to the vessel or receiver containing the carburetting material, and also the tube which passes the enriched or carburetted gas from the receiver to the burner, is arranged within a tube; all or some of the tubes being fitted in bodies screwed into the centre of the carburetting vessel, so that by unscrewing the bodies the tubes are removed for cleaning or for other purposes. The conductor is formed with perforations; a second or twin conductor being placed over the perforated conductor, whereby a great amount of heat from the burner is directed to the material in the carburetting vessel. In the case of pendent lights, it is sometimes advantageous to employ only the tube or tubes for conveying the gas into the carburetting vessel; the carburetted gas passing to the burners through the space between the supply-tubes and the outer tube forming the fitting. In this arrangement legs or rods are employed, which extend from the fitting into the carburetting vessel, to serve as conductors for the more equal distribution of the heat through the carburetting material. In the case of regenerative gas-lamps, the receiver or carburetting vessel is arranged around or above the chimney, which forms the conductor for heating the carburetting material. A pipe conveys the gas from the supply-cock into the carburetting vessel; the enriched gas passing from the vessel through a pipe opening into the central gas-supply pipe.

[A large number of illustrations of various forms of lamps constructed according to this patent accompany the specification.]

INJECTING LIQUIDS INTO GAS-RETORTS.—Good, R., of Carshalton. No. 16,866; Dec. 7, 1887. [8d.]

By this invention, to introduce liquids, such as crude petroleum or shale oil, into a hot gas-retort, the patentee employs a syringe or single-acting force-pump. The nozzle of the syringe or pump is provided with an india-rubber surface, which, when pressed against a cock in the retort-lid, forms a tight joint. The mouth of the cock is made to a knife edge, so as to form a tight joint on the surface; and the piston of the pump is provided with an india-rubber surface, which at the end of the stroke comes against a ring inside the barrel surrounding the opening to the nozzle. The pump is filled with the liquid it is desired to inject into the retort; and its nozzle is pressed against the cock in the retort-lid. The cock is then opened, and the liquid forced in. At the end of the stroke of the pump, the surface on the piston comes against the ring surrounding the nozzle, and makes a tight joint, so as to prevent any back flow until the cock is shut and the pump can be removed.

AUTOMATICALLY GENERATING GAS FROM LIQUID FUEL.—Brotherhood, C., of Redland, Bristol. No. 1315; Jan. 28, 1888. [8d.]

This invention consists in apparatus constructed and arranged for the production, in an automatic manner, of gas from oil and other liquid fuel.

The oil for conversion into gas is supplied from a reservoir A situated at such a height as to afford a suitable head for the flow therefrom of oil to the retort, and also to afford the required pressure of gas, by means of an adjustable stuffing-box and set screw below it. Or the cistern may be fixed, and a ball-cock employed governing the flow of oil through the pipe D. By the syphon E the reservoir communicates with the retort F contained within the heating chamber G. The pipe is fitted with a cock and with a "sight-feed" appliance I for observing the flow of oil to the retort. The heating of the retort is effected either by combustion of solid fuel placed on the fire-bars K or by gaseous fuel in combustion supplied to a perforated burner T; but when solid fuel is employed, the burner is withdrawn. The products of combustion escape preferably by two chimneys L, situated at the opposite side of G. The gas generated in the retort passes out through the outlet-pipe M, by which it is conducted (either directly or through a receiver or collector) to the point of consumption. The pipe M is fitted with a safety-valve O, consisting merely of a syphon tube containing mercury. If, while the stopcock of the outlet-pipe is closed, oil be admitted to the retort and subjected therein to the action of the fire, the pressure of the gas generated will, in due time, reach a point at which the column of oil is balanced, and the flow of oil to the retort thereby suspended; but on opening the cock, the gas escapes, and the equilibrium, of course,

is destroyed. The oil then resumes its flow to the retort, and the production of gas is continued. Towards the lower end of the spindle P is a valve having an orifice extending through it. The spindle is connected at the upper end to the lever Q, towards one end thereof. At that end of the lever is a balance-weight; while at the other end it is connected to the spindle R extended into a chamber, and attached at the lower end to a flexible gas-tight web or diaphragm secured to the underside of the chamber. The chamber communicates with the receiver S, to which gas is supplied by the pipe M. As the pressure in the chamber R varies with the demand made upon the gas, the web or diaphragm is acted upon accordingly; and the valve is opened or closed through the medium of the counterweighted lever Q—the arrangement being such that a reduction in pressure in the diaphragm chamber causes a corresponding opening of the valve in P, and affords an increased supply of gas to the burner.

BUNSEN GAS-BURNERS.—Imray, O.; communicated from C. Auer von Welsbach, of Vienna. No. 5722; April 17, 1888. [6d.]

This invention relates to the construction of a Bunsen burner in such a manner as to produce a circular flame with internal as well as external air supply.

The gas, entering at the bottom, passes vertically through several small holes in a thin plate G into a cavity A, into which air enters through lateral apertures X. From the cavity the gas and air ascend a tube T, which expands at its upper end to a diameter equal to that of the desired flame. The expansion is covered by wire gauze W, which serves to mix the gas and air, and distribute the mixture uniformly through the enlarged part B of the tube. The mixture then ascends an annular passage C formed between the external tube B and an internal tube or thimble D, which is closed at its lower end, and tapers to a larger diameter at its upper end. To the lower part of the thimble there lead several inlets Y for air from outside the outer tube B; these inlets being formed by short tubes crossing the annular passage C. At F (the upper end of the tubes) the mixture of gas and air issues from the annular mouth between them; and this mixture being ignited forms a circular flame, which receives air not only from the outside, but also from the interior of the thimble D, to which the air is admitted by the inlets Y. The upper part of the tube B and of the thimble D may be of metal, as shown. It is generally, however, preferable (says the patentee) to make the parts which are next the flame of steatite or such like material.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

THE IMPERIAL CONTINENTAL GAS ASSOCIATION.

SIR,—The Directors of the Imperial Continental Gas Association, alone (so far as my observation extends) among joint-stock companies, do not send to the shareholders any balance-sheet or report of any kind. All that the shareholders get is a circular, in similar terms to the advertisement which appears to-day, containing the resolutions that a dividend at the rate of 10 per cent. be declared, and that a vote of thanks be given to the Directors and officers. The Chairman no doubt makes a statement at the meeting, giving much interesting information; but, as there must be many hundred shareholders who, like myself, are unable to be present at the meeting, it would be, I should think, a great satisfaction to them to have a report and balance-sheet from which they might see for themselves how their undertaking is progressing. It would certainly be a satisfaction to

Nov. 7, 1888.

A SHAREHOLDER.

[It may be pointed out to our correspondent that the Chairman of the Association has frequently explained at the meetings, in answer to shareholders, that there is a special reason for the non-publication of the particulars mentioned.—ED. J.G.L.]

WATER BY MEASURE.

SIR,—“Meter” has courteously responded to my inquiry in the JOURNAL for the 30th ult., by informing you (*ante*, p. 807) that he is “acquainted with three ‘low-pressure’ water-meters—viz., Parkinson’s, Cowan’s, and the Bascule.” But, as he is still “entirely opposed to a supply of water by meter for domestic purposes,” I may assume that his opposition is based on sanitary and financial reasons rather than on considerations arising out of the merits, or the defects, of any particular meter or class of meter. And yet his references to the notorious defects of most water-meters in common use are indications that he is not wholly uninfluenced by these considerations, and that if a meter free from these defects were forthcoming, he might be induced to reconsider his attitude, and to view the question somewhat differently.

“Meter” says he has found it necessary to be “constantly repairing” water-meters. But he will, in fairness, admit that it is at least possible that there may be meters which it is not necessary to be “constantly repairing;” and, further, that although “Meter” may, in his extended experience, have become “acquainted” with such meters, he may not have had the opportunity of using them, and, therefore, have had no experience regarding them. In like manner, “Meter” may have used only, or chiefly, “high-pressure” meters, which are costly to purchase and expensive and troublesome to keep in repair, and which require repairing very often. He may have had little or no chance of using meters on the “low-pressure” principle, in which these objectionable features are absent. In addition, therefore, to his being “entirely opposed to a supply of water by meter for domestic purposes,” your correspondent adduces objections to such a supply which might conceivably be overcome if the fundamental difficulty could only be removed. For the question is not whether most water-meters are costly to buy and to keep in repair, but rather whether any water-meter is obtainable which, being neither expensive nor likely to go wrong, will do what it has not hitherto been found possible to do satisfactorily and cheaply.

That “low-pressure” meters are, and that “high-pressure” meters are not suited for domestic water measurement is what I am prepared to maintain; and if “Meter” would forget—for the moment, at least—his initial objection to all meter systems, I might hope to convince him of this. Common premisses being necessary, I may fairly ask him to admit that “high-pressure” meters are, generally, incapable of measuring all the water which a cistern ball-valve may pass. Then, taking this for granted, I would ask him, “Why should water be measured at a distance from the cistern, and thereby more or less of it be allowed to pass from the ball-valve unregistered, when, by placing the meter at the cistern, you can measure with perfect accuracy all that passes?”

Your correspondent asks me to explain why a low-pressure meter “ought to be used and fixed over a cistern.” But, as he is “acquainted with three low-pressure meters,” he should be able to answer this question without my assistance. And in regard to his further question, “Why is such a meter and position superior to the present class of meters and methods of fixing?” I think I have already indicated the grounds of the superiority. I am not sure that I agree with him in calling the “new fad demanded by the medical profession, of connecting the drinking-water tap direct from the main,” a “fad;” but, whether it be so or not, the demand could be practically complied with by such a low-pressure meter as I have in view. It is otherwise in the case of “garden supply,” which must be “delivered under pressure.” But ought the fact that *this* “would require another class of meter” to be urged against the use of meters which are the best suited for the measurement of water into cisterns, whether for domestic or for other purposes?

“Meter” says it is “necessary to read water-meters once a month;” and he contends that this would be inconvenient in the case of meters “placed in the roof” of houses. It is not worth while arguing the question of convenience; but I may ask, Why should water-meters be read once a month? Is it not because the meters at present in use are so frequently going wrong that a monthly visit to them is considered necessary? But, though such a necessity may exist in the case of the high-pressure meters used by your correspondent, it would be absent in the case of such meters as I have in view.

Nov. 9, 1888.

TRUE MEASURE.

REDUCTIONS IN PRICE.—The Directors of the *Alresford Gas Company* have decided to reduce the price of gas from 5s. 10d. to 5s. per 1000 cubic feet.—The *Hindley Local Board* adopted last Thursday a joint recommendation of the Gas Committee and the Finance Committee that the price of gas should be reduced on and after Dec. 26 next to 3s. 4d. per 1000 cubic feet, with an allowance of 20 per cent. to large, and 10 per cent. to small consumers, providing the accounts are paid within a month from the end of the quarter. This will leave the net cost of the gas 2s. 8d. to large, and 3s. to small consumers.

Legal Intelligence.

HIGH COURT OF JUSTICE.—CHANCERY DIVISION.

SATURDAY, NOV. 10.

(Before Mr. Justice KAY.)

In re THE PATENT ARGAND GAS AND OIL BURNERS COMPANY, LIMITED.

This was a petition presented by Mr. A. A. Lister, Gas Engineer, of Birmingham, who claimed to be a creditor for £234 16s. 6d., asking for a compulsory winding-up order. The Company was formed to acquire certain inventions for improvements in oil and gas burners, and generally to carry on the business of gas-fitters. The nominal capital was £25,000, in 10,000 shares of £2 10s. each, of which only 362 had been issued. The petitioner was formerly in the employ of the Company, and the debt was for salary, expenses, &c. The debt was not disputed.

Mr. MARTEN, Q.C., who appeared for the petitioner, said the insolvency of the Company was admitted. An extraordinary resolution had been passed for voluntary winding up and the appointment of a liquidator. A compulsory order was asked for by the petition; but he should be content with a supervision order.

Mr. KERLY, on behalf of the Company, submitted that the petition ought to be dismissed with costs, as it had been presented after notice of the voluntary winding up. The petitioner commenced an action for the recovery of his debt, and the Company entered an appearance to the action. The petitioner was informed that the resolution to wind up voluntarily had been passed, and that an independent person had been appointed as liquidator; and he was urged, in the interest of creditors, not to go on with the action. To this he replied that it was not his intention to proceed, but he had issued a petition. Under these circumstances, he (the learned Counsel) submitted that the petitioner had acted with extreme precipitation; and as the majority of the creditors were adverse to a compulsory order, the petition ought to be dismissed.

Mr. MILLAR, Q.C., on behalf of thirteen creditors, whose debts amounted in the aggregate to £3413 2s. 7d. out of a total indebtedness of £4559, objected to a compulsory order being made.

Mr. LEVETT, who appeared for a judgment creditor for £26, asked for a supervision order.

Justice KAY said that as the majority of the creditors objected to a compulsory order, the Court was bound to have regard to their wishes, especially as the petition alleged that the Company was insolvent. As the whole of the property belonged to the creditors, the Court would regard their wishes. He greatly disapproved of what had been done, considering that the petitioner should have stated in his petition that the Company was in course of voluntary liquidation. The petition would be refused, with costs.

HIGH COURT OF JUSTICE.—QUEEN'S BENCH DIVISION.

MONDAY, OCT. 29.

(Before Baron Pollock and Mr. Justice MANISTY.)

CUTLER AND SONS v. KLONNE.

This was a motion on behalf of the plaintiffs in the action, which had been sent to the Official Referee (Mr. Ridley) to dispose of. The Referee had found that sums amounting to £764, £172 0s. 8d., and £76 1s. 5d. (being, in fact, the whole of the plaintiffs' claim, with some slight deductions) were due from the defendant; these being sums claimed under a contract by which the plaintiffs had undertaken to supply and erect a gas-holder at Leyden for the defendant, who was the contractor for the erection of large gas-works for the Corporation of that city. On the other hand, the defendant had a counterclaim for £1025 for penalties, and also for a sum of £217 12s. in respect of payment made by him by direction of the plaintiffs. The Referee had allowed the latter claim, with the exception of £10; but rejected altogether the claim for penalties. He had given the plaintiffs their costs, with the exception of the costs of the counterclaim, as to which he said the defendant was entitled to costs.

Mr. HOUGHTON, who appeared for the plaintiffs, said the entire question was whether the words which the Referee had used really carried out his intention. It appeared to his clients that the finding as it stood would give the defendant the whole costs of the counterclaim, including the portion on which he had failed, which was the substantial question in dispute, and involved great expense in sending expert witnesses to Holland. The real question in the action was whether the delay which undoubtedly took place was due to the action of the plaintiffs or defendant; the plaintiffs' contention being that it was caused first by the defendant not giving them possession of the foundations at the proper time; and, secondly, by his having turned water into the tank too soon, and so caused it to bulge, which necessitated much of the work being done over again.

After some discussion, it was arranged that the Referee should state to the Court the view he had really taken as to the costs, in order to see whether any verbal alterations were required; and the matter was accordingly adjourned for that purpose.

Mr. SPOKES appeared for the defendant, who had presented a cross-motion of appeal, which was abandoned at the bar.

WEDNESDAY, NOV. 7.

To-day, the Official Referee was in attendance, and was asked by the Court, with the consent of the parties, to state his view of how the costs should be dealt with.

Mr. RIDLEY said the counterclaim was divisible into two parts—the most important one being the claim for penalties, and the less important one the claim for work done. Upon the latter claim the defendant succeeded, but failed upon the first. In finding as he had done, he did not intend that the defendant should get the costs of that part of the counterclaim on which he had failed; in fact, it was not present to his mind at the moment that there would be so important a difference with respect to the costs; and he found generally for the counterclaim, because, as the defendant had succeeded on one portion, he (Mr. Ridley) considered there was a right to put the counterclaim on the record. It was not present to his mind that he was finding that the defendant was entitled to the costs of the issue on which he had failed. It would more clearly have expressed his view if he had said that the defendant should have the costs of the issue on the counterclaim on which he had succeeded.

Their Lordships directed that the matter should go back to the Official Referee, in order that he might amend his finding.

BAHIA GAS COMPANY, LIMITED.—The accounts of this Company for the half year ending June 30 last, to be presented at the meeting of shareholders on the 22nd inst., show that the receipts during the six months amounted to £20,155, and the expenditure to £11,949—leaving a balance of £8205. After placing £1000 to the reserve fund, a profit remains of £7205, which, added to the balance brought forward from the last accounts, makes the sum of £8196. The Directors recommend the usual dividends on the preference shares; and a dividend at the rate of 10 per cent. per annum (free of income-tax) on the ordinary shares, which will absorb £7250, and leave a balance of £946 to carry forward.

Miscellaneous News.

IMPERIAL CONTINENTAL GAS ASSOCIATION.

The Half-Yearly General Meeting of this Association was held last Tuesday, at the Cannon Street Hotel—Sir JULIAN GOLDSMID, Bart., M.P., in the chair.

The SECRETARY (Mr. R. S. Gardiner) read the notice convening the meeting, and also the following report of the Directors:—

The present half-yearly ordinary general meeting of the proprietors has been convened in conformity with the Association's Acts of Parliament for the purpose of receiving a report from the Directors upon the affairs of the Company, and of declaring a dividend for the half year ended June 30, 1888.

The following summary shows the results of the Association's operations during that period:—

	Cubic Feet.
The quantity of gas made in the half year ended June 30 last was	3,673,000,000
The quantity made in the corresponding half year of 1887 was	3,670,000,000
Being an increase of	3,000,000

Or at the rate of 0·07 per cent.; but in the corresponding half year of 1887, the Association's former works at Rotterdam and Delfshaven were still in action, and produced 131 million cubic feet.

The quantity of gas sold in the half year under consideration was 3397 million cubic feet—an increase of 51 millions, or at the rate of 1·52 per cent.

The total number of lights on June 30 last amounted to 1,713,121; there being at that date 123,186 consumers on the books of the Association. At the close of the corresponding half year of 1887, the number of lights was 1,678,554. These figures give an increase of 34,567, or at the rate of 2·06 per cent.

The entire length of mains laid on June 30 last was 1339 miles. The length of mains laid on June 30, 1887, was 1461 miles; showing a decrease of 22 miles, which is due to the closing of the works at Rotterdam and Delfshaven, which on June 30, 1887, served together a system of mains 59 miles 203 yards in length.

A comparison of the cost of the coal employed during the half year with that of the coal used in the corresponding period of 1887, exhibits a decrease of 311d. per ton.

There was a slight decrease in the value of coke; but there was a further recovery in that of tar, and the revenue derived from the sale or treatment of ammoniacal liquor also exhibited improvement.

Notwithstanding the loss of the Rotterdam and Delfshaven stations, there was a slight increase both in the rental and in the profit of the half year under review.

The plant and mains at all the stations were maintained in a due state of efficiency. The extensions on the Association's Gitschinerstrasse works at Berlin made further progress, and land was purchased for the extension of the Association's Schoeneberg works at the same station, which has also become necessary. A piece of land was purchased at Schonweide, in the neighbourhood of Berlin, upon which apparatus will be erected for the treatment of the whole of the Ammoniacal Liquor produced on the Association's works at Berlin.

The contract with the Municipality of Aix-la-Chapelle was extended for a period of two and a half years; and an exclusive privilege of the gas supply was obtained for the 21 years which the concession has now to run.

The contract with the Municipality of Hanover was extended for a period of 25 years; and a similar privilege obtained for the remaining 37 years of that concession.

An arrangement was entered into with the Municipality of Antwerp, by which the private consumers have been conceded an important reduction in price, and the onerous conditions upon which the public lighting is supplied have been slightly improved.

The Association's contract with the Commune of Bockenheim—a suburb of Frankfurt—has been extended for a term of 30 years.

Advantage was taken of opportunities which arose of purchasing a small plot of land adjoining the Association's Erberg works at Vienna, and a house adjoining the Association's Central Electric Lighting Station there.

A small property which adjoined the Association's works at Hanover was also purchased.

The Directors desire, in conclusion, to draw the attention of the proprietors to the accounts for the half year ended the 30th of June last. These have been duly audited; and, from them, the Directors have, in accordance with the provisions of the Companies' Clauses Consolidation Act, prepared a scheme showing the profit of the Association for the half year, and the portion thereof applicable for the purposes of dividend, which they recommend now to be declared—viz., a dividend of 5 per cent. for the half year ended June 30 last, payable free of income-tax, on and after the 1st day of December next.

The CHAIRMAN: I have to move that the report be adopted; and perhaps, as far as we are concerned, it might be sufficient if I were simply to do that, because the course of our business has been singularly even, steady, and satisfactory during the six months now under review. Several of us in the course of last winter were abroad upon the business of the Association; and I think every possible attention has been given to it by the Directors, the Agents, and the Engineers, who are all interested in the Association. I can honestly and fairly say that I believe it is in as flourishing and satisfactory a condition as that of any gas company of which I have any knowledge in this country or out of it. We have been fortunate in extending contracts, and in improving our position in several of the towns with which we are connected from a business point of view. Of course, our great desire always is, where we have not a perpetual right, to extend our contracts for as great a length of time as we possibly can. I am afraid that people abroad are rather bitten with the idea which prevails among so many people at home—that corporations can manage gas-works better than companies. Recent scandals, however, of which many of us have read and heard in this country have shown that it is not always the most satisfactory method that can be pursued on behalf of the public, and may, I think, lead some people to pause before they endeavour to push forward this method of absorbing so many important businesses in municipal hands. My opinion is that all municipal bodies can much better look after the serious matters of government with which they have to deal, and leave trading to traders who are accustomed to it, who understand it, and who, when they are looking after their own interests, also consider the interests of the public. As far as our business is concerned, you will see there is a steady improvement, to which I have referred on previous occasions; and I think this improvement is likely to continue, because you will all have noted the more satisfactory condition of trade not only in England, but throughout Europe. The result, of course, is that business men, who were formerly careful of every halfpenny, are obliged to keep their offices and works open longer, and so use more gas; and this, I trust, will improve our business. On the whole, as far as I know, as I said just now, the condition of our business is as satisfactory as you could desire it; and I think there is nothing to be said on the other side of the picture. The only matter to which perhaps I should refer, though it happened since these accounts closed, is that, as many of you are aware, we have completed the electric light installation at the Burg Theatre in Vienna, which is the great new theatre that was opened the other day by the Emperor, about which you have read in the newspapers. We have been complimented on our success by both the Government and the scientific authorities in Vienna. Practically, therefore, you may say that the electric lighting arrangements there are completed; and I believe they give the utmost satisfaction, and do credit to the engineers who have carried them out. This matter, which created a great deal of excitement some months ago, but which has now settled down into the ordinary course of the business, will no longer attract an undue share of attention, because, though eminently successful, it is, as I have said at

previous meetings, a business which we entered into for reasons peculiar to the city of Vienna, and one which was necessary, in order to maintain our position there. Having said so much, I do not think it is essential for me to refer to anything else as to the business in the past half year. I have always, however, made it a practice to say something about any point that may have occurred concerning our affairs since the date of closing the accounts; and to-day I would especially do so, as we have to deplore the loss of several most valuable members of this Association. Only the other day, one of our Auditors, Mr. T. Rowland Hill, after having audited the accounts with his usual care and attention, in conjunction with Mr. Sebag Montefiore, went down to his home at Tunbridge Wells; and within a few days was no more. Though only an Auditor for four or five years, we appreciated his honesty, his straightforwardness, and his desire to promote the interests of the Association. As his death was so recent, I would advise the proprietors not to fill up the vacancy to-day, seeing that a chance has not been given to those who wish to have the opportunity of offering themselves. I would, therefore, advise you to elect a new Auditor on the next occasion, and would suggest that any gentleman who desires to be a candidate should send in his name to the Secretary, in order that due announcement may be made with regard to it. This is eminently a shareholder's post; and therefore I venture to make this suggestion, and I think you will appreciate the spirit in which I do it. Then I have to refer to the death of men long connected with our Association, and who have done us great service for a long time. In the first place, I would refer to one of our late Engineers, Mr. Miltner, who was head of our engineering staff at Amsterdam for many years, and who showed much zeal in the service in which he had grown up, and to which his heart was devoted. In the second place, I would refer to a younger man—Mr. Pazzani—who was also at Amsterdam, and previously at Vienna, and who showed signal energy and ability in the service of the Association. He was taken away from us a few days ago at the age of 47, in the prime of life, and in the fulness of his energy and ability; and I cannot too strongly express the regret we all feel at his premature loss. Well, gentlemen, after all I am happy to say, though we grieve over the departure of men who have done such good service, and to whom many of us were sincerely attached, that we have still able officers well capable of fulfilling any duties that may devolve on them in consequence of their having to replace men who have gone before; and I certainly believe that our service will not suffer, though we have these losses to deplore. Perhaps there is only one other matter I need refer to. I have alluded to the opening of the Burg Theatre on Oct. 14, which was after the closing of this report. I may tell you that we have maintained at Vienna for many years that, whether or not we undertook the public lighting, we had a right, under the Imperial authority which was given to us, to continue for all time to light any private person from the streets of Vienna. Now that proposition has sometimes been disputed; but I think the dispute has never been seriously entertained, because I believe the best Austrian lawyers saw that it would be impossible to do so. But the town authorities some three years ago thought they would try it, and initiated proceedings which involved the discussion of our right to continue permanently to furnish light to the inhabitants of Vienna, even though we did not undertake the public lighting. Our legal advisers—and they were the very best that could be had—told us that, certain as they were our case was an excellent one, they were not always certain that in the lowest courts the decision would be absolutely satisfactory to us, and consequently you can understand how pleased they were the other day when the matter came before the first tribunal for decision, which was absolutely upon every point in favour of the contention we had always held. The matter may no doubt be re-heard on appeal; but I and all those who advise us have no fear as to the result, which, if anything, will tend to strengthen the position we occupy in this most important capital. I may say that, when I was in Vienna last December, I was satisfied, not only that our service was good, but also that our able Engineer, Mr. H. Drory, was prepared to meet every reasonable requirement of the public; and I think we may say that the city is a model to many other cities in different parts of Europe. That is the position of affairs now. I have nothing further to add, except that I am ready to answer any question which may be put to me as far as the interests of the Company will allow it; and I have now to ask you to adopt the report which has been read by the Secretary.

Mr. Wood seconded the resolution.

Mr. GROVER complimented the Chairman and Directors on the very satisfactory report which had been presented to the proprietors. Having regard to the loss of such an important station as Rotterdam and Delfshaven, he considered that the increase of 1·52 per cent. in the quantity of gas sold in the half year was fairly satisfactory. He thought, however, that it was hardly possible for anyone who had shares in gas companies to help feeling that considerable progress was being made at the present time in electric lighting, not only on the Continent but in London. The matter was brought forcibly to his notice a few days ago at his club, where they happened to have some members of the St. Stephen's Club, who had lately decided on expending over £1000 in placing the electric light in their building. At his (the speaker's) club, instead of putting in the electric light, they had improved the gas supply; and some of the members of the Committee of St. Stephen's Club said that if they had only known what could be done with gas, they would not have gone to the expense of installing the electric light. He frequently found that this was the case—that people really did not know what could be accomplished with gas, and what he suggested was that some members of the Board, possibly assisted by some shareholder who had the matter at heart, should endeavour to try and find out some method of popularizing gas by showing the public in the towns which they lighted what gas was able to do in the way of illumination. In most houses bad burners were used; and this caused people to say that it would be a good thing when the electric light did supersede gas. Could not the Directors, he asked, appoint a small Committee, with power, if thought advisable, to offer a reward for the best form of lighting by gas? By doing this, he believed much would be done to popularize the use of gas. No doubt gas companies paid good dividends; but he thought they did not in all respects march with the times.

The CHAIRMAN: If no other shareholder has anything to say, I will reply to Mr. Grover's remarks. We have for years past abroad, where the conditions somewhat differ from what they are in England, done our best to popularize gas. We have, in towns where we considered it would be useful, opened show-rooms of appliances of any value, which are exhibited by our representatives to manufacturers and others; and we have canvassers going about explaining the advantages of gas lighting and all those things which Mr. Grover and we know so well, but which, he says, the public is not so conversant with. We take every possible step we can in this way to increase the business of the Association. In fact, it has never been our practice to adopt the motto of which we have heard in political life—"Rest and be thankful." We are always thankful, but never restful. We are ever endeavouring to increase the volume of our business by every means in our power; and I can assure Mr. Grover and the shareholders that nothing will be wanting in future, as nothing has been wanting in

the past, in our endeavours in this direction. There is, as you know, to be an exhibition in Paris next year; and the gas department of the Exhibition will be an interesting and important one. We are taking our part in it. I think, if Mr. Grover had been aware of all this, he would have said that the Board have not been remiss in these matters, but that, on the contrary, they have done their best to introduce gas among the inhabitants in the towns supplied by the Association.

The motion was carried unanimously.

The CHAIRMAN next proposed the following resolution:—"That a dividend of 5 per cent. for the half year which ended on the 30th of June be now declared on the £3,800,000, stock of this Association; and the same be payable, free of income-tax, on and after Dec. 1 next."

Mr. WOOD seconded the motion, which was unanimously agreed to.

Mr. SEBAG MONTEFIORE proposed a vote of thanks to the Directors, for the careful manner in which they had managed the affairs of the Association during the half year. In doing so, he thanked the Chairman for the kind and graceful way in which he had alluded to the lamented death of his (Mr. Montefiore's) late colleague and co-Auditor, Mr. Hill. He thought the remarks of the Chairman would be very agreeable to the family of the deceased gentleman. He might say that Mr. Hill died almost in the execution of his duty; for, as the Secretary could testify, Mr. Hill was extremely ill on the day on which he audited the accounts. Reverting to his resolution, the speaker said that, having a very large stake in the Company, he had listened, as they all must have done, with great satisfaction to the way in which the Chairman had addressed them regarding the affairs of the Association. He thought all the shareholders might go away from the meeting with increased satisfaction with the position which they had been told by so eminent an authority the Company now occupied.

Mr. A. COOPER seconded the motion, which was carried unanimously.

The CHAIRMAN: I have to thank Mr. Sebag Montefiore for the kind words he has used with respect to myself and the Directors. I can honestly say that, as far as I know, there is no Board every member of which is more prepared to devote what talent and ability he has to the service of his Company than is this Board. I believe that four or five of us have during the last year been on the Continent on the affairs of the Association; and though some of the older ones are not prepared to do this, they are always ready to give us their advice in matters of difficulty or importance that come before us. Nothing encourages us so much as the constant support and confidence which the shareholders show in us; and we are very much obliged to you. I have now to ask you to pass the usual vote of thanks, which is by no means a formality, to our staff abroad, headed by Mr. Drory and Mr. Lindon, and to our staff in London headed by Mr. Gardiner.

Mr. WOOD seconded the motion, observing that he could do so with all sincerity, being acquainted with most of the gentlemen who worked for the Association.

The motion was carried unanimously; and the proceedings then terminated.

BOMBAY GAS COMPANY, LIMITED.

The Half-Yearly General Meeting of this Company was held last Wednesday, at the London Offices, 6, Drapers' Gardens, Throgmorton Avenue—Mr. R. DAVIDSON in the chair.

The SECRETARY (Mr. J. H. Perrins) read the notice convening the meeting, and the Directors' report and accounts for the half year ending June 30 last, which were referred to in the JOURNAL for the 30th ult. (p. 768), were taken as read.

The CHAIRMAN said the accounts spoke very much for themselves; but he would make one or two remarks upon them. The shareholders would see from the report that the revenue from the sale of gas and the rent of meters showed a satisfactory increase of £1102 over the corresponding period of 1887. The receipts from coke, tar, and fittings were also better by £956. The interest account was less, owing to a smaller sum being in Bombay; the money having been remitted to this side by means of bills of exchange. Looking at the debtor side of the profit and loss account, the consumption of coal was 212 tons more (owing to the larger quantity of gas made), which coupled with the fact that higher rates of freight had to be paid, accounted for the increase of £958 in the cost of carbonizing, as compared with the expenditure in the same period of last year. The cost of the coal into the works averaged £1 9s. 5d. per ton, against £1 6s. 10d.—an advance of 2s. 7d. per ton. For many years past the coal had been shipped at a very low price; but it could not be expected that freights would always remain so low, and it would seem probable that in the near future, the coal supplies would stand at an advanced figure. The report also mentioned that on the money brought home during the year there was a loss of £14,974. The rate of exchange was 1s. 4½d.—being the lowest at which the Company had ever had money remitted from Bombay. The declared profits for the year ending June 30 last were £18,960. The shareholders would see that the loss on exchange was equal to 74 per cent. of this amount. He thought there was some little reason for thinking that the money would come home from Bombay during the ensuing year at a slightly better exchange. It was with great regret that the Directors had to announce the resignation, through indisposition, of one of the auditors—Mr. G. A. Northover. He had held the position for the last six years; and the shareholders, he (the Chairman) was sure, would join in the sympathy and regret of the Directors at his enforced retirement. As stated in the report, the Board had elected Mr. E. A. Flinders to fill the vacancy until the next ordinary meeting, when the shareholders would be asked to confirm the appointment. With the exception of the purifiers, the works and plant of the Company were reported to be in good condition at the end of the June half year. Since then four new purifiers, having all the latest improvements, had been sent out, to take the place of the old ones which had been in use since the starting of the Company, and were consequently very antiquated, and almost worn out. The new purifiers would be paid for during the current half year; and this item would therefore appear in the next accounts. In conclusion, he moved the adoption of the report and the statement of accounts.

Mr. W. B. M. LYSLEY seconded the motion.

Mr. BLUNDELL remarked that he did not know that there was much to be said on the shareholders' side of the table. Of course, they all endorsed the observations of the Chairman in regard to Mr. Northover's retirement; and they much regretted the reason which compelled him to resign. He would like to ask what would be the cost of the purifiers that were being sent out. He presumed the Directors would be able to dispose of the old purifiers for some consideration, which would go towards the cost of the new ones.

Mr. HOUGHTON said that he had been a shareholder for nearly 20 years; and he did not find that they had improved very much. The shareholders had always had 7½ per cent. dividend; and he saw that the Company did not make much progress as regards earnings. He had looked over a few of the half-yearly reports; and the money the Company took seemed to increase but very little. Some years ago there was a great scare about the electric light; and much fuss was made in that room, and at other gas

companies' meetings, as to the increased consumption which they would obtain by the use of stoves for cooking and heating. Instead of an advance, however, they seemed to be stationary. The state of exchange, he considered, was rather bogus; and he suggested that they should charge more for the gas in Bombay. They could only judge what the earnings really were by the number of rupees they took; and he would like to know whether the Company had progressed during the past ten years.

Mr. CUFF said, as the Chairman had remarked, the accounts spoke for themselves. On the whole, he thought they were very favourable—especially as regards the bad debts, which he was glad to see, formed so small an item in their accounts. The gentleman who had just spoken alluded to the very slow progress of the Company. He (Mr. Cuff) did not see that they could progress very fast while they were unable to extend their mains. If they were in a position to take in a larger area, then they might expect the receipts to increase faster. However, they were making steady progress. The income was gradually increasing; and if it were not for the wretched exchange, the Board would be able to pay the shareholders a much higher dividend. They seemed now to have settled down, and this loss on exchange was a sort of fixed charge. But, fortunately, the Directors were able to maintain the dividend, notwithstanding this great drawback. There was one question he wished to ask, and that was with reference to the cash in Bombay—whether they reduced this to sterling value when they took it into the accounts. He expressed his regret at Mr. Northover's retirement.

The CHAIRMAN, in reply, said that the loss on exchange was very real; it was not a bogus amount. Ten years ago, in bringing home their money, they lost £2500; while this year the loss amounted to £15,000—and this without having to reduce the dividend. During the year an amount equal to 79 per cent. of the declared profit disappeared in the shape of exchange. The price of gas in Bombay was 6 rupees per 1000 cubic feet. If they were to try to put up the price, the consumption would immediately be seriously affected.

A SHAREHOLDER: Have the earnings in rupees increased in the last ten years?

The CHAIRMAN: Unquestionably, very largely.

Mr. ALFRED PENNY, replying to the inquiry with regard to the purifiers, said that, in a district where there were other gas companies, there were two means of making money out of old purifiers—one was to sell them to another company, and the other to dispose of them for old iron. As there were no other Gas Companies in Bombay, and it would not do to ship the purifiers to England, they had to sell them for old iron, which produced something. Considering the purifiers had been in existence since the formation of the Company, and the consumption of gas had been constantly increasing, it was very remarkable that they had lasted so long. As to the outlay, the new purifiers, including a new roof to cover them, would cost perhaps £1500. The shareholders saw that concurrently with the increase in business there was the diminution in the money received for the rupee. This was their great drawback. He might perhaps say that, supposing the value of the rupee had continued at 2s., they would long before this have been obliged to reduce the price of gas, which they would have been very pleased to have done, to increase the consumption. Owing to the loss they sustained every year, they could not do this. The increase in the business, however, enabled them to keep up the dividend. They obtained a fair profit out of the sale of gas; and the more gas they could sell, the less it would cost to make. But the business did not increase so fast as to beat the enemy they had in this low rate of exchange. They were, however, constantly watching every point to economize the working; and he was very glad that they had succeeded so far—notwithstanding that they lost more money by the remittances to England than they had done in any former year—in keeping up the dividend by the constant increase in business, which had been remarkable in the last three years.

The CHAIRMAN observed that in 1876 the gas sold for private lighting was 20,384,000 cubic feet; and last year it amounted to 32,720,000 feet. This showed their progress; but the loss on exchange came in, and took it away. Replying to one of Mr. Cuff's questions, he said that the cash was brought home to a point every year; and they did not leave money in Bombay. It only remained there for a time to catch the rate of exchange; and as soon as they thought it was favourable, the money came home.

The motion was then carried unanimously.

On the proposition of Mr. R. KING, seconded by Mr. CUFF, a vote of thanks was accorded to the Chairman and Directors, for their attention to the Company's business during the half year.

The CHAIRMAN having replied, the proceedings terminated.

GEORGETOWN (BRITISH GUIANA) GAS COMPANY, LIMITED.

The Ordinary Half-Yearly Meeting of this Company was held last Tuesday, at the London Offices, 30, Gracechurch Street—Mr. ALFRED WILLIAMS in the chair.

The SECRETARY (Mr. Alfred Lass, F.C.A.) read the notice convening the meeting; and it was agreed to take as read the report and accounts, which were summarized in the JOURNAL for the 30th ult. (p. 765).

The CHAIRMAN said that the report and accounts had been sent to all the shareholders; and he would be glad to answer any questions which they chose to put to him in regard to them. To his mind, they were very satisfactory; and he would, without further remark, move—"That the report and accounts be received and adopted, and entered on the minutes."

Mr. C. GANDON seconded the motion, which was at once unanimously agreed to.

The CHAIRMAN then moved the declaration of a dividend for the half year ended June 30 last on the preference share capital at the rate of 8 per cent. per annum; and on the ordinary share capital at the rate of 7 per cent. per annum, both less income-tax (except upon those dividends to which the local shareholders are entitled), payable on Dec. 1 next.

Mr. C. NEWTON seconded the motion, which was carried.

The CHAIRMAN proposed a vote of thanks to the Local Committee in Georgetown, the Secretary (Mr. A. Lass), the Local Secretary (Mr. F. A. Conyers), the Engineer and Manager (Mr. T. B. Younger), the Auditors (Messrs. R. King and C. Newton), and the Solicitor (Mr. E. K. Blyth), for their services during the past half year. He expressed the hope that these gentlemen would continue to merit and receive the thanks of the shareholders at many future half-yearly meetings.

Mr. GANDON seconded the proposal, which was heartily approved.

Mr. R. KING briefly acknowledged the vote on behalf of all mentioned in the resolution.

Mr. BLYTH said they ought to return the compliment by passing a vote of thanks to those who kept the Company such a steady dividend-paying concern.

Mr. KING seconded the motion, and it was agreed to.

The CHAIRMAN, on behalf of himself and his colleagues, thanked the shareholders for their appreciation of the services of the Directors. If they enjoyed health and the confidence of the shareholders, they would do their utmost to keep the Company a "dividend-paying concern."

WEST MIDDLESEX WATER-WORKS COMPANY.

The Half-Yearly General Assembly of the proprietors in this Company was held last Tuesday, at the Offices, 19, Marylebone Road—Sir W. H. WYATT in the chair.

The SECRETARY (Mr. G. B. Hall) read the notice convening the meeting; and the report of the Directors, the chief features of which will be found in the Chairman's remarks in moving its adoption, having been taken as read, he read the report of the Auditors (Messrs. Cumberlege, Mackinnon, and Selby), which stated that the gross rental for the half year ended at Michaelmas last was £109,525; being an increase, as compared with the corresponding period of last year, of £741. The balance to the credit of the dividend and interest account was £134,279.

The CHAIRMAN, in moving the adoption of the report, said he was afraid it would not be in his power to enlighten the proprietors much beyond what they found in the report and the accounts. He would, however, just make a few remarks; and then, if any gentleman wished for further information, the Directors would, as far as they were able, furnish it. In the first place, he was glad to inform them that the new works which were reported upon at their meeting last May were now completed; and they had every reason to hope that the new Worthington engine erected at Molesey would prove a success. It was thought that it would give them greatly increased pumping power, and at a less cost for fuel, than the old ones had ever done before. It would therefore be advantageous in all ways. In the second paragraph of the report, the Directors mentioned that they had bought a piece of land, 4 acres in extent, at Willesden. This ground had cost £1000 an acre, which seemed a high price; and no doubt it was higher than in the ordinary course of things it would be worth. It was, however, just the level which the Company wanted; and they could not get the land for less. They therefore felt bound to acquire it. This would be a large part of the outlay they would make on the reservoir, which would cost possibly £25,000. They would not get any direct return from it—no extra water-rates. But it would enable them to supply the new district with much greater ease and facility; and they thought it best to give the public all the convenience they could. This outlay, therefore, was a serious one; and not only was it serious in the immediate cost, but, unfortunately, the moment they carried out any works of this kind, they were rated at such an extraordinary amount that it entailed on the Company a large annual expenditure. Still, he hoped the proprietors would agree with the Board that it was the best thing for them to do. They were very careful now about spending capital, as they were getting near the end of it. They had only £50,000 left, besides what they had in hand; but they had enough in hand to finish all the works he had mentioned. Still, they had not very much; and they did not wish to go to Parliament for more before they were obliged to do so. Parliament now put such onerous terms on water companies that there was no inducement to apply to it unless they were compelled. He was sorry to say that during the last six months death had been busy among them. They had lost an old and valued Director—Mr. Ware—who had been a member of the Board for 27 years, and who had always done his best for the Company's interests. They had also lost their valued friend and Solicitor Mr. Bailey, who was taken away very suddenly after only a few days' illness; and he (the Chairman) was sure the Directors felt it was only right for him to bear testimony on their behalf to the kindness and care with which Mr. Bailey had always espoused the Company's interests. They very much regretted his removal. Last half year he had to announce a very sad loss for them—the death of their excellent Engineer, Mr. Thomas Hack. They told the proprietors then that they were trying to make arrangements to supply this gentleman's place, and that it was a matter of serious anxiety to them. They had appointed Mr. Matthew W. Hervey, who was for nine years Mr. Hack's assistant; and they had every reason to believe that this would be a very satisfactory appointment. He did not for a moment mean to say that Mr. Hack's death would not be a great loss to the Company, as he had a long and intimate knowledge of their affairs—an advantage which could only be replaced by his successor having a similarly long acquaintance with them. They had associated with Mr. Hervey, as Consultant Engineer, the late Mr. Hack's brother, who was Engineer of the Chelsea Water Company. It was thought by so doing they would have someone else to resort to in case of difficulty; and they had appointed two gentlemen who were in the Company's service to be Assistant Engineers, upon both of whom they could thoroughly rely. He hoped the proprietors would approve and confirm all that the Directors had done in these matters. Then they came to the difficulty as to passing the accounts last time. They still thought they were right in what they did in making the agreement with the Thames Conservators; but Mr. Stonham, the Official Auditor, would not give way, and they had had to go to the cost of a reference. They selected as Arbitrator Sir Henry James, who heard the case on the previous Saturday, but had not yet given his decision. He (the Chairman) could not, of course, say what this would be; but it would not make much difference to the Company. If it was decided that they were not to pay the sum in question, he supposed they would not pay it for some time. But no doubt the Conservators would go to Parliament, and get the Company to pay it; and they did not wish to be released from paying it. On the contrary, they had done everything they could to have the agreement they had entered into, and to which they were bound in honour, confirmed. He concluded by moving—"That the report of the Directors, with the half-yearly accounts, and the report of the Company's Auditors thereon, be severally received, confirmed, and entered on the minutes."

The DEPUTY-CHAIRMAN (Mr. J. Meyer) seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by the DEPUTY-CHAIRMAN, a resolution was passed declaring a dividend for the half year at the rate of 10 per cent. per annum on the consolidated stock.

Votes of thanks were then accorded to the Auditors, for their careful examination of the Company's accounts; as well as to the Directors, for their attention to the affairs of the Company during the half year.

The meeting was then made special for the election of a Director in the place of Mr. Ware.

The SECRETARY read a report of the Directors on the subject, in which they said that notices had been received from Mr. Edward Cumberlege, Mr. Ebenezer Homan, and Mr. Harry Bodkin Poland, three duly qualified proprietors, signifying their intention to be put in nomination for the vacant office. Subsequently Mr. Poland and Mr. Homan withdrew their names, and Mr. Cumberlege was the only proprietor eligible for election.

The Rev. S. P. CUMBERLEGE proposed, and Mr. Homan seconded, a resolution appointing Mr. Cumberlege to the vacant office; and the motion was carried unanimously.

Mr. CUMBERLEGE briefly acknowledged his election; assuring the proprietors that he would use his utmost endeavour to promote the welfare of the Company.

THE PRICE OF COKE.—The demand for gas coke is now growing so rapidly, that some of the northern gas companies who have large sales with cement makers, &c., have advanced their figures. At Stockton the price has been increased to 10s. per ton.

STRIKE AT THE LEITH GAS-WORKS.

The strike of workmen at the Leith Gas-Works, threatened last week, has unfortunately begun. As soon as it was intimated to the Gas Commissioners that this act was contemplated, they issued advertisements warning consumers of their Leith gas that, owing to the conduct of the workmen there, irregularity of supply might possibly arise for a few days. The advertisement continued: "These men demanded certain concessions as to working hours and wages. The Works Committee of the Commissioners, at a meeting on Friday last (the 2nd inst.), agreed to recommend the increase of wages asked for by the retort-house men, and to call a further meeting to consider carefully the claims of the other classes of workmen. This was at once communicated to the men, who, including the retort-house men, have nevertheless banded themselves together, and have given notice that they will leave work on Friday first (9th inst.), unless their demands are immediately conceded. This is intended to concuss the Commissioners into granting demands which they have had no opportunity properly to consider, by the threat of putting a stop to the supply of gas to the public. The Commissioners are resolved to withstand to the utmost such unreasonable and arbitrary conduct, and to dispense with the services of men so acting; and they confidently appeal to the consumers of gas for their forbearance and assistance in meeting any temporary difficulty which may arise." To this the men, speaking through "A Gas Employé," made the following reply through the local press: "In answer to an advertisement in the papers from the Gas Commissioners' Clerk of an entirely misleading character, will you allow me a few lines to correct the glaring misstatements? It says these men demanded certain concessions as to working hours and wages, and that the Works Committee agreed to recommend the increase asked by the retort-men, and that this was at once communicated to the men. But this notice of the rise to the retort-men was not communicated till after they had all given in their notice to drop work at the end of eight days, unless they were put on an equal footing with the Edinburgh men; and after they got the Commissioners' increase on the Friday night, they only continued their agreement with their fellow-workmen to stand by their petition as intimated to the Commissioners. Now what is concussing the Commissioners into granting demands they have had no opportunity properly to consider? It is now about nine weeks since the men petitioned the Commissioners to get their grievances rectified. Surely that was time enough for consideration before the strike was threatened. And the workmen's 'unreasonable and arbitrary conduct,' it seems, is asking to be put on the same footing as the gasmen in Edinburgh, and to get back what was taken off their pay about two years ago." The petition of the retort-men was, they say, to have their wages raised from 6d. to 6½d. per hour. They also state, further, that barrow-men in Leith are paid 23s. 4d. a week of 56 hours, while the Edinburgh men receive 25s. 8d. The men employed on the streets in Leith receive 4d. per hour, and their Edinburgh brethren 5d.; the former working ten hours and the latter nine. At Leith the yardmen get 4d. per hour, while in Edinburgh 5d. is paid; and those employed at the purifiers receive 4d. an hour in Leith and 5½d. in Edinburgh. This statement having been published, an individual Commissioner communicated the following to a press representative on Thursday: "The first petition from the men asking back the reduction that was taken from them two years ago meant a total sum of £395. The Commissioners hold that they offered to give effect to that petition. The second petition, however, requests that all the men should be put on an equality of wage and time with the men in the Edinburgh works. This means something like a sum of £2500 in hours and wages. The Commissioners hold that the men were content to work for the private Company at their present wage, that they ought to have applied to them for an increase, and that there is no change in the circumstances to warrant the demand being made now. Moreover, if they had received the increase, involving £2500, from the private Company, the Commissioners would have had to pay £2500 less of profits to the Company. The Commissioners resolved also to employ workmen from the Edinburgh works as far as possible." The Leith workmen held a meeting last Thursday night, and unanimously resolved to keep to their resolution to strike unless their demands were granted.

On Friday the struggle began. In the forenoon a reporter was informed by the men that that morning the coal-breakers were offered an increase of 3d. per hour on a nine hours' day; and the engine-men a day of eight hours; the question of wages to be considered. These offers were not accepted. At that time the men were confident of success. The workmen, they stated, who had been engaged to succeed them consisted of tailors, joiners, and men of no trade at all, all of whom knew nothing of the labour in gas-works. The men said they had never presented two petitions; that what was called the second petition was merely more detailed information which the Commissioners expressed a desire to have. They repudiated any idea of trying to force the Commissioners to grant their request. At two o'clock in the afternoon the retort-men, who number about 70, stopped work. The shift which should have gone on at that time were waiting outside to see their fellow-workmen come out; but there was no demonstration of any kind—the men preserving a very quiet demeanour. According to their statement, the Commission had not been able to get a sufficient number of men to succeed them; and, instead of keeping 24 settings of retorts going, they said it would take them all their time to keep four at work. At six o'clock all the workmen received their pay; and the remainder of the men—making the number up to nearly 200—then struck. The mechanics have not come out; but they sympathize with their fellow-workmen. On Friday night a picket of the workmen on strike paraded in the vicinity of the works, with the intention of explaining their position to anyone who might appear at the works seeking employment. One of their number, named John McCabe, while under the influence of liquor, approached one of the men (Alexander Walker) who had gone into the works, while he was going for supper, seized him, and warned him not to go back to the works. A charge was made against McCabe, and he was arrested. At the Leith Police Court on Saturday morning—Baillie Archibald, one of the Commissioners, on the bench—he was charged with assaulting Walker. He at first pleaded guilty; but afterwards withdrew it. Evidence having been given, McCabe was fined 15s., with the alternative of ten days' imprisonment. A meeting of the men was held later on, when a resolution was unanimously adopted to the effect that any man resorting to intimidation would do so at his own risk, and that the body of the men condemned such action. The meeting also expressed the hope that the Edinburgh men would keep away during the strike, "and show their manliness towards their fellow-workmen."

CHECKING THE WASTE OF WATER AT BATH.—At the annual meeting of the Bath Corporation Water Committee last Thursday, the Engineer (Mr. Gilby) reported that when the Deacon waste-water meters were first applied the average daily consumption per head was 42.3 gallons; by September last it was reduced to 22.9 gallons; and in October it was 21.8 gallons. This was due to the reduction of the quantity of water wasted, and not to any fluctuation in the consumption.

[THE PURIFICATION OF GAS AT THE DUNDEE GAS-WORKS.]

Our readers will probably remember that references have lately been made by our Edinburgh Correspondent to complaints which have appeared in the Dundee papers as to the quality of the gas supplied by the Corporation. The matter was specially reported upon by the Gas Engineer and Manager (Mr. John McCrae) at the meeting of the Works Committee of the Gas Commissioners on Monday last week. He first explained that in the year 1882 he received instructions that the illuminating power of the gas should be maintained as nearly as possible at 26 candles; and that since that time the instructions had been most carefully and rigidly carried out. The testing apparatus had been kept in perfect order; and those who manipulated it had had large experience in this department. The tests at the works had also been verified by others made in the Sanitary Inspector's office. He then proceeded to deal with the statement that "air is being pumped into the gas at the works." In doing so he traced the steps which led to the adoption of Professor Wanklyn's system of purification at Tunbridge Wells, and subsequently at the Dundee Gas-Works, where it has been in use for the past two and a half years. He next described the process as follows:—"A 2-inch pipe is connected to a meter and to the gas-pipe immediately after it leaves the hydraulic main. At this point the product from the coal is not one gas, but a mixture of many gases, and these at a high temperature. Some of these gases and vapours are condensable, and very rapidly assume the liquid form, as tar and ammoniacal liquor. Contained amongst these tarry vapours is a valuable proportion of rich or light-giving hydrocarbons, and which by the old process were allowed to condense—pass away with the tar, thereby enriching the naphtha, which was later on to be distilled from it. By the admission of this 1 per cent. of air at the point indicated, a good percentage of these hydrocarbons is picked up, carried forward, and becomes a permanent gas; thereby having no depreciating effect on the illuminating power." He then went on to say: "Of course, it will be apparent from what I have said that the quality of the naphtha must be reduced; and that is exactly what we have experienced. But this is of little or no importance, bearing in mind the very low price this product has reached. In a word, we have removed a valuable ingredient from the naphtha, for which we are receiving little or nothing, and converted it into an illuminating gas of good quality, which I consider should be our primary object. Our secondary products, being such, deserve only secondary consideration. Perhaps the most valuable virtue exerted by this 1 per cent. of air lies in the effect on the purification of the gas, for by its introduction the revivifying of the oxide of iron is accomplished *in situ*; thereby rendering the frequent removing of that material from the purifiers unnecessary—a fact which is most interesting and valuable, as will be seen later. I have now described somewhat in detail the process as applied in your works. It is simple, economical, satisfactory, and can be stopped in one minute. Before this air process was introduced, during the summer months there would be a purifier changed at least once a week, and sometimes oftener. During the past summer there was not a purifier opened from the month of April till the month of August; and the gas was thoroughly purified all the time. I think the importance of this point cannot be over-estimated; for, although it may not be a statutory obligation, it is none the less our duty to disturb or annoy as little as possible those outside our works by the processes employed or carried on inside the works." With regard to the personal remarks made in the correspondence above referred to, Mr. McCrae said he would not deign to notice them. He said he had been nearly eight years in charge of the works, and could safely say that, during this period, whatever had been done was to the best of his knowledge for the improvement and modernizing of the plant, the production of good and cheap gas, and the satisfaction alike of the Corporation and the gas consumers of Dundee.

At the Monthly Meeting of the Gas Commissioners on Thursday, reference was made to Mr. McCrae's report. Mr. Lindsay pointed out that the introduction of air was not to dilute the gas—it was to assist in its purification, and to save the money of the Commissioners. It did not bring down the illuminating power of the gas by the fraction of a candle; and Mr. McCrae was quite willing to explain the process. Bailie Macdonald thought the public should be led to clearly understand that the Gas Engineer and the Commission could have no possible motive in diluting the gas. Mr. McCrae had adopted the new plan because he was convinced, by his experience, that it was the best way of purifying the gas. Bailie Gentle remarked that no one had any doubt as to Mr. McCrae's ability as a gas engineer, and that he was doing his utmost to produce the highest quality of gas at the lowest possible cost. He was satisfied with the tests made at the gas-works as well as at the Sanitary Office, which showed that the quality of the gas was kept up to a good standard. It was eventually resolved that the Clerk should communicate with the Local Authorities of certain towns, with the view of obtaining information as to the process.

THE FINANCES OF THE SALFORD CORPORATION GAS DEPARTMENT.

THE BOROUGH AUDITOR ON THE DEPRECIATION AND REDEMPTION FUNDS. An abstract of the Treasurer's accounts of the borough of Salford for the year ending March 25 last has lately been issued. Accompanying it is a letter from the Borough Auditor (Mr. W. J. Popplewell), in which he makes some remarks on the subject of the depreciation and redemption funds of the gas undertaking. The gross profits of the gas fund—£61,525 2s. 9d.—he says, show an increase on the previous year of £5459 10s. 6d. This is augmented by a reduction in the amount of interest paid of £503 6s. 10d.; making altogether £5962 17s. 4d. From this amount has to be deducted a large increase in the sum transferred to the depreciation fund of £4992 5s. 8d., and £168 0s. 1d. increase in the contribution to the redemption fund—together £5160 5s. 9d.—leaving the amount of net profit divisible between the three districts of Salford, Broughton, and Pendleton, only £802 11s. 7d. in excess of the amount divided last year. The first thing which calls for serious notice in this fund, he goes on to remark, is the condition of the depreciation account—a matter recently raised in the public press. As some misapprehension appears to exist on the subject, the Auditor points out the distinction between a depreciation fund and a sinking fund. The putting aside of an annual contribution to a sinking fund for redemption of debt, he says, is a compliance with the conditions imposed when the loans for capital expenditure are authorized, and cannot be evaded, and is intended to provide for the gradual and ultimate extinction of the debt. It does not in any way contribute to the object for which a depreciation fund is formed, which is to provide a fund out of which may be made the replacements and repairs necessary to maintain in efficient condition the works upon which the money borrowed had been expended. While it is certainly incumbent to provide a depreciation fund, it is, on the other hand, equally incumbent that no more shall be taken out of the profits for such purpose than is actually required. And it is quite evident there is no intention that large accumulations shall be made out of profits to provide for future extensions or the erection of new works. There is, however, at the present time, at Salford, an accumulation on account of

nearly £78,000, which is increasing at the rate of £9000 per annum, after fully providing for the objects named in the Corporations' Improvement Act of 1862. This large accumulation has arisen partly through an excessive percentage having been set aside in the past, and partly through the wrongful addition to the fund of the interest earned upon it, which ought rightly to have been credited to the general profit and loss account instead. He gives the following figures to show how largely in excess of the legitimate needs of the fund is the amount set aside:—In the year ending March 31, 1888, the amount set aside for depreciation on works and plant, at 3 per cent., was £14,575 4s.; the interest on the fund for the year was £1935 2s. 10d.—making a total addition of £16,510 6s. 10d.; the average annual expenditure for the past ten years has been £7233 15s. 4d.; or an amount in excess of £9276 11s. 6d. The actual expenditure for the year was only £3771 2s. 3d. Mr. Popplewell does not wish to be understood as objecting to a reasonable surplus over estimated requirements being set aside, or to the retention of even the present large balance in hand, although it is a question whether the sum of the accumulated interest should not be restored to the general fund, and divided between the districts. At any rate, the interest should no longer be added to the depreciation fund; and he recommends most strongly that for the future a reduction of at least 1 per cent. be made on the percentage set aside. The same remarks will apply to the hired meters depreciation fund, in a greater degree perhaps as to the accumulation, but in a lesser degree as to the annual percentage. In this way the saving on the year's figures would be as follows:—General depreciation, 1 per cent., £4858 8s.; interest, £1935 2s. 10d.; hired meters depreciation, at 1 per cent., £383 5s. 9d.; interest, £259 2s. 8d.—making altogether a sum of £7435 18s. 3d. to add to the balance of profit at the disposal of the Committee. In considering this matter, Mr. Popplewell says it should not be overlooked that in addition to the amount set aside for depreciation, a sum of more than £11,000 has been expended on repairs, and charged to revenue account, or over 2 per cent. on the capital invested in works, plant, mains, and services; and he is not sure whether a strict rendering of the Act would not require a large part of this expenditure to be taken out of the depreciation fund, which is limited, as already stated, to 3 per cent. The alterations he recommends in the depreciation accounts are, he thinks, desirable, not only in the interests of those entitled to the benefits of and increase in the profits divisible, but also for the purpose of discouraging extravagant expenditure in extensions under cover of this fund.

As to the revenue account, Mr. Popplewell considers it would be advisable in future that fuller details of some of the items of expenditure should be given; as, for instance, under the heading "manufacture of gas," the amounts paid respectively for coal and cannel, wages, &c.; the present arrangement of the account being retained, as that is desired for tabulation and comparison with the gas accounts published by other corporations and gas companies.

On the subject of the book-keeping of the Gas Department, he says that, although the portion relating to wages, stock, &c., and the checking of invoices, seems to be done in a most thorough and painstaking manner, there is one point which appears to be eminently unsatisfactory, and to which he called attention in his report of last year to the Gas Investigation Committee. The coal and cannel stock book is carefully entered up, so far as the quantities received are concerned, and a balance-sheet prepared; but the result is of little value, for although elaborately prepared figures of the quantities of coal and cannel carbonized are given, there is a large discrepancy between these figures and the total quantity of coal and cannel apparently carbonized, as shown by the measured stocks in hand at the end of the year. The discrepancy this year at one of the stations is 2821 tons, or 5.65 per cent. on the figures in the carbonization book. This means either that those figures are altogether unreliable, or that this quantity of coal and cannel has been disposed of in some other way. The Auditor is inclined to attribute it to the first-named cause; for the figures in the books, although ostensibly received from the different foremen, are, he says, evidently mere estimates; and he suggests, that if it is worth while to employ clerks to prepare elaborate figures of the quantity of material carbonized, it would be a simple and easy matter—if the actual weights cannot be given in every case—to test the estimated quantity at frequent intervals, and so prove satisfactorily that the coal, &c., is really accounted for, or otherwise. The plan adopted, so far as the principal books of the Corporation are concerned, although capable of improvement in some minor points, is, Mr. Popplewell says, well calculated to secure an accurate record of the financial transactions of the Corporation, and, on the whole, works well.

GAS AND THE "RESURRECTION" OF ELECTRIC LIGHTING.

[From *Money*, Nov. 7.]

It is now seven years since the electric light "boom" first excited the alarm of gas shareholders; and during all these years the new illuminant has been passing through the experimental stage, and nothing more. When the "boom" began, we alone amongst financial journals did our best to reassure the terrified gas shareholders; and events have proved how completely we were justified in all that we said. Gas stocks are now higher and safer and pay bigger dividends than ever; and we feel convinced they will continue so for many years to come, notwithstanding that the electric light is at last emerging from the experimental stage, after having impoverished so many hundreds of investors and enriched so many company promoters. We have never desired to depreciate any promising venture. When we wrote down electricity, we did so because we knew that, whatever might be the case in the future, the time of the electric light was not yet, and also because the companies that were formed were all, or nearly all, essentially of the "bubble" order, and not intended to become commercially successful. And now, when there appears to be a fair prospect of success for the new illuminant, we should be the last to attempt to discount that prospect. We have therefore made it our business to inquire into the position of the London Electric Supply Corporation, Limited, of which a good deal has recently been written; and we have come to the conclusion that if ever the electric light is to be a commercial success, it should be so in the hands of this concern. This is not the place to give the history of the Corporation, which is the outcome of Sir Coutts Lindsay's experiment of four years back in lighting the Grosvenor Gallery by electricity; but it may be remarked that the demands made upon the Grosvenor station, which was then installed, have increased so steadily that the present Corporation has been formed, with an authorized capital of £1,000,000, to erect and equip the new central station at Deptford, from which the Directors expect eventually to be in a position to supply the necessary current for 2 million lamps, while they have already invited orders for the supply of electric current for execution early next year.

Let us now consider how the success of this Corporation will affect the very large community of gas shareholders. It has, as usual under like circumstances, been pretty freely stated that if the Corporation is a complete success, gas is doomed; and it is pretty certain that the installation at Deptford will be made a peg upon which to hang "bear" attacks upon

gas stocks. We ourselves, with a full knowledge of the whole position, must counsel holders of gas to fear nothing. If they should allow themselves to be terrified into parting with their stocks, they will certainly have cause to repent doing so. It has been, and still is in some quarters, the fashion to speak of gas and electricity as rivals. They are in reality nothing of the kind. Even if the London Electric Supply Corporation prove to be all the success that its Directors anticipate, we believe that gas will in no way suffer commercially on that account. In the first place, electricity will not, under any circumstances, generally supersede gas as a popular illuminant for some time to come. It is still expensive compared to gas; the proposed charge being 7½d. per Board of Trade unit, which is equal to gas at about 4s. 2d. per 1000 cubic feet. This is a very high rate compared to the present cost of gas; and it is to be noted that The Gaslight and Coke Company have resolved to reduce their rate to 2s. 6d. per 1000 feet for ordinary gas from the beginning of the new year, which reduction will certainly increase their receipts in spite of all competition. But this is not all. The Electric Supply Corporation requires a *guaranteed minimum rental* of £20 per annum in all cases. This requirement alone—necessary as it is—will prevent competition with gas in the case of many thousands of householders whose gas-rate does not reach more than £10 or £15 per annum. Again, the Corporation will charge 20s. a year for rent of meter, against about 8s. charged by the gas companies; and there will be extras for transformers, switches, and extra lamps. So much for the comparison between the "rivals" on the score of cost.

This is a large order, and some particulars of the Corporation and its position will be found interesting. Of the nominal capital of £1,000,000, in £5 shares, rather more than half is at present subscribed; the precise figures being £535,000. The Company is by no means a public company in the full sense of the word, for more than four-fifths of the capital subscribed has been found by an inner ring of eight-and-twenty financiers. These are headed by Lord Wantage, who alone holds not far short of a quarter of a million's worth of these shares. After him come seven holders who have subscribed for 21,752 shares; then fifteen who have taken 23,833 shares; and, finally, five others who hold amongst them 2766 shares. Besides Lord Wantage's £220,000, therefore, no less than £241,755 have been found by twenty-seven other holders. There are in all fifty shareholders, about twenty of whom have subscribed the balance of about £78,000 amongst them. And it is this small but rich syndicate which proposes, taking the requirements of London to be equivalent to 7 million 10-candle power lamps, to light more than a quarter of the Metropolis. Whether or not the Deptford station will be found able to accomplish it, we do not pretend to predict; but it is, we think, pretty clear that this latest and biggest departure in electric lighting will be either a huge success or else a gigantic failure. The Corporation believe the former, as is shown by the sums its handful of members have staked; and if it is a success, they will reap the reward of their courage. If it is a failure, the loss will also be theirs; and in no case will the public share either in the loss or in the profit, unless there should be by-and-by a Stock Exchange "rig" in these shares, as there was in Father Brush and the other old companies. This is generally the way. The public money has already been lost by hundreds of thousands. Now the enterprising financiers step in and reap what profit may be earned.

But the main facts upon which we base our opinion that gas will continue its successful career are very different from the above. The most experienced authorities in the gas world—those who know best and who have the best knowledge of the facts—are agreed that the consumption of gas is not only not likely to decrease generally, but is certain to increase. It is a fact that in almost every place where electricity has been utilized as an illuminant—such as railway stations, factories, shops, &c.—the consumption of gas has not diminished. This is apparently paradoxical; but it is a fact proved by experience. The gas companies may lose the custom of the theatres, hotels, and clubs; but their loss is generally counterbalanced by a very satisfactory increase of consumption in other ways. This is due to the fact that gas may be, and is, daily more and more utilized for many purposes—such as cooking, heating, driving gas-engines, &c.—for which electricity is totally inapplicable. And the uses for gas are increasing far more rapidly than the general use of the electric light is likely to come about; and with the promised reduction in the price of gas, this fact cannot fail to become more and more evident. And here we would remind gas shareholders that the disturbance in the coal trade cannot affect their stock, since the gas companies are well ahead with their contracts, made when coal was at its lowest, as far as the summer of 1890. The rise in the price of coal, so far from being a disadvantage to the gas companies, is actually a source of profit to them; for it is enabling them to get better prices for coke which they have to dispose of.

There yet remains to be considered the important question of residuals. Not long ago the bye-products of a gas company were not only not profitable, but were an actual expense to get rid of as waste. Now they are all utilized. Tar and sulphate of ammonia are now both saleable products; and their prices are steadily rising in the market. And it must be remembered that the quantities of these bye-products are so enormous that a very small rise in price per ton means a very considerable increase in income to the companies. On the whole question, it is hardly stating too much to say that a well-managed gas company can now almost pay its way by the sale of residuals; its income from consumers being therefore almost entirely clear profit.

Thus, so far, then, from anticipating loss, shareholders in The Gaslight and Coke Company may safely anticipate an increase in the capital value of their holdings during next year. For by their statutory sliding scale the Company will be enabled, by its reduction in the price of gas, to pay higher dividends. The 3d. per 1000 cubic feet which is to be deducted from the cost next January will allow an additional ¾ per cent. dividend to be paid on the stock, if it be earned, as no doubt it will be. The Company have a very large balance to draw upon for temporary purposes; and there is, in addition to all this, some prospect of the early abolition of the coal dues, which would mean a saving of something like £90,000 per annum to this Company alone. For all which reasons it is clear that gas shareholders should be of good cheer, in spite of all that electric light "bulls" and gas "bears" may say or do to the contrary.

RETFORD CORPORATION GAS SUPPLY.—The annual report of the Retford Corporation Gas Committee shows that there was an addition to the capital account in the first half of the present year of £402 4s. 8d., principally for new works, which leaves the capital account over-expended by the sum of £2694 2s. 2d. This is provided for by the reserve fund, standing in the books of the undertaking at £3000. The sale of gas during the year has realized £5294 13s. 11d., as against £5298 7s. 1d. in the preceding year; while the quantity made has been 38,730,000 feet, against 38,248,000 feet. After paying interest on debentures, adding to the sinking fund, and paying bank interest and commission, the net profit for the year has been £366 6s. 4d. The expenditure for lighting the public lamps is greater than the amount paid.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The whirl of the municipal elections is over; and a few reflections upon them may not be uninteresting. Beginning nearest home, the first thing which I notice is that Mr. Colston, who took the lead in the negotiations for the purchase of the Edinburgh and Leith gas undertakings, was proposed for the office of Lord Provost of Edinburgh at a private meeting of the Town Council yesterday, but was not elected; his support only numbering 19 votes, as against 21 for his opponent, Mr. Treasurer Boyd. The loss of the office must be a great disappointment to Mr. Colston; this being the fourth time he had entered into a contest for the honour. The strongest arrow in his quiver on this occasion was the part he took in bringing about the transfer of the Gas Companies' property. The proceedings being in private, it is impossible to say what may have been the reasons which the majority of the Council had for rejecting Mr. Colston; but outside observations point to a certain diplomatic subtlety in his actions, which makes it often difficult to say "where" he is on a question. Everybody has not subscribed to the dictum which was laid down by the promoters of the gas transfer themselves, that it was "so successfully" carried through; and it may be that that which Mr. Colston relied upon as his strongest support was, as a matter of fact, his weakest.

In Arbroath the electors have returned five out of six men who are pledged to oppose a large expenditure upon the gas-works. Bailie Keith, who was one of the chief supporters of the extension movement, was defeated. Only a week ago the Provost was arguing that the community were not sufficiently informed to give a vote in a *plébiscite* upon the question of whether or not the works should be extended. He was probably right. This foreign administrative monstrosity is not well adapted to a case of this kind; and it is altogether unnecessary, because the electors have it in their power to give their opinion at the polling-booth if they wish. The community have expressed their wish in this matter. They want the gas-works to remain where they are; and if it is necessary to expend money upon them, let it be a moderate sum to keep them going—particularly let all improvement schemes be dropped which would involve the expenditure of a large sum of money in the expectation of a small annual saving. The decision may in the end be wrong. The public are easily frightened upon questions connected with large outlays; and this appears to have been the case here. Before any moderately extensive scheme can be carried, the Gas Commissioners will probably find it requisite to give more information, and tie themselves down to something reasonably definite. The vote, at the worst, means delay, and if the time be usefully employed, there need be no reason why the Commissioners should not be able to carry through at the next election the scheme they may resolve upon. They will very shortly have the benefit of Mr. Foulis's advice on the subject; and probably, all things considered, it is just as well that decision upon the question, even by the community, is delayed until after his report has been received.

Mr. Adam Pratt, the author of the gas agitation in Aberdeen, has, contrary to my expectation, been returned to the Town Council. This success is attributed to the adroit use of "means." It looked as if Mr. Pratt must succumb before the reduction of 4d. in the price of gas announced by the Gas Commissioners a week before the election, when, lo! he suddenly turned that circumstance to his own credit; and with its aid went in by a swinging majority. When the electors rose on the morning of the election, they found the walls of the city placarded with posters inviting them to vote for Mr. Pratt who had been "the means of reducing the price of gas by 4d. per 1000 cubic feet." This is understood to have turned the scale in his favour. It is to be hoped that the Council will, in justice to Mr. Pratt, seeing that he has been returned on account of his discontent with the gas management, put him on the Gas Committee; and if nothing has been wrong in that department—which I take to be the case—the wind would then be taken out of his sails, and the victory would lie with the Committee.

The quiet academic city of St. Andrews has just carried through that which was such a bugbear in Edinburgh last year, and in Arbroath this year—a *plébiscite* on gas affairs. A proposal by the Provost to adopt the Burghs Gas Supply (Scotland) Act, 1876, was carried in the Town Council in September by twelve votes to nine. The opposition here was not in respect to the price which the Provost suggested would be sufficient, but that it was certain to be more than the figure he mentioned, and that if the Town Council committed themselves to the adoption of the Act, they would be obliged to go on with the purchase, even although it might come to be compulsory; and they might, at the end of arbitration, require to pay a premium of 100 per cent. on the value of the undertaking. The Provost's figure was £13,250, and was based on the principle of offering £31 5s. for each £25 share. On the other hand, the opposition were convinced that the price would be at least £20,000. There were eleven vacancies in the Council, and each side nominated eleven candidates. Along with the election, arrangements were made for taking the opinion of the electors by means of a *plébiscite*. The result has been a complete victory for the Provost. In the election, ten out of the eleven candidates in favour of acquiring the Gas Company's undertaking were returned; and in the *plébiscite* the numbers were: For, 3861; against, 3013.

The strike at the Leith Gas-Works, to which I referred last week, has unfortunately begun; and there seems as yet no appearance of an ending of it. Indeed it is difficult to see how it can end, except by the Commissioners giving way. If they send men down from Edinburgh, they must pay them the Edinburgh wage; and they may as well pay this to the men on strike as to their substitutes. If they get men to start in Leith at the lower rate of wages which has been current there, these men will either be inferior workmen, or, if they are not, as soon as they have learnt the work, they will be found applying for the rise which has been refused to the men who are out. I confess it is to me amusing to see the Commissioners pleading that this rise was not asked from the Company before the transfer. The workmen most probably did not know what was being earned in Edinburgh; and very likely would not have known except for the Commissioners telling it themselves. But over and above that, the men were the employees of the Leith Company only, whereas they are now co-employees with the Edinburgh men of the Commissioners; and they reason—and I think rightly—that when they do the same work they ought to have the same wage.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

Bailie Mackenzie, a leading member of the Paisley Town Council, in addressing his constituents recently, referred to the affairs of the Gas Trust. He said that there had been a difference of opinion amongst the members this year. Ought they, he asked, to levy (say) £5000 from the gas consumers more than was required to pay their expenses? They already had an improvement rate of 5d. per £1 of rental, which must be paid between landlord and tenant; and the sum he mentioned would come almost to another 5d. in the pound. He was one of the minority who

opposed charging such a high price for the gas in order that a surplus might be obtained. Returns from the important burghs of Scotland showed that Paisley was the most highly taxed town in Scotland, with the exception of Perth; and he thought they should consider carefully how they endeavoured to raise surpluses in connection with any Trust, because such surpluses were simply a tax upon the public. One of Baillie Mackenzie's colleagues—Baillie Andrews—traces much of the prosperity of the town, as a manufacturing community, to the excellence of the gas supply and the cheapness of the commodity. Indeed, he does not hesitate to tell his constituents that the Paisley gas, having an illuminating power of 26 to 27 standard candles, is, at 3s. per 1000 cubic feet, without doubt, the cheapest gas in Scotland. He says that during last year, after deducting all necessary charges, the Gas Trust had a clear surplus of £5413, which they appropriated for improvements; and his opinion is that if they had no surplus they would require either to stop improvements or put a tax on the ratepayers of 4d. or 5d. per £1 on the rental. If it is the cheapest gas in Scotland at 3s. per 1000 cubic feet, what must it be now, seeing that the price has been reduced to 2s. 10d. per 1000 cubic feet? Baillie Andrews seems to rejoice in the extent of the gas surplus, and in the mode of raising and spending it. He says that there are a few who think, or at least say, that to use the gas surplus for local improvements is a tax on the inhabitants; and he asks how in reason or common sense it can be called a tax, if the gas be sold as a marketable commodity, and sold at a lower price than that charged by any other gas company in Scotland. This has long been a vexed question in Paisley, as well as in other towns in Scotland, where the gas supply is in the hands of the municipal authorities; and it seems likely to remain in *questio vexata* for some time to come. But there are other members of the Paisley Town Council who hold that the method of raising and disposing of a surplus from the gas is wrong in principle; but Baillie Gaudie does not seem to be one of them, for he tells his constituents that the gas undertaking is "the goose that lays the golden eggs," and that, if it were not for the yearly surpluses from the gas, most of the town's improvements would not have taken place, as they had obviated the necessity of increased taxation. He also tells them, however, that within a period of four years, the price of gas had been reduced 11d. per 1000 cubic feet, and that the cheap purchase of coals, combined with careful and judicious management, had brought about that happy state of matters. The gas-works were originally purchased for £40,000; and the cost for the extension of the works was £38,000—making the total cost £78,000. The present estimated value is £102,000.

Some interesting statements regarding the Kilmarnock gas undertaking have lately been made to the ratepayers of the town. The works were acquired from the old Gas Company in 1872; the purchase-money being £43,450. At that time some necessary alterations and additions were made which involved an expenditure of £1500—making a total cost of £44,950. The price of gas was then 5s. per 1000 cubic feet. This was in June of that year; and in the following September it was necessary to raise the price of gas to 5s. 10d. per 1000 cubic feet. Since that time there has been paid off in the shape of mortgage bonds the sum of £11,925; and there has also been about £8000 paid upon the profits for the maintenance of the works. Altogether there has been £20,000 of profits used or been received from the gas-works for those two purposes. The mortgage bonds at present existing amount to £33,025.

On Monday of the present week, the shares of the Partick, Hillhead, and Maryhill Gas Company were offered for sale at 80s. per share; being 5s. under the price wanted by sellers on the preceding Saturday. Buyers tendered 75s., which was also 5s. down; but no business was reported. On the following day 77s. 6d. and 75s. per share were accepted by holders. Sellers again asked 80s. per share on Thursday; but they did not fall in with any purchasers, who were willing to go to 77s. 6d. per share.

At Kilmarnock on Thursday, 17 £10 shares of the Kilmarnock Water Company were disposed of by auction. They were 4 per cent. preference shares, participating in dividend up to 10 per cent. The upset price was £16 10s. per share; and they realized £20 3s. per share. Ten £10 shares of the same Company, 4½ per cent. preference, participating up to 6 per cent. dividend, were exposed at £13 each, and were sold for £15 16s. per share. Some interest is being taken in the stock of the Kilmarnock Water Company, as the Town Council may by-and-by make an endeavour to take over the water supply of the town, in the hope that it may prove to be equally successful with the gas supply undertaking. During the past few years some bitterness of feeling has been shown between the Water Company and the Town Council; alleged delinquencies on the part of the former body having been readily taken hold of by the late Provost of the burgh and his immediate supporters in the Town Council.

The Glasgow pig-iron warrant market has again been very quiet this week. There is a prospect of further curtailment in the production, as another blast-furnace has been blown out at the Eglinton Iron-Works. Yesterday afternoon the prices of Scotch warrants were but slightly over 41s. per ton; Cleveland iron was quoted at 33s. 9d.; and hematite iron at 41s. 3d. per ton.

A somewhat demoralized condition is now showing itself in the coal trade, as the miners who have not obtained the advance of 10 per cent. on their rate of wages are likely to make their influence felt amongst the dissentient coal-masters. The shipping department is feeling the influence already, as the men are not working full time, knowing that there is a large demand. Prices are advancing all round.

CHARGE OF EMBEZZLEMENT BY A COLLECTOR OF THE NEW RIVER COMPANY.—Last Wednesday, curiosity was excited in Islington by the statement that one of the collectors of the New River Water Company—Arthur Brookes—had absconded with (as the Solicitor to the Company states) about £400. Brookes was apprehended on Wednesday night, in a public-house in the City, and on the following day was charged with the offence at the Clerkenwell Police Court. He was remanded.

THE THIRLMERE WATER SCHEME.—A special meeting of the Manchester City Council was held on the 31st ult., to consider a Bill which the Corporation intend promoting next session with the object of obtaining further powers in connection with their Thirlmere scheme. The Deputy Town Clerk read a statement to the effect that it was proposed to raise the level of Thirlmere Lake to the extent of 20 feet only at present, which would give 10 million gallons of water per day. This supply was estimated to be sufficient for some years to come. This course would avoid the submerging of a considerable extent of good pasture land at Thirlmere, and render unnecessary for a long period the construction of extensive roads and other works. The proposal had the sanction of the societies for the preservation of the lakes and others interested. The Bill was mainly intended for water-works purposes, and was to be promoted at the cost of the water-works funds. It was not intended to ask for additional borrowing powers. It was also proposed to defer the commencement of the sinking fund for a further period, to be determined by the Local Government Board. Some engineering and other matters in regard to the works are dealt with by the Bill. A resolution in accordance with this statement was adopted.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Nov. 10.

Sulphate of Ammonia.—In spite of the further enhanced values of nitrate of soda, the sulphate market appears to have lost a great deal of its buoyancy. This is somewhat strange, seeing that the present advance in sulphate was mainly due to the improvement in nitrate. Judging by Continental reports, consumers evidently do not believe much in a higher register of sulphate. Hence they abstain from augmenting the quantities already contracted for, although it may be assumed that a moderate decline would tempt them again to operate. The principal business during the week has been done at £12 2s. 6d., f.o.b. Hull and Liverpool; but some business is reported, f.o.b. Leith, at a slightly higher figure. It is stated that December delivery, f.o.b. Hull, can be bought at £12 3s. 9d.; but makers generally prefer to look on, or are quoting higher rates than mentioned. Nitrate on spot is to-day quoted at 10s. 6d.; Spring delivery, 10s. 9d. A cargo Oct.-Nov. sailing is reported to have been done at 10s. 10½d. The higher figures appear to be provoking re-sales. As a matter of fact, second-hand sellers—who are realizing good profits on their cheap contracts—are appearing on the scene, and naturally interfere with business from first hands.

LONDON, Nov. 10.

Tar Products.—The better feeling reported in these products last week is still maintained. Benzols have improved; but it remains to be seen whether the advance is a permanent one. Napthas and tar oil are also strong. Anthracene maintains its value, and a further advance is not improbable. Pitch is better, and more enquired after. Carbolic acid steadily rises, and business has been done at 3s. 9d. per gallon. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. 2d. per gallon; 50 per cent., 2s. 6d. Toluol, 1s. 7d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 1d. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 12s. to 15s. per ton. Carbolic acid (crude), 3s. 9d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 90 per cent., "A" quality, 1s. 6d. per unit; "B," 1s. 3d.

Ammonia Products are scarcely so strong, although £12 2s. 6d. to £12 3s. 9d. is still the value of sulphate. Prices of other products may be taken as follows:—Gas liquor (5° Twaddell), 7s. 6d. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £27. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Nov. 10.]

Sulphate of Ammonia.—There is not as much "go" in the sulphate market as there was this time last week; but prices keep very steady, although it is stated that £12 2s. 6d. is the highest buyers will pay for this month's delivery at Hull. Makers are asking, however, £12 5s. very generally; but buyers cannot be induced to pay this figure. At Leith, £12 5s. is quoted for prompt delivery; and it is reported that £12 10s. has been paid for November to March by a certain speculator. Beckett still keeps firm of £12 5s.; and a similar price is ruling for London outside makes. The nitrate market keeps firm; and dealers are quoting 3d. advance for spring delivery.

Tar Products.—The market remains in much the same state as given in our report last week. If anything, prices are ½d. back for 90's benzol—making the current price for that commodity 3s. 1d., and 2s. 5d. for 50/90's. Solvent naphtha is very firm; and creosote is still in good demand at old rates, while a change seems to have taken place in the position of crude carbolic acid—one firm of users having set themselves to work to buy up as much as it is possible for them to get hold of. For a time this may keep prices moderately high; but the producers must look after themselves. Anthracene remains unchanged. It is quite as strong as ever; and there are some makers who believe in a further hardening of prices. The pitch market is now in a good and healthy condition; and the prices quoted for last week may serve equally for to-day. The stiffness of prices for most of the finished tar products being well maintained has not been without its influence on the tar market; and the tar distillers are beginning to complain bitterly of the high prices they are obliged to pay for this article.

BURSTING OF A RESERVOIR NEAR GENEVA.—Last Tuesday, the water reservoir at Montreux, used for the service of the electric railway, burst. Several houses were swept away by the rush of escaping water; and ten people are reported to have perished by the catastrophe. The villages of Sonzier, Pertit, and Vuarrennes have been devastated.

CHESHUNT WATER SUPPLY.—In consequence of the great dearth of water experienced in the district of the Cheshunt Local Board, this body has decided to proceed immediately with the construction of water-works of their own. Land for the purpose of sinking a well has been purchased at Cuffley; and, as the result of a trial boring, it is anticipated that an abundant supply will be obtained. A scheme has been prepared, which has been approved by the Local Government Board. The estimated cost of the work is £25,000.

GAS EXHIBITION AT RAMSGATE.—On Monday, the 29th ult., an exhibition of gas appliances was opened, under the auspices of the Ramsgate Corporation Gas Department, in St. George's Hall in that town, and continued during the week. In the absence of the Mayor, the opening ceremony was performed by Mr. Alderman Turpin. After a few preliminary remarks, he introduced Miss Cameron, who proceeded to give the first of a series of lectures on high-class and plain cookery, with illustrations. The gas-stove exhibits were mainly supplied by Messrs. T. Fletcher and Co., of Warrington. There was a special stand, fitted up by the Gas Department, showing lamps and burners of different designs, for the guidance and instruction of consumers, as also glass-cased wet and dry meters. A large number of Messrs. W. Sugg and Co.'s lamps, burners, and governors were also on view. The exhibition was under the superintendence of Mr. W. A. Valon, Assoc. M. Inst. C.E., the Gas and Water Engineer of the Corporation.

INCREASED STORAGE AT THE COLNEY HATCH GAS-WORKS.—On Monday afternoon last week, a large and important addition to the works of the Colney Hatch Gas Company was brought into use by the inflation with gas of a new holder, constructed from the designs of Mr. Jabez Church, M. Inst. C.E., the Company's Consulting Engineer. The holder is arranged to be telescoped in a short time and with little trouble when required; the whole of the guide-framing having been completed. The latter is composed of 14 wrought-iron lattice T-shaped standards, with lattice girders and "Paddon" ties, and is a light, strong, and by no means inelegant structure. When completed the holder will be capable of containing 450,000 cubic feet of gas. Messrs. John Aird and Sons constructed the tank, retaining walls, and other works; Messrs. T. Cutler and Sons, of Millwall, being entrusted with the holder. Mr. W. F. Broadberry, the Company's Manager, filled the position of Resident Engineer during the construction of the works.

THE NORTHERN COAL TRADE.—The demand for coal continues large, and the prices firm; but the extreme briskness generated by the Yorkshire coal strike is passing away. The inquiry for steam coal is still brisk, at about 8s. 6d. per ton for best qualities; but the small coal is produced so largely that the market is glutted, and the price is lower. For gas coal there is a pressing demand, and the price is more than maintained. Some of the chief collieries are far behind with deliveries; and therefore the amount of coal for sale at present high prices is very small. Thus the price of 8s. per ton which is spoken of, and which has, it is believed, been paid in one or two instances, is for a very limited quantity. The demand is now nearly at its maximum for gas coal, but it will remain at its present height for probably six weeks; after this a fall may be anticipated. The cost of the freight of coal seems to be tending upwards, however; and thus, though the contracts for coal may have been placed at low prices, it will be a little dearer to some buyers.

END OF THE GAS-SUPPLY DIFFICULTY AT TONG.—Our readers may remember that a contest as to the right of gas supply in the Tong and Dudley Hill neighbourhood of the Drighlington Gas Company's area has been going on for a considerable time between Mr. Matthew Hillas, of Dudley Hill, and that Company. Mr. Hillas, whose mill premises are partly in the Bradford borough and partly in the Drighlington Company's district, has for years obtained gas from the Bradford Corporation, and passed it through his meter in the borough into the district of the Company. This caused a great deal of litigation, which ended last year in Mr. Hillas and his supporters (including the Tong Local Board) defeating the Company before a Committee of the House of Lords. The Drighlington Company then reduced the price of their gas from 3s. 9d. to 2s. 6d. per 1000 cubic feet. Having established the principle that no private person can be prohibited from supplying gas in any district in which a company have, under their Private Acts, a right of supply, Mr. Hillas has now sold his plant to the Gas Company.

THE NEATH CORPORATION AND THE WATER SUPPLY.—At the meeting of the Neath Town Council on Monday last week, Mr. Cuthbertson complained of the quality of the water supply in the town, and moved—"That the Town Clerk be instructed to apply to the Neath Water Company for terms for the purchase of their rights—firstly, for the Neath water undertaking; secondly, for the Briton Ferry undertaking; and, thirdly, for the joint undertakings—and for a return showing the annual income and expenditure." Mr. Markham seconded the motion. Alderman Charles thought there was another way of dealing with the Company; and rather than go in for purchasing their works, he would apply for power to construct works of their own. He moved, as an amendment—"That the Town Clerk be instructed to have Counsel's opinion as to what steps (if any) should be taken to obtain a continuous supply of water, either under sections 35 and 36 of the Water-Works Clauses Act or the Company's Act of 1885, or in the alternative to construct their own works." After some conversation, Mr. Cuthbertson withdrew his motion, and the amendment was unanimously agreed to.

THE PROSPECTS OF THE ELECTRIC LIGHT AT BRISTOL.—In reply to a question put to the Chairman of the Bristol Sanitary Authority (Mr. Naish), at the meeting of that body last week, as to whether the time had not arrived for the adoption of the electric light in Bristol, he said that a Committee had been appointed, and probably during the next twelve months the matter would be advanced. They had already had an offer from a gentleman who had succeeded in placing the electric light at Bath and Taunton. They had given him the cost of gas throughout the main streets which it was suggested should be lighted in Bristol, and it was pointed out to him that the Committee would probably agree to adopt the electric light if it could be supplied at the same cost as the gas. He (Mr. Naish) did not think that at present it could be done at the same cost; but the system had been adopted in other towns, and he thought the time was arriving when it should receive the consideration of the Bristol Corporation. Mr. Lockley (Vice-Chairman of the Committee) pointed out that the question had lately been under consideration at Exeter; and he observed that the Council of that city decided not to accept any of the tenders for electric lighting, on the ground of the increased cost as compared with gas. The subject then dropped.

THE LIABILITY FOR DAMAGE TO PUBLIC LAMPS.—In reference to the application in the Queen's Bench Division by the Chester Gas Company for a special case against the Justices of Chester, in the matter of an information against John Challinor for breaking and damaging a public lamp (see ante, p. 808), *The Times* of Wednesday last contained a report of a case which is almost identical with that at Chester. It came before Mr. Justice Field and Mr. Justice Wills, and raised a question as to whether, when a driver has accidentally injured a street lamp in the Metropolis, his employer is liable for the damage under the provisions of the Metropolis Management Act. The complaint was preferred by Mr. E. C. Harding, Clerk to the parish of St. Mary Abbots, Kensington, against Messrs W. A. and W. Barker, market gardeners, under section 207 of the above-named Act, for having, on June 11, 1887, carelessly or accidentally broken "a certain lantern and the fittings thereof opposite the Town Hall, Kensington High Street," for which they claimed damages to the extent of £8 17s. 6d. On Nov. 1, 1887, the Justices dismissed the complaint. A case was, however, stated and argued before the Queen's Bench Division on April 11, 1888, when it was remitted for the Justices to find whether the act complained of was a careless or an accidental one, and for them to rehear the case for that purpose. The Justices decided that it was an accident, and the Court confirmed their decision; thus absolving the master from liability.

DEFRAUDING A GAS COMPANY.—At the Accrington Police Court last Wednesday, a potato dealer named Solomon Williamson, who carries on business in Grange Street in that town, was charged with fraudulently using the gas of the Accrington Gas and Water Company at his storehouse in St. James's Street. There were three summonses issued against the defendant; and the Company claimed £5. The Town Clerk (Mr. Aitken) represented the Company, and Mr. McKeand, barrister, appeared for the defendant. From the evidence adduced for the prosecution it appears that the defendant occupied the lower portion of the premises in question, one part being used as a stable, and the other as a warehouse. There was formerly a gas-meter in the cellar; but this was disconnected by the Company some time ago and removed, though a short pipe remained. On the 7th and 8th of October, constables saw a large blaze of gas in the warehouse, and defendant was informed of the matter. He replied that it would be all right; but the constables insisted on his accompanying them to the place, and this he did. It was then discovered that he had been using the gas from the short pipe left by the Company—the pipe having been flattened at the end. Mr. Aitken explained that there was evidence that the defendant had been abstracting gas for a considerable time. The Magistrates considered the cases proved, and inflicted fines of 40s. and costs in each instance. The question of damages was then heard; and, after some discussion, Mr. McKeand agreed to pay 40s., which was accepted by the Company.

SUNDAY LABOUR AT THE WEST BROMWICH GAS-WORKS.—At the meeting of the West Bromwich Town Council last Friday, the Gas Committee reported that, having received a memorial from the stokers and coal wheelers requesting that extra remuneration should be granted to them in respect of Sunday labour, they had instructed the Manager to dispense with Sunday labour as far as possible; but when this was found impracticable, the stokers were to receive a bonus of 1s. 6d. per man, and the coal wheelers 1s. per man in addition to their day's wages.

PUBLIC LIGHTING AT THE EAST-END.—At the meeting of the Vestry of Mile End Old Town last Wednesday, the Chairman of the Highways Committee (Mr. Loftus), in answer to a question, stated that the general review of the lighting of the hamlet was under consideration, and the conclusions arrived at would be duly submitted to the Vestry for approval. In the course of an irregular discussion, it was generally urged that there were many dark places and alleys which needed lamps. In the end, it was ordered that three lamps should be set up in places recommended by the Committee.

LIGHTING OF LLANDAFF WITH GAS.—The smallest city in the United Kingdom has followed others in the run of civilization, and at last has its streets lighted with gas. This change took place a few evenings since; and the inhabitants were so rejoiced at the event that they turned out *en masse*, as if the place had been illuminated for some special occasion. Llandaff has hitherto been behind other places—the old oil-lamps remaining there until recently; and the late Bishop frequently carried a lamp to light the way from the Palace to the Cathedral during the winter evenings. The gas is supplied by the Cardiff Gas Company; and the street lamps are the same in every respect as those used at Cardiff.

SINGAPORE GAS COMPANY, LIMITED.—At the half-yearly meeting of this Company to be held to-day will be submitted the Directors' report and the statement of accounts for the six months ending June 30 last. The accounts showed that the gas and meter rental produced £7518 16s.; and products, profit on fittings, and sundries, £2688 18s. 6d. These two sums, together with the balance brought forward (£349), make the receipts for the half year £10,557. The expenditure amounted to £7931 13s.; leaving a balance for appropriation of £2625 7s. Out of this sum the Directors recommend the declaration of a dividend at the rate of 7½ per cent. per annum, less income-tax. During the half year the buildings, plant, machinery, and pipes have been maintained in a good condition; repairs and renewals having been executed where necessary, including the re-instatement of the coal-stores. Two new purifiers and 48 extra public lamps have been erected, new mains laid, and a large amount of excavation for the new gasholder tank has been carried out. The collections, the Directors state, have been very satisfactory.

THE GAS SCANDAL AT HALIFAX.—At a meeting of the ratepayers of Halifax held last Thursday, a resolution was passed thanking the Mayor (Mr. Alderman J. Booth) and the other members of the Special Committee appointed to deal with the charges lately made in connection with the Corporation Gas-Works, and expressing the sympathy of the meeting with them in their efforts to thoroughly investigate the matter. The Mayor, in responding, said that he and his colleagues had resolved that, come what might, whatever time, labour, and trouble it might bring, if it was possible to get at the bottom of the scandal they would root it out. It was high time that the question should be gone into, for he "could a tale unfold" that would, he thought, astonish them—exceedingly astonish them. But, as the matter was being sifted, and had to be wormed out, so to speak, bit by bit, it was better that he should not for the present say more. There would be a time, however, when he could open his mouth, and tell them a great deal that had been going on, and which had not yet been made known to the public.

ELECTRIC LIGHTING AT BARNET.—At the meeting of the Barnet Local Board last Tuesday, the Lighting Committee reported that the electric lighting contractor (Mr. Joel) had been in communication with them on the subject of the complaints made in regard to the lighting, and had stated that he had every reason to believe that everything would be in proper working order by the 20th inst. The Committee had inspected a 32-candle power lamp; and the contractor had undertaken that all the lamps should be worked to a similar standard, with the addition of reflectors and improved appliances. The report having been received, Mr. James said that; taking into account the time which had elapsed since the first attempt to light the town by electricity, he thought the Board should take some decisive action. They had had a good many

promises, but none of them had been carried out. He proposed that notice should be given to the contractor to terminate his contract; expressing the opinion that by so acting the Board could not be accused of undue haste, or want of consideration. Mr. Samuels pleaded for the contractor; saying that he considered the Board would do a very unwise thing if they gave the notice. He moved, as an amendment, that the recommendation of the Lighting Committee as to the notice be not acted upon; and this was adopted.

SOUTHAMPTON GAS COMPANY.—The half-yearly general meeting of this Company was held last Wednesday—Mr. R. C. Hankinson in the chair. The Directors' report stated that the profit and loss account showed that the amount available for division was £7577 1s. 4d. The Directors recommended the payment of maximum dividends amounting to £7004 1s. 10d. for the half year on all classes of shares, less income-tax; leaving a balance of £572 19s. 6d. to be carried forward. The Chairman, in moving the adoption of the report, said that during the six months to which it referred, the Company had sold more gas, there had been a little improvement in the price of residuals, and the price of coals was low. Mr. R. R. Oke having seconded the motion, Mr. J. B. Paddon (the Company's Consulting Engineer) said it was his intention to have brought the new gasholder into operation the last day of October, but unavoidable circumstances had caused delay; though all the difficulties—none serious in themselves—had now been successfully overcome. The report was adopted, and maximum dividends declared. On the motion of the Chairman, seconded by Mr. H. Lashmore, a recommendation from the Directors that the salary of the Secretary (Mr. C. Crowther Smith) be increased by £50 per annum was adopted. Votes of thanks to the Auditors, the Manager (Mr. S. W. Durkin) and staff, Directors, and Chairman closed the proceedings.

THE QUALITY OF THE LONDON GAS SUPPLY
DURING THE FOUR WEEKS ENDED NOV. 6.

EAST LONDON WATER-WORKS COMPANY.

ISSUE OF NEW CAPITAL.

NOTICE is hereby given, that the Directors are prepared to receive TENDERS for £53,000, being the third portion of the New Perpetual Debenture Stock of the Company, to bear interest at 4½ per cent. per annum, free of Income-Tax, such tenders to be delivered at the Company's Offices, St. Helen's Place, in the City of London, not later than Four p.m. on the 3rd day of December, 1888, and payment of accepted tenders made on the 22nd of December.

Particulars and conditions, together with form of tender, may be obtained at the said Offices, or will be forwarded on application.

By order of the Court of Directors,
ISAAC ADOLPHUS CROOKENDEN,
Secretary.

St. Helen's Place, London, E.C., Nov. 1, 1888.

TO INVENTORS AND PATENTEES.

MR. W. H. BENNETT having had considerable experience in matters connected with Gas, Water, and Sanitary Improvement, begs to say that he continues to assist Inventors in the perfection of their designs, and to obtain for them PROVISIONAL PROTECTION, whereby their Invention may be secured for Twelve months; or LETTERS PATENT, which are granted for Fourteen Years.

Patents completed, or proceeded with at any stage, thereby rendering it unnecessary for persons resident in the country to visit London.

Patents procured for Foreign Countries. Information as to cost, &c., supplied gratuitously upon application to the Advertiser, 22, Great George Street WESTMINSTER.

BELGIAN CLAY RETORTS.

J. SUGG and CO., late ALBERT KELLER, GHENT.—The removal of the import duties on Earthenware permitting the entry of Clay Retorts into England, Messrs. Sugg, of Ghent, beg to draw the attention of the Gas Companies of London and other cities to the very superior quality of the RETORTS manufactured by them. They can be made of any size, in one piece, and of any form. The price will be in proportion to the weight, and very moderate in comparison to their value.

Communications addressed to J. Sugg & Co., GHENT, will receive immediate attention.

ROBERT MARSHALL,

CANNEL COAL MERCHANT,

97, WELLINGTON STREET, GLASGOW.

Prices and Analysis of all the Scotch Cannels on application.

THE ONLY RELIABLE

DRY CENTRE-VALVE,

WORKING ONE, TWO, THREE, OR FOUR PURIFIERS ON AT THE TIME.

Also MADE FOR TWO OR THREE PURIFIERS.

No Springing. No Leakage. No Foul Gas passed in Changing. Special Facility for Blowing the Air out of the Fresh Box before putting in Action, without driving it forward into the Holders.

Write for Prospectus.

Also DOUBLE-ACTION DOUBLE-FACED GAS & WATER VALVES.

F. WECK, 86, NEW STREET, BIRMINGHAM.

GEO. WELLER & CO.,

Consulting & Contracting Gas Engineers,
SUFFOLK HOUSE,

LAURENCE POUNTNEY HILL,
CANNON STREET, LONDON.

GAS-WORKS LEASED

On Special Terms or Guaranteed Dividends.

Contractors for the Erection of New and Remodelling of existing Gas-Works from own or Engineers' Drawings.

25 Years' experience in Gas Manufacture and Distribution in London and the Provinces.

ESTIMATES GIVEN.

Agents for Fire-Clay Goods and other Gas-Plant. Also for Foreign Gas Companies.

All Communications to be addressed to the Firm.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, NOVEMBER 20, 1888.

THE REPORT OF THE STANDARDS OFFICE.

THE annual report by the Board of Trade on their proceedings and business under the Weights and Measures Act, 1878, has been presented to Parliament. Mr. H. J. Chaney, the Controller of the Standards Department, generally contrives to make his annual statements worth looking into; and this year's is no exception to the rule. The report as a whole gives one the impression that this particular Government department is very well occupied. It shows that the Standards Office is employed in the verification of weights and measures not only for the United Kingdom and its colonies and dependencies, but also for the world at large; for in regard to gas-measuring apparatus, we learn, from the first page of the report, that such apparatus has been verified during the year for "the city of Stockholm and the town of Kalmar, in Sweden," in addition to other places with more obvious claims upon the British standards officials. It is advisable to remark, before entering into the examination of the details of this report, that a measure is now before Parliament, and

was to be read a second time last night, for amending the law relating to weights and measures in sundry respects that have been recognized as desirable in previous reports. One of the divisions of this Bill relates to the sale of coal. It provides that all coal shall be sold by weight only, under a penalty of £5 for transgressions of the law. Coal retailed in sacks must be in weights of 2 cwt. downward, in aliquot parts of the hundredweight. Regulations are also included for the retailing of coal in bulk, and defining the powers and duties of local authorities in respect of dealings in coal. The Bill contains clauses relating to the weighing or measurement of various commodities; among others providing that the Board of Trade shall from time to time cause to be made and verified any required new denominations of standards for the measurement of electricity, temperature, pressure, or gravities. It is a purely administrative Bill; and it is to be hoped it will become law in the current session of Parliament.

To return to the substance of the report, we notice a paragraph which states that the suggestions drawn up by the Department with reference to the sizes of screw-threads and connecting-pipes to be adopted for gas-meters have met generally with the approval of those practically interested; and a list of the several standard sizes finally agreed upon is attached. It may be remembered that the opinion of the Council of The Gas Institute, as representing the gas industry of the country, was asked upon this matter; and a reply delivered to the effect that the standardizing of gas-meter unions would be desirable. Accordingly a page of the appendix to the report is devoted to illustrations and descriptions of the steel gauges made for meter connections, and to figures explanatory of the form and construction of the union-fittings. It may be trusted that the step thus taken by the Standards Office will prevent for the future a good deal of the trouble that has been experienced in the past in making good meter connections. The Department has also paid attention to the testing of weighbridges, especially such as are employed for weighing coals in trucks. In Lancashire alone over 300 weighing-machines at collieries have been examined during the past year; but it is recognized that the thorough examination of such machines is not often practicable. The report goes on to state that representations have been made as to the want generally of a better system of testing and inspecting all weighing-machines used in trade. In many districts the local authorities do not possess the requisite means of testing weighbridges; and consequently the law relating to the testing of such machines must remain a dead letter. It is declared—and the statement is a very grave one to appear in such a document—that "fraud and trickery in the use of weighing instruments appears to be increasing; and it rests with local authorities, by a systematic inspection, to see that sellers who do not resort to fraud or trickery have that protection which it is the intention of the law to afford them against the unfair competition of those who sell by false weight." Respecting the due testing of weighbridges, it is pointed out in the course of the observations of the Superintendent that it is desirable to do this with verified standard weights only; but it is not easy to get in all districts the ton of such weights declared to be desirable for making the test. Iron is not a very suitable material for standard weights; but it is cheap. Gun metal would be better; but local authorities will not go to the expense, and therefore inspectors are obliged to do the best they can with iron, although it is admitted to be liable to damage under the rough handling to which it is exposed, as well as to rust. It is remarked that a weighbridge ought to turn with a weight of about 4 lbs.; but no hard-and-fast rule is laid down on the point.

The observations of the Superintendent upon matters that have been referred to the Standards Office during the year are sometimes very interesting. Among these remarks we read that a question as to the legality of the measure of a "chaldron" having arisen, it has been pointed out that the Act permitted the use of such a denomination. The chaldron is defined as containing 36 imperial bushels, not heaped, but filled in all parts as nearly to the level of the brim as the size and shape of the article measured will permit. Our readers do not need reminding how awkwardly the legally-enforced obligation to "strike" the imperial bushel measure applies to such a lumpy commodity as coke. It is observed that there is nothing in the Act to require dry measures of capacity to be of any particular shape.

A variety of interesting matter of a scientific order is to be found in the appendices to the report. Thus the comparison of length between the metre and yard is made the subject of

a special note. It appears to be almost practically impossible to duplicate standards, or to obtain an exact comparison between the metre and yard measures; the latter question being further complicated by the consideration that, whereas the standard yard measures a true yard only at the temperature of 62° Fahr., the standard metre only measures a metre at 32° Fahr. It follows from the tests of the Standards Office that the only means of ascertaining the exact comparative lengths of the English and French standards of lineal measure would be by examination of the two standards side by side; and as the English standard cannot be exported, nor is it likely that the French one can be borrowed for this purpose, the matter rests with an approximate determination. There is one thing that we miss from the report; and that is the question of photometrical standards. Is anything to be done at any time to replace the discredited candle with a more reliable standard? There have been enough reports upon the subject; but there is no sign of any positive action in the matter such as the Board of Trade could very easily institute. The Board have promoted the Weights and Measures Amendment Act already referred to in this article; but although taking power to formulate standards for the measurement of "electricity, temperature, pressure, or gravities," as the phraseology of the Bill states it, there is not a word about standards of illuminating power. It may be as stated on many occasions that special action is required to dethrone the sperm candle legalized by so many Acts of Parliament, and to set up anything else in its place; but the subject might at least have found passing mention in the report, considering how the Metropolitan Board of Works have assisted the Board of Trade by inquiring into the merits of the candle and its possible substitutes. We understand that the authorities responsible for the examination of the gas supplied to the Metropolis have arranged for the regular trial of different proposed standards by the gas-testing officers at several photometrical stations. This is a point which the Board of Trade should take note of, with a view to glean information respecting the behaviour in ordinary usage of such standards as may be substituted for the candle. It is possible that the Department may prefer to observe how pentane works for a year in two or three testing stations before taking steps to legalize its use upon recommendations based on special investigations. What we are complaining of, however, is the complete silence of the report regarding this question, which is certainly one of the most important and pressing of the affairs that may be assumed to be now under the notice of the officials of the Standards Office. The Department cannot require further inquiry into the matter; but it is possible, as we have recognized, that some experience may be sought before action is taken. Another year cannot pass, however, without this business being settled in one way or another. Either candles must be retained *faute de mieux*, notwithstanding their shortcomings, or pentane will come to the fore. The existing state of uncertainty cannot be indefinitely protracted. Has Mr. Chaney taken notice of what Mr. Dibdin said at the last Gas Institute meeting respecting the condition of gas testing in London? His declarations on this occasion constituted a grave impeachment of the system under which the shortcomings which he then mentioned have become possible. And this trouble can be so easily remedied, if the Board of Trade once satisfy themselves that the time for legislative action has arrived. A short departmental Bill could be passed through Parliament without any appreciable difficulty; and the existing unsatisfactory condition of things, which amounts to a scandal and a reproach to modern science, would be at an end. If such action is not to be taken, one would like to know some better reason for letting things alone than is at present apparent.

PROPOSED LEGISLATION RESPECTING "COMMISSIONS."

The report of the Royal Commission on the proceedings of the Metropolitan Board of Works, to which we have already referred in a previous issue, terminates with an important recommendation on the subject of "commissions." It is suggested that, in view of the facts elicited by the inquiry, it might have a wholesome effect if it were distinctly made a criminal offence to offer to any member or official of a public body any kind of payment, fee, or reward having any relation to the affairs of the body in question; and also to make the acceptors of such payments amenable to the criminal law. The Commissioners do not propose any definite plan for legislation upon this subject, but suggest that the provisions of the Corrupt Practices Act might be taken as a model. This recommendation of the Commissioners is not to be

allowed to pass unnoticed, for Lord Randolph Churchill has already notified his intention of stirring up the Government to take action in the matter. It is to be hoped that something will be done to deal with the evil of which such glaring examples came under the notice of this Commission; but we fail to see why remedial measures should be confined in their application to members or officials of public bodies. The mischief pervades all departments of trade and manufacture, as well as official life; and to attempt to keep it out of the latter, while allowing it to rage unchecked through the remainder of the business community, would be as idle as to think to keep the cattle plague out of one particular field of an estate while its victims surrounded it on every side. The evil must be legislated for as a whole; or not at all. There is no particular difficulty in the way. It has only to be enacted that any person occupying a position of trust, in which he has power or influence over the outlay of money belonging to other people, or in any way acts on behalf of others, who receives payments of money or private benefits of any kind in relation to the affairs of his employers or those whom he represents, shall be guilty of a criminal offence. The same would, of course, apply to anybody who offers or pays any such private or secret considerations intended to influence business. Surely, some member of Parliament, if not the Government, could undertake a work so badly needed as this. The "commission" system has many ramifications and disguises, but it all comes back to the central idea of a private payment to an agent in connection with the affairs of his principal; and the law that effectually grapples with the evil must apply to all occupiers of a wholly or partially fiduciary office, from members of Parliament and of local governing bodies down to shopmen. There is no branch of industry or department of official life in which an honest man is not liable to be injured by the venality of his fellows. It is in the interest of honest agents not less than in that of principals, that stringent and effectual legislation is urgently called for. So long as it is possible for the "pickings" or perquisites of an office to be recognized as natural accessories to the salary attached to it, so long will a deaf ear be turned to the complaints of poor pay emanating from salaried officers popularly supposed to be favourably situated for gathering such "unconsidered trifles." How often is the remark heard in all classes, and with regard to appointments of every degree: "The salary is rather small, it is true; but that is not all." If salaries attached to official positions are to be improved, it will be only by virtue of the prevalence of a clear understanding that the holder has nothing more to rely upon. It should scarcely be necessary to insist upon the importance of bringing the payers of "commissions" under the same ban as the receivers. The Corrupt Practices Act, to which allusion has been made, would have vainly attempted to check corruption on the part of voters if it had not fixed the heaviest responsibility upon the candidates. Similarly, if the acceptance of illicit "commissions" should make the receiver liable, under a new Act, to a maximum term of imprisonment without the option of a fine, the maximum punishment allotted to the payers of the commission should be at least double. This would make the whole tribe of bribing traders pause in their wicked courses, and would result in the end in materially altering the course of business, because quality of goods and honest prices would for the first time have fair play.

REMARKABLE RESULT OF A LEAK OF GAS.

A CURIOUS case, arising out of a leak of gas from a main, has just been heard by Mr. Justice Denman and a special jury, and will be found reported elsewhere. The plaintiff was a solicitor residing at Carshalton, and the defendants were the local Gas Company. It appeared from the evidence that in October, 1885, the plaintiff discovered a leakage of gas into his wine-cellar, and also in certain parts of his grounds. He thereupon alleged that damage amounting to £70 or £80 was done to his wine by the escaped gas, and that he was put to serious expense in other ways in consequence of the undesirable entrance of gas upon his premises. It is impossible to form any but a particular opinion of such claims as these; and the Company's case—that while admitting the fact of the escape of their gas in the manner stated, the amount of damage done thereby was grossly exaggerated—reads like obvious common sense in comparison. At all events, this was the view of the jury, who decided that there had been no negligence on the part of the Company, and that £5 would cover all the damage. Upon this finding

application was made for judgment to be entered for the defendants with costs; and this was done. The gentleman who was so unfortunate as to keep a cellar full of wine that could be destroyed by an accidental leak of gas, is probably sorry that he did not act differently when he found himself in collision with the Gas Company. It is letting him off very easily to say merely that his claim was "grossly exaggerated;" but remembering how severely he must have been punished in pocket by the failure of his suit, it is impossible to say hard things of him by way of comment. If he made a mistake, he has been forced to suffer for it.

Water and Sanitary Affairs.

THE time-honoured custom of "straining at gnats" and "swallowing camels" is so dear to the official mind, that it would be rash to expect that prompt action will be taken to check the increased pollution of the Thames. Of the gigantic nuisance at Staines, which has now received judicial sanction, and of the wholesale poisoning process proposed to be inaugurated at Weybridge and Shepperton, the JOURNAL has already had something to say. But, in regard to a matter of such vast and vital importance, we shall deem it our duty to say a good deal more. It will be interesting to see how far we shall have the co-operation of our daily contemporaries in drawing public and official attention to the present condition of things, and to the still more appalling prospects of river pollution in the not far-distant future. The daily press is ever ready to give prominence to the supposed delinquencies of the Water Companies. When any trumpety dispute arises between one of the Companies and a consumer, the most is always made of the occasion; and straightway the Companies are pilloried, in the character of greedy and exacting monopolists. Now, therefore, is the time for our contemporaries to show a just and consistent public spirit; and for aiding the Metropolitan Water Companies to secure for their millions of consumers a supply of water, which ought not to be, and need not be, contaminated. The present situation may be described as a tussle between the general public and those whose duty it is to preserve public health, on the one hand, and the rulers of a few ill-managed townships on the other. Hitherto, owing to obstinate adherence to masterly inactivity, and a selfish disregard of the interests of the Metropolitan community, the victory has remained with the minority. Indeed the champions of this great prescriptive nuisance have been strengthened in their position by the recent judgment of Justices Field and Wills. Because their great-grandfathers knew nothing, and cared less, about the principles of sanitation, and loved the old-fashioned method of disposing of sewage by sending it into the nearest stream, those who came after them discover that they can with impunity go and do likewise. Surely this position of affairs, and its inevitable consequences, need only to be thoroughly realized in order that a remedy may be found for a scandal and a danger likely to become intolerable.

It is quite clear that the existing machinery of the law is not capable of coping with the enormous evil complained of. This fact is sufficiently demonstrated by the story of the Staines case. Since September, 1879, the battle between the Local Board of Staines and the Thames Conservators has been persistently maintained. Summary prosecutions have produced no effect; and now even the tedious and costly proceeding by way of indictment has come to nothing. What is to be the next step? To attempt to set the Chancery Division of the High Court to work against the Staines Local Authority would probably involve a large waste of public money and valuable time. Only one remedy will, in our judgment, meet the exigencies of the case—a remedy by Act of Parliament. The interests of Londoners at large must be protected, even if the privileges of a few individuals have to be extinguished. Public policy, apart from pure morality, is against the wholesale poisoning of one's neighbours; and it is to be hoped that the Government will realize and act upon this view before the mischievous effects of river pollution reach a still more sinister stage of development.

To go to the root of the matter, it will be necessary to amend the provisions of the Thames Conservancy Acts. They have been "weighed in the balance" again and again and found wanting; and the present year ought not to be allowed to close without the necessary amendment being provided. A very short Act should be enough for immediate purposes; and there are few, if any, Bills now under the consideration of Parliament which have a stronger claim on the attention of the Legislature, than would be possessed by a practical measure aiming at the preservation of the health of the

Metropolis. We go so far even as to say that if no other method of abating the nuisance can be found, it should be enacted that any person who, after reasonable notice, causes or wilfully permits sewage from his premises to flow into the river should be liable to imprisonment without the option of a fine. Exceptional diseases always demand exceptional methods of cure; and though it might be complained that the suggested form of punishment would be too drastic in its character, we should not fear that many persons would find themselves in durance vile by reason of the passing of such an Act. When it became manifest that they had reached the end of their tether, they would find it both practicable and convenient to mend their ways. In the meantime any larger measure required for the purpose of conferring adequate powers on Local Boards might be carefully considered and intelligently framed. The penal clauses of the Thames Conservancy Acts stand condemned by practical experience of their working. The Acts of 1857, 1864, and 1866, which are to be read as one enactment, enable penalties to be recovered summarily. These penalties may be levied by distress; and, in default of distress, there may be imprisonment. But imprisonment has never been inflicted. Penalties are imposed and paid, and the nuisance has abated not one jot. The theory of the Conservators has been that they had nothing to do with individuals who contributed to the pollution of the river. The Staines Local Board, on the other hand, disclaimed—and successfully disclaimed—responsibility for what those individuals had done, and were continuing to do. There the matter stands; but there it must not be allowed to rest. While legal luminaries are splitting straws, a great wrong is being done to the inhabitants of London; and, if that wrong can only be rectified by abolishing the prescriptive rights of a few property owners to jeopardize the health of the population, the remedy must, nevertheless, be applied, and, assuredly, the sooner the better.

THE Metropolitan Gas Referees have certified that the new testing station in the district of the South Metropolitan Gas Company—at No. 211, Burrage Road, Woolwich—has been fitted up by the Company with proper apparatus, and is now ready for use.

MR. W. CROOKES has presented to the Department of Science and Art a collection of 68 radiometers and similar instruments, for permanent exhibition in the science galleries of the South Kensington Museum. They illustrate the steps by which he was led to the construction of the radiometer, and to the production of motion and of phosphorescence by streams of electrified molecules in high vacua. Many of the instruments are of the greatest historical interest. Among them is included the first radiometer, with many others, which are described in Mr. Crookes's papers in the "Philosophical Transactions of the Royal Society." Nearly all the instruments are in working order.

AMONG the financial schemes of the past week was one launched by Messrs. Baring Bros. and Co., under the title of the Buenos Ayres Water Supply and Drainage Company, Limited, with a capital of £3,500,000, in £10 shares. Later on it is proposed to issue 4 per cent. debentures to the amount of £5,000,000. Our readers will remember that an intimation of the appearance of this project was given in the JOURNAL last week. The Company is formed to take over the concession obtained by Messrs. Samuel B. Hale and Co. from the Argentine Government, for the acquisition and completion of works for the water supply and drainage of Buenos Ayres. The works are to be completed within three years; and under the terms of the concession, the Government are to be paid the sum of £4,200,000, being the amount stated to have been expended during the last 15 years, exclusive of interest. It is estimated that 50,000 houses in the city will be connected with the Company's service, and that the rates therefrom will produce about £720,000 per annum.

ON the occasion of the visit of the Prince of Wales to Derby last week, as the guest of Lord and Lady Hindlip, at Doveridge Hall, and to attend the Derby races, an elegant luncheon-room at the grand stand, which was prepared for his use under the superintendence of Mr. Henry Boden, deserves a passing notice in our columns, as an example of the excellent effect which may be obtained by the judicious use of the "Foo-chow" enamel manufactured by Messrs. Donald Macpherson and Co., of Knott Mill, Manchester. The room was a most successful representation of an old baronial dining-room, with furniture and appointments in keeping; the walls being covered with deal wainscoting made to represent old oak by the aid of the above-named material. Above was a frieze of canvas enamelled with "Foo-chow" dead gold, in imitation of "cloth of gold." Also by means of the enamel, two large round luncheon tables were converted into "old oak;" while an ordinary conventional ceiling was clothed with ribs and bosses which, to all appearance, might have belonged to an Elizabethan or Early Tudor dwelling. The fireplace was of Coalbrookdale iron; but, by the aid of "Foo-chow," it was made to look like majolica. The whole of the decorative work was carried out by Mr. Macpherson and Mr. Boden conjointly, and reflected great credit on their taste and ingenuity.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET. (FOR STOCK AND SHARE LIST, see p. 905.)

A short week and a flat one was that which, for the Stock Exchange, closed on Friday—the house being shut for repairs on Saturday. Every market and almost every stock (except those in which special gambling is going on) has been flat; and “Goschiens” closed on Friday at the lowest figure, we believe, they have touched—viz., 96½. The Money Market is in a somewhat anomalous condition; and things generally are out of joint. The Gas Market, on the whole, has been much calmer; and business has been less extensive. An agreeable feature is the recovery of Gaslight “A,” which very steadily and progressively advanced day by day from 246 on Monday until the final mark on Friday was 252. The nominal quotation shows a rise of only 2½; but actual transactions were more than once recorded at figures above the top price. South Metropolitan are down; but they were standing relatively higher (as we remarked last week) than the other Metropolitan Companies, and would bear a little reduction. The “A” was done on Friday at 299; and it is many a day since it changed hands below 300. The “B” fell 2, but recovered 1 on Friday; the final price being the best of the week—as in the case of Gaslight “A.” The quotation of Commercial has not moved; but transactions have been marked at rather lower figures. We believe this was caused by a quantity of stock being thrown on the market to close an executorship account. The cause being removed, an improvement in price may be looked for. The Commercial Company are just now inviting tenders for £8766 debenture stock, the unappropriated balance of their last issue, at not less than £123 per £100 stock. This seems a moderate price to buy such a high-class security at, free of commission and stamp duty; and the stock ought to realize mere. Suburban Companies offer nothing for remark. Of the Foreign undertakings, Bahia has gone up ½, upon a better state of things being apparent in the accounts; but San Paulo is ½ weaker. Bombay, Buenos Ayres, and Imperial Continental are quoted *ex div.*, at about equivalent figures. Business in Water has been quieter; but all stocks show out very firm. All variations in quotation are upward; comprising an advance of 3 in each of the Southwark issues, and 2 in West Middlesex and Lambeth 7½ per cents.

The daily operations were: On Monday, Gas was moderately active; but prices were very fair, except for South Metropolitan—the “A” falling 2½, and the “B” 2. Water was quite neglected; but West Middlesex and Lambeth 7½ per cent. rose 2 each. Gas was quieter on Tuesday, with greater firmness in Gaslight “A,” which improved 1½. Very little done in Water, at previous figures. Wednesday was rather more active for gas; and Gaslight “A” rose 1 more, but South Metropolitan “A” fell 3. In Water, Southwark ordinary rose 1. Thursday was the busiest day of the week; and Gaslight “A” was still on the upward march; but the “C,” “D,” and “E” fell 1. Water was quiet and unchanged. Activity in Gas continued on Friday, with a marked tendency to improve. South Metropolitan “B” recovered 1; and Bahia rose ½. In Water, Southwark ordinary rose 2 more, and 7½ per cents., 3.

ELECTRIC LIGHTING MEMORANDA.

THE GROSVENOR GALLERY ELECTRIC LIGHTING STATION—A MISLEADING STATEMENT—ELECTRIC LIGHTING IN AUSTRALIA—THE FORTUNES OF THE FAURE COMPANY.

For the first time since its establishment, the Grosvenor Gallery electric lighting station has been shown to representatives of the press; and last week's *Industries* contains a full account of this remarkable installation. Through good and evil report, the managers of this undertaking have persevered in their attempt to make the Gaulard and Gibbs system a working success, until they have not only secured the largest and probably most profitable electric lighting business in England, but have also ascertained by experience the necessary data on which to plan the Deptford station recently mentioned in this column. When that establishment is in working order, the Grosvenor Gallery station will probably be superseded. It will then have served its purpose, and the removal of the generating factory from Bond Street will be a welcome change for all concerned. We cannot withhold an expression of respect for the quiet, determined, and businesslike way in which, on the whole, this Grosvenor Gallery experiment has been carried out. While other electricians have been lecturing all over the country, and telling what wonders they could do if only the “infamous” Electric Lighting Act of 1882 would permit them, the Grosvenor Gallery managers were pushing trade and gaining experience as though no such enactment had been in existence; thus justifying the position always taken up by the *JOURNAL*, that there was nothing in the Act to deter honest enterprise, whatever obstacles it might put in the way of merely speculative ventures. Now that the Act has been amended it is the Grosvenor Gallery people who are ready to take advantage of it first; though we are not by any means sure that they would not have started larger works even if there had not been any alteration of the law, since their business required better accommodation. The practical success of the station has apparently been largely due to the care and skill of the electrician-engineer in charge, Mr. S. Z. de Ferranti, who succeeded to the post in the beginning of 1886, when the station supplied only 1000 lamps in all. At that time the original Gaulard and Gibbs system was

in use; but Mr. Ferranti soon modified this order of things, and introduced a transformer of his own. At present the collective energy of the steam-engines working at this station is 1600-horse power. About 280 customers are supplied, taking 1400-horse power of electrical energy. At the moderate estimate of 10 lamps per horse power, this would mean 14,000 lamps in all—a very different estimate from the 60,000 lights which the station has been reported in some quarters to be supplying. It is not to be wondered at that the Grosvenor Gallery experiment—being well managed, and giving a fairly good light—should have prospered to this extent in such a choice neighbourhood as Bond Street. The lowest charge to any consumer, however small, is £20 per annum, which, as the writer in *Industries* is forced to admit, “is likely to act as a deterrent to very small consumers.” The present charge for current, above the minimum stated, is after the rate of 7½d. per Board of Trade unit, which is not far from gas at 7s. 6d. per 1000 cubic feet. The average consumption per head of the list of consumers is 5-horse power, or (say) 50 lamps, which is admittedly high, and points to the fact that the majority of the subscribers are large consumers—theatres, restaurants, &c. That is to say, as we have always recognized, the only demand is for the purposes of luxury, and would not be paralleled anywhere save in wealthy quarters of the town.

Messrs. Carey and Fricker, electrical engineers and contractors, of Westminster, have issued a pamphlet dealing with the cost of electric lighting in installations varying in size from 50 to 1000 16-candle power lamps, and comparing the cost with gas at 3s. per 1000 cubic feet. Of course, the electricians make out electric lighting to be always cheaper than gas. In a plan for supplying 250 lamps, for example, they show that the electric light would cost £260 a year, as against £328 for gas. This is a little too audacious, even for partisans of electricity; and accordingly Messrs. Carey and Fricker have been gently admonished by some of our contemporaries that they have overshot the mark in their zeal. The time has gone by, however, when much damage could be done in this way. Everybody knows now that incandescent electric lighting is about twice or three times the cost of gas in the United Kingdom; and the assertions of interested parties, however artfully put forward, will not prevail against common knowledge.

The proprietors of the Australian Electric Light, Power, and Storeage Company have just held their sixth annual general meeting—a good old age for a concessionary Brush concern. Of course, there was a loss on the year's revenue account; and equally of course, the Chairman congratulated his auditory upon the splendid future opening up before the concern. The Company was on the point of winding up a year ago, but was kept afloat principally with a view to seeing whether any profit could be made in connection with the lighting of the Melbourne Exhibition. The local agent of the Company succeeded in getting the contract for the lighting of the whole of the buildings; and although it was admitted that there was very little money at the back of the concern, the Directors contrived to get the necessary plant from the parent Brush Company, paying for it as the remittances came from Australia. It may therefore be said that the Brush Company did the work and the Australian Company acted as intermediaries—clearing £4000 or £5000 by the transaction; which means that the Exhibition Commissioners were somehow induced to pay for their lighting so much more than it was worth. These matters are always mysteries, however. The statement of the Chairman was regarded as so satisfactory that he was actually re-elected; and the meeting dispersed without any proposition for winding up being made from either side of the table—a remarkable thing in connection with a meeting of this class of company.

The unsatisfactory state of the law relating to joint-stock companies was illustrated once more last week in the judgment of Mr. Justice Kay in the action brought by the liquidators of the notorious Faure Accumulator Company against certain of the Directors of the now defunct concern. The object of the suit was to make these Directors personally liable for the money that was lost, squandered, and generally misapplied during their tenure of power. It would be impossible, in the limited space at our disposal, to explain all the grounds upon which the Directors were attacked. Suffice it to say that the attempt to make them liable, as though they had occupied the position of trustees, failed signally. It was laid down that directors of a joint-stock company are in no sense trustees; and that they are not personally responsible for any loss that accrues through their mismanagement, provided there is no fraud. A shareholder of the hapless Company has written to a financial contemporary stating that, before going into liquidation, all the Directors and “those in the swim” exchanged their shares with liability for fully-paid shares (how created, nobody knows); leaving about 26 shareholders on the list of contributories liable for calls. This is a strange tale, if true.

NATURAL GAS A FAILURE IN MANUFACTURING OPERATIONS.—Writing to *Industries* on the 3rd inst., the New York Correspondent of our contemporary says: “I hear that the manufacturers of the Ohio Valley are abandoning the use of natural gas and returning to coal, on account of the irregularity in the supply and the high price. Many of them have gone to great expense in changing their plants from coal to gas burners; but the present high price of gas almost prohibits its economical use. Gas should be furnished at as low a price as coal, or lower; but during the past year the expense has been 20 per cent. over what it formerly was with coal.”

GAS MATTERS AT THE MUNICIPAL ELECTIONS.

Gas matters, as usual, received a large share of attention in the municipal elections throughout the manufacturing towns of Lancashire and Yorkshire. In a few instances, the interest has been so great as to well nigh overshadow every other question. At Halifax, Leeds, and Salford gas has had an unenviable prominence; and various phases of so-called scandals have furnished material for many speeches, and texts for numerous election addresses. Some of these speeches and addresses have already been noticed in the JOURNAL; and our readers are sufficiently acquainted with the subjects to which they pertained. It would be as tiresome as it is unnecessary to go over the old ground; and we propose merely to glance at cases in which gas has entered less prominently as a factor in determining the elections.

At Wigan there was a reminiscence of an old scandal in the candidature of Mr. Worthington, who has been Chairman of the Investigation Committee. He seems to have thought it necessary to defend the proceedings of that body; and though he did not throw much new light on what is now to a large extent ancient history, he stated one or two things not generally known. It sounds like an echo of the far past to be reminded that for many months Mr. Worthington hotly denounced the administration of the gas undertaking, and was unheeded until what he calls "the Salford burst-up" happened. The Committee of inquiry which he wanted came then as a matter of course. He was forced to occupy the position of Chairman; and, as he told the electors, found that a great amount of labour had been put upon him. One statement which he made seems to call for some explanation. The first part of his Committee's report has, he said, already been made public property. As, however, no copy of it has been suffered to leave the Town Clerk's office, except upon the personal application of a burgess, the phrase "public property" is, of course, to be interpreted in a modified sense. Under these circumstances, Mr. Worthington's summary of the report is interesting. "While," he said, "no extensive money frauds are made known, it does show that, upon several transactions, a larger price was paid for canal than the colliery people stated they had received. The report also showed that the work in connection with extensions had been varied in almost every particular." "Mind you," he added, "I am not saying that the contractors made these variations of their own accord. There is no doubt they had some understanding, written or verbal; but it was curious that, when the alterations were in their favour—and they were not a few—not a word was said about it." The differences found to exist in favour of the contractors have amounted, it appears, to thousands of pounds, and claims to the extent of £2000 have already been withdrawn. In one case the Corporation have been served with a writ for over £1000; and there are other claims pending. But Mr. Worthington was sanguine that nearly £2000 more will be saved to the ratepayers. It will not encourage municipal reformers to learn that Mr. Worthington lost his election, though his labours in connection with the Investigation Committee were not the only service he rendered the ratepayers. In one of his speeches, he took occasion to warn them against expecting over-much profit from the gas-works. The average net price of gas in Wigan is 2s. 8½d. per 1000 cubic feet, and the charges for interest amount to 1s.; so that, as Mr. Worthington put it, the margin is not sufficient to justify the ratepayers in being sanguine of much relief in that direction. In fact, as another speaker said, though gas is manufactured cheaply in Wigan, the capital stands at a large figure; and the consumption will have to be very much increased before the works will pay. Perhaps the suggestion that advantage would accrue all round from selling gas to the out-townships at a lower rate than is now charged may some day bear fruit.

Rochdale narrowly escaped inclusion in the list of towns in which discussions on the coal contracts have led to charges of maladministration. Several references have already been made to the subject in our columns; and it is sufficient to say here that one member of the Gas Committee charged his colleagues with having practically ignored all the considerations which are supposed to enter into the letting of large contracts, and that the Chairman and other members of the Committee gave a specific denial to each of his allegations. In the end, the author of the original statement publicly declared that he did not impute either wilful neglect or dishonesty to his colleagues. The matter, which at first had a serious look, resulted in a trivial dispute as to which of two qualities of coal is really the cheaper, and as to who knows most of the gas-making properties of coal—the Chairman of the Gas Committee, or a gentleman who started the discussion, and who seems to be connected with the coal trade. This, however, was not the only question affecting the gas-works talked about at the municipal elections. There was a demand from more than one quarter for a reduction in the price of gas. The Corporation sells gas at a high rate, in order to make up for the loss annually sustained on account of the water-works; and though a reduction in the price has been made within the last twelve months, it has only served to whet the appetite of the consumers for more. The question appears to have been very largely discussed from individual points of view. Men who have large gas bills are naturally anxious that the price shall be reduced, even though the rates should, as a consequence, be increased; while, on the other hand, property-owners and others who are large ratepayers, but small consumers of gas, have manifested a strong desire to see the gas and water undertakings "balance each other." It is interesting to note that, in support of the "balancing" theory, the example of Oldham was cited by a speaker, who is evidently unacquainted with

the later municipal history of that town. One of his arguments was that it would be unwise to reduce the price of gas, because it might lead to an abolition of the differential rate charged in the out-townships, and thus extinguish a large portion of the profit by which the loss on the water-works is met. Had he known that, in the case of Oldham, Parliament put a peremptory stop to this system of "plundering" the gas consumer in order that the water consumer and ratepayer may reap the benefit, he might have cast about for some other example to enforce his argument. Another gentleman told the ratepayers that he had long thought over the question of the price of gas, and the propriety of reducing it to the actual cost. The conclusion he had arrived at was that the ratepayers ought to be regarded in two lights—first, as proprietors of the gas-works, and then as consumers. In the former character they are entitled to a fair return on the business done, and in the latter they have a right to purchase the commodity—gas—at a fair price. And there, just as he was becoming interesting, the speaker stopped. In connection with the question of price, it may be worth while to quote the statement that in 1859 the amount of profit was £2902; in 1865, it was £2368; and in the year ended March last, it was £15,502. The latter is a large figure. According to the gentleman responsible for the statistics, it is equal to a rate of 1s. 2d. in the pound; so that if gas were sold at cost price, the addition to the rates to make up the deficiency would be a very substantial one. One other subject referred to in the election speeches was the increase in the salary of the Gas Manager (Mr. T. Banbury Ball). The gentlemen who cut down that advance to one-half of the original proposal of the Gas Committee, made the most of their heroic conduct; and, of course, posed as great economists. It is really wonderful how far a little of the virtue of economy goes in municipal elections.

Since Oldham has been referred to, it will not be out of place to just glance at what was said there, though happily gas was not this year one of the prominent questions in the elections in that borough. Several of the speakers took credit to themselves for the reduction of 2d. per 1000 cubic feet which has been made in the price of gas; but one gentleman rather dimmed the glory of the others by an untimely reminder that the price was reduced because the Gas Committee are not now allowed to make such large profits as before. One Councilman, who was evidently anxious to magnify the importance of the Gas Department, informed the burgesses whom he addressed that, since 1853 the Committee have paid in relief of the rates more than £200,000, and have aided the water-works, when that undertaking was worked at a loss, to the extent of £100,000.

The ratepayers of Bury continue to be vexed by what they consider the excessive sinking fund charges imposed upon them by their Local Act of 1885, which they intend to get modified, if possible, in the session of 1889. Under the Acts in force before 1885, the Corporation had 50 years in which to pay off the liability upon the gas-works, 100 years for the water-works, and 60 years for the loans for other purposes. But Parliament cut these periods down to 27 years, 43 years, and 35 years respectively; and the result has been an increase of £8000 or £10,000 per annum in the amount to be raised on account of the debt. This is not peculiarly a gas matter; and the administration of that department did not enter very largely into public discussion, as why should it with gas at 2s. per 1000 cubic feet? There was a suggestion that it might be wise to reduce the price to the consumers in the out-townships, and also to those in the district added to the borough under recent Improvement Acts, who are exceptionally treated in reference to some matters of rating. The fear expressed with reference to these people was that they might be driven, by the feeling of injustice done to them by the higher price they are charged, to resort to the use of oil or some other illuminant, and that thereby they will be lost as customers to the Gas Committee. One of the speakers reminded the ratepayers of the success which has attended the manufacture of sulphate of ammonia at the works since it was commenced three years ago, and stated that the Gas Committee have under consideration the question of the distillation of tar, which they believe may be undertaken with similar profit and success. They have also in contemplation a scheme for the haulage of coal from the railway to the works, which will save £600 a year in cartage. He added that in 1884, with gas at 3s. 4d. per 1000 cubic feet, the Committee made a profit of £15,168; while in 1888, with the price 2s. 5d., they made £12,178. This year the price has been reduced by 5½d., which means a loss in profit of £4500.

Two or three little points cropped up at Bolton in connection with the gas-works. The recent difference with the stokers was referred to by some gentlemen, who were anxious to convince the working men voters that "Codlin's your friend, not Short." There was also some discussion as to the reduction in the price of gas which has been made this year. Some members of the Council, it appears, thought the amount of the reduction should have been 6d. per 1000 cubic feet; but the majority declined to let the whole profit be swept away, especially as some of them believed the outside consumers would get the greater part of the benefit of such a step. A queer suggestion, that the reduction should be restricted to large consumers, seems to have been made in Committee, and was naturally a subject of animadversion at meetings of working class electors. It was boasted by the Chairman of the Gas Committee that the profits made by the gas-works since 1871, when the Corporation acquired the undertaking, would soon amount to a sum equal to the cost of the Town Hall, which, as

"loud cheers" greeted the announcement, was no doubt a costly building. In connection with the question of the stokers' treatment, it is interesting to note that, in dealing with it, one of the Councillors paid a compliment to the Manager (Mr. W. Smith), whom he spoke of as a very able man, who has saved the town no less than £15,000 in one year. There was, however, considerable mud-throwing during the contest. One speaker stated that certain members of the Council are interested in a Colliery Company which supplies coal to the gas-works (but this met with a prompt and emphatic contradiction); while another quoted the Bray pamphlet on The Gas Institute as an argument against the practice of sending the Chairman and Manager to Institute meetings. In municipal contests, any stick seems good enough to beat an opponent with; and the ease with which base insinuations are made is only equalled by the eagerness with which they are oftentimes swallowed.

Warrington did not furnish much in the way of discussion on gas matters. There was a good deal of grumbling at the price, and some references to the changes in the management which caused such an outburst a few months ago; but Warrington people have another grievance just now; and the gas-works were only occasionally spoken of.

At Manchester the price of gas was a subject of frequent discussion. Many of the candidates agreed that it is too high, and that the profit made by the Corporation is too large. As the rate to which the Committee ought to reduce the price of gas, 2s. per 1000 cubic feet was suggested—or something less, said one gentleman. Those who are concerned about the smoke nuisance pointed out, of course, that a substantial reduction of price would lead to a more extensive use of gas-stoves, with the result that the pollution of the atmosphere would be lessened, while trade would be stimulated in certain channels. There were differences of opinion, however, as to the extent of the reduction; for while some candidates were in favour of gas being sold at cost price, others held that the price should clear the cost of production, and provide a "fair business profit" on the capital outlay. The system of setting aside a large sum annually as a depreciation fund, in addition to the amount absorbed by the sinking fund, was condemned by more than one candidate for office. One suggestion, as an alternative to the reduction of price, was that the city should be better lighted throughout, and lamps put up in the dark places. The audience heartily endorsed the remark that this would be better than giving large sums yearly to the Improvement Committee, to waste on Victoria Hotels and other jobs. Nor was the question of the cost of collection overlooked. It was stated that there are 36 collectors of gas accounts, some of whom it was hinted owe their positions to the influence of members of the Council. The cost of collection was put at as much as 1½ per cent. of the amount collected; and it was argued that the work might be consolidated and the staff reduced considerably below the present strength. If pledges go for anything, both this question and that of the price at which gas is sold ought to receive attention at an early date.

In Salford there were other gas questions discussed besides those having reference to coal contracts. The case of the stokers was one of these. Among the Salford ratepayers, as among those of Bolton, there seems to be considerable sympathy with the stokers; and as this appears to exist in exact proportion to the ignorance of the facts of the recent dispute, it made a capital election cry. One speaker politely suggested that the present Gas Manager should be "sacked," and the Gas Committee dismissed; for they were endeavouring to cheapen gas, while they were slowly murdering the poor stokers! Others had, however, the honesty to plead for a fair field for the new Committee, until they have had a chance of carrying out the reforms needed in the department. The price of gas and its quality were also discussed; and reduction of one and improvement of the other were advocated and promised on more than one platform.

In many of the smaller towns, there have been reductions in the price of gas during the past year; and the clamour for cheap gas has therefore been less loud and persistent than is frequently the case. The subject has, however, not been entirely neglected; for it forms a very convenient and ready election cry. A demand for cheaper gas or better gas has therefore figured in many election addresses; but in only a few instances has the question been at all prominent.

THE LONDON WATER COMPANIES AND THE THAMES CONSERVATORS.—A correspondent has called our attention to the statement in the first paragraph of the article on "Water and Sanitary Affairs" last week, that the Conservators of the Thames receive £5000 annually from the London Water Companies, under certain guarantees for maintaining the purity of the water. He points out that this was the sum paid in 1866. It is, however, much higher now; having been raised to £12,000 in 1870, and to £18,000 last year.

NAPHTHALENE A CURE FOR DYSENTERY.—Dr. Taylor, of "Science Gossip," writing in the *Australasian*, says: "For some time past naphthalene has been a source of some trouble to gas companies generally. Now it appears as if, like all other 'waste substances,'—which are only 'waste' because we do not know what to do with them—naphthalene will come into vogue for special as well as general uses. Medical men have discovered that it is a valuable drug in cases of dysentery, summer diarrhoea, and other intestinal disorders. Injections of it have proved valuable in cases of dysentery."

WATER ACTS FOR 1888.

LAST week (p. 842) we gave an abstract of the Acts relating to the supply of water by Companies passed during the last session of Parliament; and we complete to-day the Water Legislation of the year by briefly referring to the Acts passed at the instigation of Corporations and other public bodies.

The Falkirk and District Water Act incorporates a public Trust for better supplying with water the burgh of Falkirk and neighbourhood. The Act constitutes a board of sixteen trustees for this purpose, as a body corporate, part elective. The existing water-works of the Commissioners of Falkirk are vested in the new body, who are empowered to extend them by the construction of an impounding reservoir on the Earl's Burn, another on Faughlin Burn, and two others, together with filters and accessory works, to be completed within seven years. The trustees are empowered to borrow £80,000. The Hexham Local Board (Water) Act enables the Board to construct water-works for the supply of their district, taking the water of certain springs, and distributing it from a service reservoir, under restriction as to quantity to be abstracted. The sum of £10,000 is to be borrowed for this purpose; and rates ranging from 7½ to 5 per cent. are chargeable for domestic supplies. The Hinckley Local Board Water Act authorizes the construction of water-works by the Local Board; the said works comprising means for collecting and distributing the water found in a disused coal shaft. The rate for domestic supplies is to be 10 per cent. upon the rateable value. Borrowing powers to the extent of £45,000 are conferred by the Act. The Newport (Monmouthshire) Corporation Water Act transfers the undertaking of the Newport Water-Works Company to the Corporation. The consideration for the transfer is the payment of £10,000 in cash for distribution among the "A" shareholders, and of annuities calculated as follows:—The holders of "A" and "B" stock receive 8 per cent.; the owners of preference stock, 6 per cent.; and holders of "C" shares, 1½s. per share. The Company retain their reserve fund, and cash balance on date of transfer. These annuities are redeemable—preference after 30 years, and ordinary after 20 years—at twenty-five years' purchase. New works are to be constructed within five years. For the purposes of the Act, the Corporation are authorized to borrow the various sums of £10,000, £255,000, and £4000. The Halifax Corporation Water-Works Act enables the Corporation to enlarge their works by the construction of three impounding reservoirs upon the Alcomden or Walshaw Dean Water, in the township of Wadsworth and parish of Halifax, to be completed within seven years. The Corporation are to supply water in bulk to the Hebden Bridge Local Board, at the rate of 4d. per 1000 gallons for seven years, and for ever afterwards at 3½d. per 1000 gallons. The price of water supplied in bulk to the Local Boards for the districts of Brighouse, Elland, Greetland, and Sowerby Bridge, and the Rastrick Water-Works Company is fixed at 5d. per 1000 gallons. The Corporation were, by an Act passed in 1870, authorized to borrow £300,000 for water-works purposes, of which £118,000 had been raised, and a further expenditure of £25,000 had been incurred. The present Act forbids the borrowing any more money under this former Act. For the purposes of the new enterprise, the sum of £180,000 may be raised, to be repaid in 60 years. The Hamilton Water Act authorizes the construction of additional water-works for the Hamilton Water-Works Commissioners, consisting of an impounding reservoir upon the Cadzow Burn, to be completed within five years; the sum of £25,000 being raised for this purpose. The Stockton and Middlesbrough Water Works Act amends the Acts relating to the supply of water by the Stockton and Middlesbrough Water Board, extending the period allowed for the construction of certain works, and regulating the quantity of water to be taken from the River Tees. The Act contains a clause sanctioning the payment of interest on money borrowed out of capital during the construction of the works. The Corporation of Stockton are authorized to borrow £20,000, and the Corporation of Middlesbrough £24,000 for the purposes of the Act. The South Stockton Local Board are also authorized to borrow two sums—£1155 and £4000 respectively. The Lancaster Corporation Act contains a few clauses relating to water. It provides that the Corporation may, if they think fit, refuse to supply water for domestic purposes, except by meter, and regulates the matter of compensation water. The Llanelly Local Board Act contains clauses forbidding the levying of a water rate by the Board, and charging all loans heretofore raised on the security of such a rate to the general district fund. Power is taken to establish a water-works renewal fund, to the extent of £10,000, by annually setting aside not more than £400 out of the net profits of the undertaking. The Nelson Local Board Act empowers the Board to construct water-works, impounding the Ogden Water and Black Moss Water, to be completed in ten years. The sum of £130,000 is to be borrowed for this purpose. The Perth Water and Gas Act enables the Commissioners to sink an additional filtering-well in the Moncreiffe Island of the River Tay, and to construct sundry other works, to be completed in seven years. The sum of £30,000 is to be raised for water-works purposes.

In accordance with the terms of their Act of Parliament, the South Metropolitan Gas Company have intimated to the Metropolitan Board of Works their intention to sell, on the 14th prox., £50,000 of their 5 per cent. perpetual debenture stock.

Notes.

EXPERIMENTS WITH TAR FUEL.

Mr. James Holden, Locomotive Superintendent of the Great Eastern Railway, has been experimenting with liquid fuel for steam raising. His first experiments were made upon a stationary boiler at the oil-gas works of the Company's Stratford factory. Here Pintsch's patent gas is made for lighting the trains; and one of the products of carbonizing the oil is a tar which it was difficult to dispose of at any price, but which is now successfully burnt under the boiler. These trials began in 1886. The boiler is a small one of the Cornish multitubular type, 10 feet long and 4 feet diameter, with a furnace 7 feet long by 3 feet in diameter, from which 122 tubes $1\frac{1}{2}$ inches diameter by 3 feet long extend to the back of the boiler. The boiler is worked at about 60 lbs. pressure; and when fired with coal, it consumed on an average 68 cwt. 1 qr. 16 lbs. weekly, for 79 hours' steaming. With the tar-burning apparatus, the consumption of fuel per week, for 69 hours' steaming, has averaged $454\frac{1}{2}$ gallons of tar, and 2 cwt. of coal, or an hourly average of 65.9 lbs. of tar and 3.3 lbs. of coal, against 97.1 lbs. of coal per hour under the old system. The arrangement was next tried upon three boilers of the locomotive type in the Wagon Department at Stratford; and on these its performance has been very satisfactory. The boilers are worked at 80 lbs. pressure; and the comparative results of a week's working with coal only, and with coal and liquid fuel together, are as follows:—Staveley coal, 156 cwt. for 63 $\frac{1}{2}$ hours' steaming; or 275.1 lbs. per hour, including coal for lighting up. With the coal and oil there was a consumption for 60 $\frac{1}{2}$ hours' work of 55 cwt. of Staveley coal and 546 gallons of green oil, or an average of 101.8 lbs. of coal, and 99.3 lbs. of oil (9 gallons per hour). With coal only the evaporative duty was after the rate of 7.16 lbs. of water per pound of fuel; while with the coal and oil it was 8.91 lbs. per pound of the combined fuels. Subsequently the system was adapted to a furnace in the steam-hammer shop, to a rivet furnace in the boiler-shop, to a Cornish boiler in the printing department, and to two locomotives. Various descriptions of liquid fuel have been tried. *Engineering* reports a trial run of a locomotive burning a mixture of one-third of green oil with two-thirds of tar, which was completely burnt without smoke or trouble. Roughly speaking, the consumption of fuel in this engine was 1 gallon of liquid and 14 lbs. of coal per mile. In Mr. Holden's system the liquid is injected into the furnace (which is not altered in any way) by a steam jet. The steam is supplied to the central jet of the injector, the liquid fuel surrounds it, and an air supply is disposed concentrically outside the whole. A thin coal fire is kept on the grate; and to assist in keeping the grate properly covered with the very thin fire, lumps of chalk are placed on the bars when starting for the day. The locomotives fired in this way with liquid fuel (tar), valued at 1 $\frac{1}{2}$ d. per gallon of 11 lbs., show a slight saving as compared with coal.

A NEW ROLLING MACHINE.

An account is given in a recent number of the *Journal of the Franklin Institute* of a machine for rolling iron bars into finished articles, which has been examined by a Committee of the Institute. The machine is described as consisting essentially of two dies moving in opposite directions, with surfaces that approach each other. The effect produced depends, of course, upon the form of the dies; but all act in the same way, by first rolling the ductile metal into the intended shape, and continuing the action until a finished surface is produced. The metal rod subjected to this operation is stretched in the direction of its length, in contradistinction to the shortening or "upsetting" effect of other roller-finishing machines. It is described as being the invention of Mr. George F. Simonds, and outwardly resembles in shape a steam-hammer, with the difference that where the piston would be are two vertically moving planes, like planer-beds, which by rackwork gearing move in guides simultaneously in opposite directions, rolling a heated bar of iron between them. The dies approach each other as one rises and the other descends, and are inclined from the vertical; so that, while the bar of iron does not shift its position, it rolls on its axis under the pressure of the dies, and its fibres are also extended longitudinally. In this way a plain bar of iron is formed into a screw bolt without requiring other treatment. The machine delivers work approaching lathe-turned articles in finish and accuracy. Bolts with necks of the same diameter as the bottom of the threads are easily made; and the metal is so much improved that it gains in strength and in power to resist corrosion.

ELECTRIC WELDING.

At the last meeting of the Association of Railway Telegraph Superintendents, held at New York, Mr. O. K. Stuart read a paper on electric welding, in which he remarked that, beginning with the joining of small wires of iron and copper, the process has been so successfully developed that bars of very large size and of almost any shape or kind of metal can be soundly welded. So absolutely is the heat localized when pieces of metal carrying a welding current are placed together, that pieces of 1-inch iron bar, 3 inches long, can be welded and afterwards held in the hands for some time without any danger of burning; the only heat which is felt at all being that which is conducted along the metal to the hands after the welding is completed. It is possible by the Thomson process to weld any metal, including those that melt at a very low temperature, such as lead, zinc, and tin, and those which melt at

enormously high temperatures, as, for instance, iridium and platinum. Very perfect means of regulating the heat are required when dealing with such high temperatures so quickly developed as in the Thomson process, and these are provided. A bar of 1-inch iron, 4 inches long, can in this way be raised in 20 seconds to a dull red heat, and kept at this point for an indefinite period; then the heat can be raised in a few seconds to bright red, and increased to welding or even vaporizing point in a very short time. Half-inch round iron rod can be welded in six seconds; and inch rod, in 45 seconds. Soldering, bronzing, annealing, and tempering, as well as the direct joining by fusion of different metals, can be accomplished in this way. Tubes for gas and water can be joined into one length; even the joint between iron and brass being made by fusion. A portable machine for doing light welding *in situ* is being perfected by the Company owning the Thomson patents for electric welding. The machines are not very costly; and their use is expected to revolutionize the plumbing trade.

Communicated Article.

A SPECIAL AIR SUPPLY FOR GAS-BURNERS

By NORTON H. HUMPHRYS, Assoc. M. Inst. C.E., F.C.S.

To those who, from force of circumstances, have been obliged to contemplate the subject of gas consumption from a theoretical point of view only, or from an outside position in a practical sense, the new system described in the *JOURNAL* for the 16th ult. (p. 672), under the head of "A New Combined System of Gas Lighting and Ventilation," is of marked interest. It represents a bold attempt to gather and consolidate into practical shape a number of vague, hazy, and indistinct notions that have been floating about in the brains of most gas engineers who have taken an interest in the scientific and theoretical department of gas manufacture and supply, and which perhaps date back almost from the commencement of the gas industry. The effect of diluents such as carbonic acid, air, nitrogen, and aqueous vapour, on the illuminating value of coal gas has been several times ascertained by experiment. Incidentally, the effect of the air used for the supply of a gas-flame has been noticed, though it does not appear to have occurred to anyone to make experiments in the way of a special air supply. For example, when writing on the subject of "The Commercial Valuation of Illuminating Gas" * about four years since, I remarked—

We know that if gas is burnt under a low atmospheric pressure, such as that furnished by the attenuated air on the top of a mountain, or in an atmosphere rendered poor in oxygen by the presence of other substances, the amount of light given by the flame is much reduced, though at the same time the flame is increased in size. Its intensity is diminished; but its quantity is increased. The presence of diluents in the gas itself has the same effect, of impoverishing the atmosphere in which the combustion is taking place. The result is that the gas is burnt at a disadvantage, and does not yield the amount of light it would be capable of giving under more favourable circumstances. . . . The purer the atmosphere, the less concentrated the flame; and as the flame becomes less concentrated, it gets yellowish in colour and dull in appearance.

Many similar remarks might be quoted from articles or lectures on the subject of gas consumption; but, with the exception of the practice of supplying air under pressure to burners of the incandescent class, the writer is not aware that any proposal in the way of a special air supply has ever been made. In the case of the incandescent burners, the object is to promote combustion; so that the idea of giving a separate and purified air supply, with the object of increasing the duty per cubic foot of gas consumed, is probably entirely novel.

Yet every gas engineer must have noticed at times the important effect exercised by the condition of the atmosphere upon the value of his gas. It is a matter of common remark that the street lamps burn much brighter on a clear, dry, and frosty night than when the weather is heavy, damp, and muggy. Various opinions have been expressed as to the cause of this. Barometric conditions have undoubtedly some effect; for it has been shown in several ways, since Professor Tyndall burnt a candle on the top of Mont Blanc, and noticed that it gave very much less light than when used in the valley below, that any illuminant is affected by variations in atmospheric pressure. By reducing the pressure, the luminosity can be destroyed; and, on the other hand, substances which yield a practically non-luminous flame at ordinary pressure—marsh gas, for instance—give a considerable amount of light when consumed in an atmosphere that has been artificially placed under a pressure of 60 or 70 lbs. per square inch. This being the case, it follows that a barometric variation between 28 and 31 inches, or to the extent of 10 per cent., in the pressure of the atmosphere, will have a notable effect upon the illuminating value of ordinary coal gas. Some experiments on the point would be extremely interesting. In the suggestion that the moisture which is always present in the atmosphere to a greater or less degree—and in England the "greater" usually obtains—has an important effect on the illuminating value, we have a new line of thought opened up. Speaking generally, the lower the barometer, the greater the proportion of moisture present in the air; so much so that the indications of this instrument are regarded as a weather guide—a "fall" indicating wet, and a "rise" fine weather. So it would appear that, at low pressures, the gas has not only to contend with the disadvantages due to an attenuated atmosphere, but also with those

* See *JOURNAL*, Vols. XLIII. and XLIV.

caused by the presence of a larger quantity of moisture in the air than usual.

In contemplating the subject of gas combustion for lighting purposes, and the use of fuel gases as a source of heat for high temperatures, as in retort-settings on the generator system, a remarkable coincidence will be observed. It is a usual experience that the best lighting effect is obtained from a gas-burner just as the gas is on the point of smoking. This means, when it has a sufficient supply of air and no more. The upward draught created by the products of combustion and by the escape of the gas from a gas-burner, causes a continuous fresh air supply to it, exactly as the draught of the chimney brings the air supply to a furnace. An increased pressure causes an augmented supply of air; and a burner under great pressure of supply may be compared to a generator furnace in which the damper is set too high, so as to draw in an excess of air, or to the old-fashioned grate furnace that will not act satisfactorily unless an excess of air is admitted. In the burner we decrease the supply pressure until something near to the theoretical requirement of air is attained; and in the furnace we adopt other means for securing the same end. The result is that more heat is retained in the gas-flame or in the furnace, as shown by the higher temperature obtained, and a proportionately less quantity passes off with the products of combustion. In the gas-burner, the greater temperature yields an increase of light; in the furnace, it gives us a larger proportion of the total heat in a utilizable form. The analogy also extends to the application of regeneration. The object in each case is to bring back some of the heat that would otherwise be wasted, and to use it as a means of increasing the temperature—the initial temperature, it is usually called. It is not unreasonable, then, to suggest that the improvements in modern gas-burners, by which “the duty” attainable for a given quantity of gas has been increased threefold, or, including the claims advanced for this new system, fourfold, are to a great extent due to the same cause that has led to the improved results from fuels secured by means of the generator system. In each case there has been a better adjustment of the air supply. Whereas it was formerly the rule to work with a considerable excess, this has now been reduced to very little above that shown to be necessary for complete combustion and oxidation of the hydrogen and carbon present in the fuel. When the “special air supply” system has been proved to be a success in respect to an increase of duty from the gas, apart from the other advantages it undoubtedly brings with it, it will be time to consider the application of the same system to the use of fuels on the large scale.

With the ordinary batswing or fish-tail burner, used without a globe, there is a free and unimpeded rush of air to the base of the flame on all sides. In Sugg's Argand, and to a greater extent in the various makes of regenerator burners, the air supply is to a certain degree throttled or baffled. In the Argand burner the base of the burner is very much closed in by the cone; and in the regenerator burner the air supply has to take a circuitous course in reaching the burner, while the products of combustion are also “baffled” in passing the arrangement intended to act as the regenerator. It is expressly stated that with the Methven-Sugg system the air supply is arranged to be at the rate of 10 cubic feet per cubic foot of gas. The actual requirement, according to theory, is from 6 to 7 cubic feet; so that an excess of 50 or 60 per cent. is allowed. But this, though apparently high, is a great advance on ordinary burners, all of which require a large excess of air under general circumstances, and probably so with other improved forms of burner; so that, apart from the advantages incidental to the special air supply, some considerable increase of “duty” might be expected from the regulation of the supply.

The statement that an improvement of 10 or 15 per cent. is obtainable by removing the moisture and carbonic acid from the air is striking, but, on consideration, by no means incredible. The effect of the presence of 1 per cent. of carbonic acid in the gas is known to range from 4 per cent. upwards, according to the kind of burner used; and there is reason to suppose it to be a constant quantity, irrespective of the quality of the gas, so that the poorer the gas the greater the percentage of depreciation. As to the effect of moisture, but little is known. Mr. Aitken, in a paper on “The Influence of Aqueous and other Vapours on Illuminating Gas,” read before the West of Scotland Association of Gas Managers in 1878,* remarked that the result of drying a sample of gas, by passing it over anhydrous chloride of calcium, was to raise the illuminating value from 27·24 to 27·46 candles—only a gain of 0·8 per cent. At the same time the gas was diminished in volume to the extent of 2·8 per cent. Dr. Percy Frankland† states that the effect of drying a sample of gas is to reduce its volume about 2 per cent., and to increase its illuminating value from 16·9 to 17·5 candles. In this case the depreciating effect is about half a candle, or 3·3 per cent. Dr. Frankland obtained a very similar result with ethylene—a rich gas of 70-candle power or thereabouts.‡ He also remarks that some years ago the London Gas Referees found that an advantage of 6 or 8 per cent. was obtained by drying the gas.§

The effect of these impurities, when present in the air instead of the gas, will be greatly increased, because ten times as much air is used. Under ordinary circumstances, air contains 5 or 6 grains of aqueous vapour per cubic foot. Pure air in the country contains 2 or 3 parts of carbonic acid in 10,000; but in towns this proportion is

often more than doubled. The air in the upper portion of inhabited rooms would probably contain a larger quantity both of water and carbonic acid; so that the former may be taken at 7 grains per cubic foot, and the latter at 0·1 per cent. Each cubic foot of gas, therefore, receives at least 70 grains of water vapour, and 1 per cent. of carbonic acid from the air; and in the case of ordinary burners a good deal more. This is sufficient to show the importance of extending some consideration to the question of the air supply of gas-flames.

Dr. Frankland, in the paper already mentioned, says: “That the presence of aqueous vapour in gas should tend to reduce its illuminating value was to be anticipated, since this aqueous vapour had to be raised to the temperature of the flame by the heat produced in the combustion of the gas.” Moreover, the aqueous vapour at the temperature of the flame is partly dissociated, which dissociation is attended with a large absorption of heat; 70 grains is just 100th part of a pound, and the specific heat of water vapour is 0·475. Therefore one unit of heat would be sufficient to raise that quantity of moisture to the extent of 210° in temperature. The flame temperature is very high—perhaps 3000° Fahr., so that from 12 to 15 units of heat per cubic foot of gas would be absorbed in raising the temperature of the aqueous vapour. A cubic foot of gas yields 6·20 units of heat and upwards, according to quality; so, with ordinary 16-candle gas, some 2 per cent. or more of the total heat is absorbed in raising the temperature of the aqueous vapour. This is without allowing anything for dissociation. We have no actual knowledge as to whether or not this occurs to any extent; but it is evident that such an effect, taking place just in the hottest part of the flame, would be greatly prejudicial to its light-giving power. The heat-absorbing effect of dissociation would be similar to that involved in raising the temperature of the aqueous vapour another 1000°, and, if it was complete, would involve the loss of another 5 units of heat. If we calculate the effect of atmospheric moisture as an absorbent of heat from an ordinary furnace, and the enormous volume of air that is continually rushing in to maintain the combustion, it will be seen that, as in the case of the gas-flame, the removal of this small and apparently insignificant quantity of moisture is by no means such a whimsical or chimerical idea as it might at first sight appear.

It is a singular fact that the depreciating effect on illuminating value exercised by nitrogen, air, and carbonic acid is greater than that of aqueous vapour, although their specific heat is only about one-half. The loss of heat due to the presence of 1 per cent. of any one of these constituents is very slight—not more than 7 or 8 units, or about 1 per cent. of the whole. Yet the loss of light is four or five times as much; and this seems to show that the loss is due to causes other than the mere abstraction of heat.

Messrs. Methven and Sugg are to be congratulated on having obtained, or being within fair prospect of obtaining such a remarkable duty as that of 13 candles per cubic foot of 16-candle gas—an increase of fourfold on that which was considered to be the limit not very many years ago. Practically, the effect is to cheapen gas to a corresponding extent; for if the consumer is enabled to get 13-candle duty out of a gas which formerly yielded only 3·2-candle, the effect is to render it worth four times as much to him. Mr. W. H. Preece recently estimated (see *ante*, p. 463) that the cost of producing 1000-candle power—one candle for 1000 hours—by London gas was 1s. 3d. The means by which he arrived at so high a figure are not at all clear. If we assume gas to be worth only 3 candles per cubic foot, then the cost of the 333 cubic feet of gas required would be less than 1s. With the Methven-Sugg system, however, the cost would be reduced to less than 3d., seeing that about 80 cubic feet of gas would be sufficient. So it is time for electricians to amend their estimates. Another point for congratulation is that the improvement already realized—an increase of fourfold—may well encourage us to be hopeful as regards the future. It has been repeatedly pointed out that only a mere infinitesimal portion of the total force produced by the combustion of gas is really obtained in the form of light, and therefore that there is a large margin to be worked for improvement—so large that the advance already obtained, important as it is in a practical sense, is really of comparative insignificance. But this advancement, such as it is, gives some promise of future progress.

The fact must be faced that a special air supply, and the removal of moisture and carbonic acid therefrom, means extra expense. But the advantages secured are such as to be more than sufficient to compensate for the cost of obtaining them, apart from any consideration as to increased duty from the gas. Rendering the gas combustion absolutely separate and independent from the atmosphere of the apartment at once secures everything in the way of pure air, long life, &c., that has been claimed for electricity, and does away with the prejudice sometimes exhibited in regard to the effect of sulphur compounds, supposed incompletely consumed constituents of coal gas, and the products of combustion generally. It also opens up a means of arriving at what has never been really obtained before—an absolutely reliable system of ventilation, that may be equally depended upon under all directions and degrees of force of wind, and other climatic conditions. In this respect it has a distinct advantage over the electric light, which, at the best, is only a “neutral” in the matter of ventilation.

THE HALIFAX GAS COAL CONTRACT.—Our readers will see, by an advertisement which appears elsewhere, that the Gas Committee of the Halifax Corporation have decided on inviting tenders for cannel coal, in substitution for that which was to be supplied under the contract of Mr. Wrigley, of Ashton-under-Lyne.

Technical Record.

SOUTHERN ASSOCIATION OF GAS MANAGERS.

THE DISCUSSIONS ON MESSRS. LIVESLEY AND PRICE'S PAPERS.

Last week we gave the text of the two papers read by Mr. George Livesley and Mr. W. E. Price respectively, at the quarterly meeting of the Southern Association of Gas Managers, held at the Hôtel Métropole, on the previous Thursday, and to-day we publish a full report of the discussions.

MR. LIVESLEY'S PAPER—"THE GUIDE-FRAMING OF GASHOLDERS: HOW AND HOW FAR MAY IT BE DISPENSED WITH."

(See *ante*, p. 846.)

The PRESIDENT said the members had before them a novel theory in the matter of gasholder construction; and he expected there was not anyone there who was able to give them the result of any really practical experience upon this subject, except in the case of the Rotherhithe holder. There were, however, many present who would be in a position to criticize the matter from a theoretical point of view; and he was sure that they would have a good discussion, which would tend to enable them to come to a clear understanding as to whether Mr. Livesley's system could be carried out economically enough to be substituted in place of guide-framing.

MR. LIVESLEY said he hoped every objection that gentlemen present could think of would be urged, as he was not himself particularly partial to the idea.

MR. W. H. H. BROADBERRY (Tottenham) thought the thanks of all the members were due to Mr. Livesley for the able manner in which he had placed this question before them; but those who knew Mr. Livesley were not at all surprised at that. On the question of the method of guiding gasholders, he did not know that there was anything practical to be said upon the matter. It seemed to him that Mr. Livesley had mentioned all the points that it was possible to discuss. As to erecting gasholders without guide-framing, it really came to the question of cost. Personally, he could not at present see that there was much advantage to be gained by dispensing with the old-fashioned guide-framing, though he must admit that it was possible to improve the latter. The present method of guide-framing seemed to him to be very simple; and up to the present time it had proved efficacious. If, however, it was at any time necessary to build a gasholder where there was no room to put up guide-framing, then they could use one of the ingenious plans which they had before them—either Mr. Livesley's or Mr. Gadd's arrangement. Under these circumstances, there was no doubt that they would prove very useful; but it seemed to him that if they had room for a gasholder to rise, it only required a little more space for the guide-framing to be erected. He should have more confidence in the good old-fashioned guide-framing than in Mr. Livesley's idea. It appeared to him that if the strain was taken away from one place, it must be put on another—that was, on the sheeting and bottom curb of the holder. In any case, they would no doubt have to considerably strengthen the bottom curb; and on the question of dispensing with the upper guide-framing of a three-lift holder, it appeared to him that they would have to strengthen the curbs and cups to prepare for it. He did not know whether or not this was so. The question naturally arose, Where was the saving to come in? Unless they could show that there was to be some saving—unless they could show they would get more for their money—he did not see where the special advantage would occur. At any rate, on the question of gasholder building, they knew that there were really very few who would be able to try experiments in this direction. Mr. Livesley was rather a bold man, and no doubt he liked to depart from trodden paths. As a proof of this they had the experiment at Rotherhithe. This holder appeared to work very well; and he hoped it would continue to do so. He must, however, confess that, unless he saw something more than he had done up to the present, if he had to build a three-lift holder, he should run the guide-framing up to the top. If ever necessity arose to put up a holder without guide-framing on the outside, he would then consult either Mr. Livesley or Mr. Gadd, and see what they could do in the matter. He must acknowledge that he had a prejudice for the old-fashioned outside framing.

MR. C. GANDON (Lower Sydenham) considered that the paper was a most important one. Personally, he had very little to say upon the matter; for as he had not had any practical experience in building holders without framing, it could only be pure speculation. He read with considerable interest, and he hoped with some little advantage, the admirable articles, to which reference had been made in the paper, that appeared in the JOURNAL by "Theory and Practice." Although he had had some doubt as to the possibility—or desirability, at all events—of attempting to work any portion of a gasholder without guiding it, he must confess that these articles convinced him that it could be done, at least so far as the upper lift of a three-lift holder was concerned. If any gentleman present had not read the articles, he would strongly advise him to do so; and he trusted that the suggestion contained in the paper, that they should be printed in a separate form, would be carried out, for they were the most interesting contributions they had on the subject. But these ideas—both Mr. Livesley's and Mr. Gadd's—were entirely different from what he had gathered from the articles. That any one could raise the upper lift of a three-lift holder without guide-framing was, to his (Mr. Gandon's) mind, satisfactorily

proved by the articles, and still more satisfactorily demonstrated by the Rotherhithe experiment. He had seen the holder there at work and fully inflated; and it seemed to him to be perfectly safe. As to these spiral or zig-zag guides, he was bound to confess that he did not know how they acted. Mr. Livesley had mentioned the matter to him some weeks previously, and he had since read the paper; but still he did not quite understand it. He could not see what there was to prevent the holder tilting or jamming. With Mr. Gadd's spiral guiding, he could see it more clearly. Possibly it was only his obtuseness that prevented him comprehending the principle. Mr. Livesley's plan was probably a modification of Mr. Gadd's spiral; but he certainly could not understand how it would prevent tilting. There was also this question for consideration—How far would they have to strengthen the holder to resist the strain which might be thrown on it by doing away with the framing? One difficulty in designing a large gasholder was to prevent it from causing too great a pressure. If they had to strengthen the holder, they would have to put more material into it in order to resist these strains. He did not therefore see that much economy would arise. He fully shared Mr. Broadberry's views in this respect, for he had a conservative feeling and a singular affection for the old-fashioned guide-framing; and if he (Mr. Gandon) had to put up a holder of any considerable dimensions, he should adopt the old method of guiding it. He should like someone else to make an experiment with the new style first. He thought the plan was feasible, and there seemed to be a considerable amount of theory to back it; but he should continue to prefer guide-framing until the new system had been proved. He saw in the illustrations that the projections on the guides were angular. Would it not, he asked, be better in practice that they should be rounded off?

MR. LIVESLEY: You will see that we have experimented with one that has been rounded.

MR. GANDON: Partially rounded; but he thought it might be more so. He could only offer his own views upon the question before them; and, in conclusion, he would again say that until the idea was proved, he should stick to the old framing.

MR. C. E. BOTLEY (Hastings) said that the same ideas had occurred to him which had been expressed by Mr. Gandon. He also thought there would be a tendency for the holder to jam or tilt with the proposed plan of guiding it. He also asked Mr. Livesley to explain the working of his single tangential roller in the guides. If this system would reduce the cost of erecting gasholders, it would be a very great boon. But when they knew that it would be necessary to considerably strengthen the bottom curb and the holder altogether, it was trying an experiment which might not succeed, while at the present time they had a fairly cheap and satisfactory way of guiding holders. What diameter holder, he asked, did Mr. Livesley or Mr. Gadd say could be worked upon with this system of guiding? He had just been designing a new three-lift holder of rather small diameter (about 100 feet), as they had not much ground available on the site; and he was considering whether he would not do without the framing to the upper lift. But he thought it would not be well to risk it for so small a holder. He should like to know whether or not Mr. Livesley's or Mr. Gadd's new system of guiding would be applicable to a holder of small diameter.

MR. W. D. CHILD (Romford) remarked that Mr. Livesley had taken those present into his confidence so thoroughly in regard to his invention, that he (the speaker) thought it was only right on their part to return the compliment by expressing the slightest difference of opinion which they might have regarding the matter, so that one and all might have the benefit of it. They might be in error; and the correction of it would set them right. There was one thing they had to look at in the construction of holders on this principle. Taking it simply as a single-lift holder, he did not see exactly any reason why the strength of the holder should be in any way increased to deal with a question of this description. Mr. Livesley was attempting to control the movement of the holder by gripping the bottom lift; and therefore the sides, it appeared to him, would be entirely in tension. The only thing that occurred to him was whether the projections of the guides were not too sharp—that they would give, as it were, a jerky movement to the holder in rising and falling, and rather a tendency to set itself fast. If it would work without any difficulty and with smoothness, it appeared to him that the system would effect a considerable saving, in the cost of both the holder and the tank, because anyone who had had experience in excavating tanks must have seen that the cutting away of the extra diameter where the piers were required, was frequently a source of great difficulty, and was more likely perhaps to bring about a fall of earth than when making a regular circular excavation.

MR. W. H. Y. WEBBER (London) remarked that there appeared to be some little hesitancy on the part of the general body of members to discuss this question. He thought this might be largely due to the fact that there was some misapprehension in the minds of a good many as to what was the exact scope or object of the various ideas put forward. When trying to imagine how a gasholder could be erected without any guide-framing at all, it was his idea that the real object was the pursuit of truth with regard to the principles governing the stability of gasholders. The first consideration was not so much whether or not they were going to save a few pounds in the construction of a gasholder of given dimensions. They wanted to get at the truth of the conditions governing the stability of the holder; and then if they once found this datum, it followed that they could go on building holders as high

and as large as they liked. Then the question of economy came in. Mr. Botley had made an inquiry in reference to small holders; and he (Mr. Webber) might remark, with regard to small holders, that it was easy to try experiments with them, although the saving might be comparatively slight. He would ask those present to carry their minds a little back to the time (say) when gasholders were always built with very massive cast-iron columns—some fluted and gilded, and all that sort of thing; and the only idea of holding the columns up was an ornamental horizontal girder at the top. The natural consequence of this order of ideas was that there was understood to be a limit in the size and height to which holders could be safely carried. The result was that sometimes when additional storage was wanted, extra ground had to be bought, and another holder put up; whereas if inquiry had been more thorough into the conditions of stability, the existing holder would have had another lift, or even two or three lifts, added. He did not know how many lifts Mr. Livesey thought his holders would bear; but it appeared to him (Mr. Webber), judging from the way in which he was going on, he would make them something like one of those tourists' telescopes of manifold slides, which could be drawn out to an extraordinary length. There was, of course, a good deal of criticism, on suggestions of this kind which was—if he might use the term—comparatively cheap. It was very easy for anyone to say they did not like this sort of thing, and that they would not care about being the first to try it. They would be without gas altogether if everyone had always gone to work in that spirit. With regard to the principal saving effected by the adoption of any successful method of doing away with the superior framing of gasholders, he thought Mr. Newbigging's paper read before the Manchester Institution should be mentioned in connection with any discussion of this subject. He considered that this paper very fairly showed where the economy was likely to come in. A special point was the saving that would be effected in regard to holders intended for export. The matter had only to be mentioned to show what a wonderful difference there would be in this respect, especially if they had to send gasholders inland in places where only horse or caravan carriage was available. A holder of any size could be despatched to any place with comparative ease, provided there was no guide-framing to carry with it. He agreed with Mr. Child in the opinion that there need not be any necessity for greatly increasing the strength of gasholders. If they were to be stayed only from the bottom, it might be so; but this was one of the points which had to be proved. The diagram which Mr. Livesey had included in his paper, from those very able articles to which he had referred so abundantly, certainly showed that the stresses increased as the guide-framing was cut down; but he did not think they showed that the stresses surpassed the point which they might be permitted to attain. He (Mr. Webber) was not altogether certain on this matter. The stresses would be much greater, but were they excessive? He did not think they were; and he considered that Mr. Child was quite right on this point. The matter was entirely open for discussion now. Nobody could say very much about it one way or the other. Whether or not the thing succeeded, there were numbers of gas managers who would not reconcile themselves to it, and who would continue to profess that they would be able to retire to rest more comfortably if they were able to rely upon the old guide-framing. Some of them might be disposed to laugh at this timidity. But he thought there was quite as much reason for it as some engineers had for not believing in telescopic holders at all; and it was notorious that there were some clever engineers in the world who had not been able to reconcile themselves to the idea of a telescoped holder. Meanwhile, however, he protested against suggestions of this or any other novel kind of thing being condemned by the mere prejudice of those who could only say they did not like them, and would be more comfortable under an old system.

Mr. F. S. CRIPPS (London) said he was pleased that he had been invited to the meeting, for he was glad to have an opportunity of hearing Mr. Livesey read his paper. It was certainly a very practical paper—at any rate what the author had said was put in a very practical and clear way. Mr. Livesey had stated at the commencement that a copy of the paper had been supplied before the day of meeting; but unfortunately it had not been sent to him (Mr. Cripps), or he might have criticized it to greater advantage. He agreed with practically everything that Mr. Livesey had said; but the question of the zig-zag kind of guides was one that required to be very closely looked into. If he might make a criticism, it seemed to him that the holder would have a jerky motion in going over what perhaps he might call the "corners" of the guides. He would therefore suggest that these should be made easier. Mr. Gandon had alluded to the same thing, but in a different way. Presuming, however, that they could get a gasholder perfectly level, and cause it to rise perfectly level throughout, what had they to gain by it? This system of constructing gasholders without any guide-framing might possibly be more economical in first cost; but that would depend upon the quantity of material they were going to use. If they increased the strains coming upon the holder, they must increase the weight of metal they put into it; and this would counterbalance some of the saving obtained. The question was, in doing away with the whole of the guide-framing, how much were the strains increased? Mr. Webber and Mr. Child did not think that the strains would be very much greater; or, in other words, that the extra strains would not make it necessary to put much additional material into the holder. He (Mr. Cripps) could not altogether

agree with them. Mr. Gadd had on a previous occasion said that the sheeting of a gasholder was of no importance at all as regards resisting the strains—that it depended entirely upon the framing. Mr. Gadd likened it to an umbrella, the cover of which might be thrown away, trusting to the framing to resist all the strains. Taking it for granted, then, that the sheeting could be disregarded, as far as resisting the strains was concerned, What had they left? A fragile frame, consisting of a series of horizontal rings one above the other (curbs, cups, &c.), and connected together vertically by a number of vertical posts (guides) all round the circumference. Now, even supposing they looked upon each of the horizontal rings as incapable of distorting out of shape, and that they would retain their circular shape under every condition, the whole frame was not even then by any means rigid; it was unstable, because it was made up of a series of parallelograms, which could all rock over sideways together, without altering the lengths of their parts. The only thing which prevented them doing so was the assumption that they were perfectly fixed and rigidly attached at the base, and that the holder was considered, for argument's sake, to be as good as standing upon solid ground. In order to be rigid, it must be a series of triangles; and to get this they must introduce into the gasholder a system of diagonal ties between the vertical posts all round the holder. This could not be done, as the space between the sides of the various lifts would not admit of it. So they must depend upon the sheeting fulfilling the function of the diagonal ties. But the sheeting could not do so, owing to its curved form between the stays, because under diagonal stress it would at once straighten across the corners, instead of resisting the force. It came to this, then—that they could not have diagonal ties, and they might not rely upon the sheeting. Therefore, the simple framework had to take all the strains. To show how incapable it was of doing so, he would take an actual example. Take a gasholder 200 feet diameter and 120 feet high. The size of the guides in the outer lift would be about 6 inches by $3\frac{1}{2}$ inches by $\frac{1}{2}$ inch channel iron, or (say) 8 inches by $2\frac{1}{2}$ inches by $\frac{1}{2}$ inch; and there would be (say) 44 in the circumference. Now, as they assumed the horizontal cups, curbs, &c., to be rigid rings, incapable of deformation, the force (due to wind pressure) would be equally distributed over the whole of these vertical posts, and would tend to break them all short off at the base. The breaking load of all the 44 channel-guide, 120-feet high cantilevers, taken together, was only about 13 tons (uniformly distributed). The safe load would only be one-fourth of this—say, 3 tons. Now, no one would contend that the wind pressure on the side of a gasholder 200 feet in diameter by 120 feet high did not exceed 3 tons. Why, at 10 lbs. per square foot only, it would be 10 tons! Therefore, they must depend upon something else beyond the guides, or increase their strength, which meant weight. If they put in Mr. Gadd's diagonal guides, they would probably in a measure act like diagonal ties; but they were curved, not direct-acting, and would need vertical posts as well to make the bracing continuous. Otherwise it would be like a girder with the lattices all one way. He thought that even then there would be a good deal of twisting and distortion of the gasholder bell, especially when they considered he had been treating of only one set of strains upon the holder. There were other matters which could not be ignored; and even what he had already dealt with were based upon such very favourable conditions (perfectly rigid cups, &c.), by no means tenable. It seemed to him to be forgotten that the higher they went into the air, the greater were the strains. Mr. Child had remarked that it made no difference how high a gasholder was.

Mr. CHILD said he should like to disclaim this at once. He went straight to the principle of guiding a bottom lift of a holder the whole way. He was not speaking specially of a one, two, or three lift holder.

Mr. CRIPPS said he had misunderstood Mr. Child. If they did away with the guide-framing to a single-lift gasholder, they increased the strains on the bell fourfold; with a two-lift holder, they would have 16 times as much strain; while with a three-lift holder, without guide-framing, it would be 36 times as much as in an ordinary single-lift holder of the same diameter and depth of lift. The lower lift of a gasholder had the most strain; the next, less; and the top one, the least of all. No one who had advocated the total abolition of guide-framing had as yet shown scientifically that the guide-framing could be abolished altogether. Mr. Livesey had abolished it for only one lift—viz., the top lift of the Rotherhithe gasholder; but he had not gone so far as to do away with guide-framing entirely in a three-lift holder.

Mr. LIVESEY. And I am not going to try.

Mr. CRIPPS (continuing) observed that before the system of no guide-framing was really brought out, it should be shown theoretically and scientifically that it would work—not simply brought forward and said that it could be done. It must be proved, just as he could prove to the contrary. When this was done, possibly they might launch forth into making gasholders without guide-framing; but not till then.

Mr. CUTLER (London) expressed his satisfaction at having been invited to be present to hear this interesting paper of Mr. Livesey's. Of course, the idea of erecting a gasholder without guide-framing was quite contrary to the traditions of the gas engineering profession, and there was no experience to bring to bear on it. It did not require any argument or mathematical investigation to prove that if a holder had to rise and fall without guide-framing, the strains which in the ordinary way were taken up and resisted by the framing, would have to be borne by the holder; and it seemed

to him that they needed proof to show the advisability of putting this additional work on a vessel designed for a different purpose than that of resisting such forces—viz., that of containing gas; and therefore of necessity it should be kept in a condition not likely to allow of its escape, and therefore kept as free as possible from unnecessary straining. The experience of the past proved the advantage of framing; and for his part he was unable at present to see any possible advantage in attempting to do away with it. Mr. Livesey had referred to the experiment at Rotherhithe; but he (Mr. Cutler) could scarcely agree that the fact of this holder working all right demonstrated the advantage of doing away with the upper portion of the framing, although it certainly proved the possibility of so doing. Was not the holder and its framing exceptionally strong? and was it proved that the additional strain coming on to the bell might not be detrimental to it as a gasholder? With regard to the idea suggested in the paper, he had not had an opportunity of seeing the paper before he came to the meeting; but certainly he was exceedingly doubtful as to the successful working of such a gasholder. Its condition had been described as if it were locked or fastened at the bottom, and thus unable to tilt, and as if it were on the solid ground, when, of course, it could not be made to tilt. But, he asked, was not such an idea contrary to the proper conception of what a gasholder is—viz., a bell freely floating on the gas which it contains, and giving to the gas a pressure equal to its weight. If the holder became locked at the bottom its weight would be more or less supported, not by the gas, but by the slanting guides on which it worked; and what sort of influence would this have on the pressure-gauge? He should be glad to have some explanation on this point. One portion of the gasholder—viz., the bottom curb—he was glad to observe was now receiving more like the attention it deserved. Engineers had hitherto seemed very much to overlook the importance of this member of the structure. For his part he did not remember ever to have seen a bottom curb really of sufficient strength in large gasholders. In his opinion, too much importance could not be given to the bottom curb, and to the lower guide-wheels, which should always be carefully adjusted, and receive much more watchfulness than was frequently the case.

Mr. W. GADD (Manchester), on the invitation of the President, said he found it was somewhat difficult to speak generally upon the paper before them. He did not know that he ought to do this under present circumstances, because it would not be necessary for him to deal with the special propositions put forward by Mr. Livesey; inasmuch as there had been a great amount of discussion thereon amongst the members. He would like to say one thing, however, relating to his own experiments. He had tried the effect of his spiral guides going short distances and returning and spiralling the opposite way. It seemed to him to be something very like what Mr. Livesey proposed to do. He showed a modification of this idea in one of the models which he exhibited at Doncaster at the meeting of the Manchester Institution. Those who were present would remember that the lift travelled in one direction—

Mr. LIVESY: But each lift travelled all its height in the same direction.

Mr. GADD said this was so; but it was a modification of the same idea as was shown at Doncaster. He found that there was a little jump or jerk; and he took it that it was accounted for in this way: However slowly the lift might be going, there was sure to be a certain momentum acquired. This had to be overcome; and when they came to the return, it had to be acquired in the contrary direction. To go to the more general principles, which had been mentioned by the various speakers, of dispensing with guide-framing, he thought, with all deference to those gentlemen who naturally felt that they would like some one else to try the experiment—they all liked this—it was, at any rate, not the way in which important improvements had been effected. The great improvements they had seen in the past had always to be brought about by someone making the trials and risking something. Of course, it would be quite improper, as Mr. Cripps had pointed out, to undertake a practical experiment without knowing something about the theoretical stresses, and satisfying one's self beforehand that there was a firm foundation to build upon. He had listened very attentively to the part of the discussion in which Mr. Cripps engaged, because he had a great respect—to put it in the mildest form—for that gentleman's opinions and for his knowledge of such matters, which he (the speaker) recognized as very considerable; and therefore Mr. Cripps would probably excuse him for slightly dissenting from his description of his (Mr. Gadd's) views. It was perfectly true that he tried to liken a holder to an umbrella covered with light canvas; but it was also perfectly true that he (Mr. Gadd) did not exactly say that he would let the sheeting go to the winds. What he did say was that, in designing a holder, it was wise to have the framing sufficiently strong to carry the sheeting, which nevertheless had its own work to do, and was, after all, most necessary to the strength of the structure. It seemed to him that a holder without framing was subjected occasionally to all possible strains at once. This would be dangerous. First of all there was the strain of distortion—that was, as he took it, the tendency to get out of true shape. The second, which to his mind was the most important thing to be considered, was the possibility of what he would call the shearing strain—that was, the possibility of bending over. Now, if the holder would resist this shearing strain, he contended that it was strong enough for any pressure to which it could be subjected, because he believed if it would resist the shearing strain, it would resist distortion; for the simple reason—that at present a gasholder was subjected to the

chance of distortion, though it was held against the guide-framing, because if there was power enough in the wind, it surely went without saying that it could crush up one side against the guide-framing and thus distort it. Now, if it was at present strong enough to resist this strain, it would be strong enough, under any circumstances, without the framing, to resist distortion *per se*. Then came the necessity for resisting the possibility of shearing over. So far as the comparison of a holder with its edges resting on the solid ground went, the proposal he had made—of spiral framing—did compare therewith, to this extent, that the holder was held at its edges, and kept horizontally, the edges firmly and solidly gripped at every possible height as it ascended or descended. It therefore appeared to his mind that—he did not purpose going into any of the minor details—the only possibility of destroying a holder was by shearing action, because it was impossible to move it out of the horizontal without breaking the bottom rollers or guides. His holder worked equally well with three rollers as with six or more. So long as there were three sound bottom rollers—not necessarily in an equal sided triangle—his holder would work up and down all right. If the present make of holders was not sufficiently strong to form in themselves huge cantilevers of sufficient rigidity, they would require to be strengthened up to that point; but not necessarily by adding weight. As regards weight of material, it was in the main quite strong enough. He was perfectly free to admit that it might be necessary to alter the form or disposition of the material somewhat for the purpose. Mr. Newbigging, in his paper, suggested that the stays should be in the triangular form, at or near the bottom curb of the holder. This, he thought, would give the requisite strength; and, furthermore, the spiral guides necessarily formed an arch or bow which must strengthen the holder against distortion. He was convinced that if it could be demonstrated that a stable holder could be made, the economy would necessarily be great; and this had been incidentally shown by one of the previous speakers, when he mentioned the cost of the foundations of the piers, and so forth. This was a very important matter indeed. They had, by the system proposed, a simple, plain tank, without counterforts. The guides could be either built into the tank or be attached to the sides in any way which the engineer designing the tank thought best. If it was true that something like 50 per cent. of the weight could be taken out of the total structure, it must, of course, make a large reduction in the cost. He took it that this was a question which must not be lightly disposed of—that this possible saving could not be ignored. He did not know that there was anything more he particularly desired to say on the subject. He would only mention that the two models of holders on his system that he had in the room were not so perfectly constructed as he should have liked them to be. However, they were sufficient to show how the system worked. With regard to the fitting of the rollers on the guides, he had purposely left them very loose; his object being to show that, with loose-fitting guides, without the necessity of anything tight at all, the thing would work. Of course, in practice on a large scale, they would be made just as tight as was found necessary for the purpose.

The PRESIDENT said he noticed Mr. Henry Woodall, the President of The Gas Institute, in the room; and he was sure all present would be pleased to hear a few remarks from him on the subject under discussion.

Mr. WOODALL said he had only just come from Birmingham, and had not had the pleasure of hearing the paper. He was not prepared to say much of consequence on the question, because, as they were all aware, he had been out of office, and had not had any opportunities of inquiring into the particular aspect of the question which was at the present time engaging the attention of the meeting. Although he could not offer any technical suggestions, he could speak of his experience with gasholders, and give one or two illustrations which would have some interest in connection with this question, and might possibly be of some value. Looking at the matter from the light afforded by his experience, he might ask whether it was not a fact that the holder often supported the framing, rather than the framing the holder. That the framing of holders had ordinarily been built very much stronger than was needed, he had been convinced for many years past. He was the more assured of this from an accident which happened to a large two-lift holder at Leeds, when, in consequence of the upper lift being frozen (gas being delivered from it at the time), the holder fell with such a crash that the sudden vibration caused a fracture of every one of the 16 columns, 3 feet in diameter. He applied four straps of wrought iron to each column, each having two bolts above and below the fracture; and in this way the holder, 150 feet in diameter, lasted several seasons—until he had it converted into a three-lift one. This was only one of two or three cases of the kind he might mention, though perhaps not so distressing. That holder only cost £5 for patching.

Mr. LIVESY asked if the holder had diagonal bracing.

Mr. WOODALL replied that it had not. They were cast-iron columns, with two tiers of girders. Then in course of time he dispensed with this framing, and used very light wrought-iron framing. These holders had been characterized as "gossamer" structures, that would not stand a gale. It so happened that the first of the six holders he put up was met by a very severe gale before half the bolts were tightened, and it stood perfectly. If any of the gentlemen present went to Leeds, they would see some of the lightest possible structures. He had never heard of the slightest difficulty with them, although there were ten three-lift holders there.

The PRESIDENT said the discussion had been very full and interesting. Some of those who had spoken were very conservative, and some very radical; and he supposed that between the two they would find the answer to the great question before them. It seemed to him, as Mr. Woodall had said, that they had in many of the gasholders round and about them too much work in the portion of the structure which held the holder in position. On the other side, he thought that when they came to construct gasholders on the system demonstrated by Mr. Livesey and Mr. Gadd, they would require to have a great deal more strength in the lower part of the structure.

Mr. LIVESSEY, in reply, said that he had been extremely interested in the discussion that had been carried on so ably by so many of those present; and he really felt there was very little to say. Perhaps it would be better to take the remarks *seriatim*. Mr. Broadberry thought it would be necessary to strengthen the cups. Well, he did not think the use of tangential rollers had been sufficiently appreciated. By their use, the strain was applied in such a way that the cup was in the best position to resist it. Where they had radial rollers, they by their bearing on the guides tended to push the cup inwards; but with tangential rollers, the stress was in a direct line with the cup in its strongest position. That was a source of additional strength, or rather it removed a cause of weakness. In regard to their friend's anxiety as to the strength of the unsupported holder, the experience of the President of The Gas Institute seemed to show that the framing used in years gone by had been stronger than was necessary. That extraordinary experience of his showed that a holder would work safely with very weak framing indeed; and therefore, if they were to assume that by the abolition of framing they might have to strengthen the holder, it did not at all follow that they must put as much strength into the holder as was now found in the framing of ordinary holders. It was shown by experience that the framing was stronger than was necessary. Mr. Botley raised an important question about the tilting or wedging; and he wished to know how these new guides of his worked. It was a difficult matter to explain how the thing worked; it was necessary that each one should think it out for himself. Of course, in practice, they would have a series of these guides extending all round the tank—perhaps a score or more, and all placed, as he had said in the paper, in exact correspondence. Thus, the projections and hollows of all the guides would be exactly at the same level. Consequently, when the holder was going down, supposing the rollers to be in the top hollows of the guides, all the rollers must move in the same direction, (say) to the right, until they passed the projection. They then moved to the left, then again to the right, and so on. Of course it had to be proved whether the thing would tilt or wedge. He had been experimenting, but unfortunately had not had time to carry out the experiments thoroughly; but so far as they had gone it seemed that, while tilting to the extent of an inch or two might take place, in practice there was no danger of wedging. He was about having a model made. If it succeeded, he would show it at the next meeting; and if it failed, he would explain why it had done so. A radial roller would work straight up these guides in the clear space of 6 inches in the middle between the projections; but as it might possibly catch against the projections, they could have a channel-shaped groove or recess cast in the centre, which would provide a suitable path, 6 inches wide, for the radial roller. Perhaps he had better say that he was not going to recommend anybody to adopt this system. As was well put by Mr. Webber, this was a discussion on a principle; and what they wanted to do was to settle sound principles. Mr. Botley's question as to the size of holder adaptable to the system referred more to doing away with the upper framing, or employing a shortened framing. He (Mr. Livesey) did not see why that should not be applicable to gasholders of any diameter; and he was not at all sure that they would not be safer for small holders than large ones, because small holders were relatively stronger than large ones to resist distortion. Mr. Child said there was no reason for increasing the strength; and Mr. Cripps had dealt very exhaustively with the matter. For a single-lift holder, he, like Mr. Child, did not think it would be necessary to increase the strength of the sides at all. He must say that so far Mr. Cripps had proved his point, that to leave two lifts unsupported would cause greatly increased strains on the sides, and to leave three lifts unsupported would be quite out of the question. He could not but believe that the strains would be very considerably increased on the side sheeting if entirely unsupported by guide-framing. In this connection he could not do better than again recommend those who had not done so to study those able articles by "Theory and Practice." He must make one remark on what had been said by Mr. Webber. He said that Mr. Newbigging's paper ought not to be passed by without mention. With that he (Mr. Livesey) quite agreed. The paper was very interesting, and dealt with a part of the subject which was of great importance. In that paper was shown the proportion which the framing bore to the bell; and hence the argument, seeing that the framing bore so large a proportion to the weight of the holder, if they could do away with the framing there would be a considerable saving effected. Mr. Cripps asked whether it would not be better to make those projections easier or more rounded in his (Mr. Livesey's) guide. In one of the sketches in the paper, they were shown easier; but that was really a matter of experiment. It had to be found out what kind of curve in the guide would be most suitable for the purpose. The specimens handed round for inspection merely showed the principle. Mr. Cripps spoke about

the possibility of a jerky motion with this guide. Possibly there might be a slight jerky motion, but that also had to be proved. He did not think there would be any difficulty on this score whatever. Mr. Cutler had spoken about the Rotherhithe holder being a holder of great strength. It had, he confessed, heavy guide-framing; but he did not call it a strong holder at all.

Mr. CUTLER: The bell of the holder is strong.

Mr. LIVESSEY: The holder has strong roof framing and sheeting; but it is not uniformly strong. But the guide-framing was not at all strong, apart from its great weight, to resist the strains that might be supposed to come upon it. He was sure that if they were going to build a three-lift holder, and to stop short at the second lift, they would put up a much stronger framing at less cost and weight. As he had explained, the holder (imagining it to be standing on the ground) with the new form of guides, was held down at the sides, and was supported from its crown by the pressure of the gas on the crown; and by Mr. Gadd's plan and his own it was held down at the sides. If Mr. Cutler was right when he spoke about the bottom curbs being weak, it was a difficult matter to make a bottom curb very strong, as its width was restricted. But the same object could be obtained by increasing the number of rollers or points of support, or by using tangential rollers. By doubling the rollers, and thus reducing the distance between the bearings by one-half, probably the curb would be strengthened fourfold; and, paradoxical as it might seem, they might thus reduce the weight of the curb very materially, and yet increase its effective strength. He had not any comment to make upon Mr. Gadd's remarks; but he must say he did not think he had answered Mr. Cripps in relation to the question of distortion of the sides of the holder. He spoke of the shearing action; but it appeared to him (Mr. Livesey) that the wind-pressure on the holder must tend to distort and buckle it; and until that was proved not to be so, he would be a very rash man who would build a three-lift holder without any framing at all. Another thing occurred to him. He did not think the sides of the holder were sufficiently rigid to fix the guides to. They might well be fixed to the tin sides of a model; but that was not like a gasholder. There was no relative proportion between the two. If they were to fix spiral or his guides to the thin sheeting of a gasholder, and depend entirely upon them, it would not be sufficiently rigid to resist the strains that came upon it. If these guides, on the other hand, were fixed to the tank, they had there a perfectly rigid support; and the rollers on a strong bottom curb could not disturb the guides. But if they fixed the guides on the sheeting of the holder, he was very much afraid that it would spring and give way under the strains that would come upon it in a holder entirely unsupported by guide-framing. His idea was this: As to doing away with the framing altogether, he had never thought of it; and from all he had seen and heard, he did not think it would be advisable or practicable. The more he thought of it, the less he considered it would be safe to abolish the framing altogether. He should think it would be practicable to build a three-lift holder with guide-framing one-lift high, and to adopt for it Mr. Gadd's or his own guide. Of course, he should naturally prefer the latter. The inner and second lifts would be guided till they cupped by radial rollers working up the centres of the guides; and with two series of tangential rollers on the outer lift—one on the cup and the other on the curb working in the corrugated guides—he thought the bottom lift would be perfectly rigid and safe; and the two upper lifts, if they were strong enough to resist the distorting action, would also be perfectly safe. That he might tell them, was the utmost to which he thought it would be safe to go. He was much obliged to them for the patience with which they had listened to the paper; and he could only hope that the result would be that it would help to settle what were the true principles of gasholder construction.

Mr. PRICE'S PAPER—"SOME HINDRANCES TO THE SALE OF GAS."
(See *ante*, p. 847.)

The PRESIDENT said he was sure the members were all pleased with the interesting paper they had just heard. They had in the first paper economy in the construction of gasholders; and now they had had shown to them the benefit which would come to gas companies if they extended their business into small cottages. Much might be said on the various points raised in the paper. At the commencement of his year of office, he referred to the matter of deposits; and he must again say that in the case of country companies, they were a source of much mischief and obstruction to any increase in the consumption of gas. The inhabitants in small towns had a very strong feeling against deposits. In one place he had heard of, where they were demanded of some publicans, they immediately resorted to oil-lamps. The deposit system was, he believed, being abolished in many cases, on account of its deleterious effect upon the consumption of gas. It was necessary that every obstacle which impeded the growth of the consumption of gas should be removed.

Mr. W. H. BROADBERRY (Tottenham) remarked that there was scarcely a point in Mr. Price's paper which at some time or another had not come under the notice of most of them; and he thought it would result in a considerable improvement to their business if they could remove the obstacles referred to. In the first place, the author mentioned the question of deposits. If (Mr. Broadberry) must say he felt very strongly on this question. There was no doubt whatever that there were not half-a-dozen

gentlemen present in the room who would not be considerably annoyed if the baker were to ask them for a deposit before he would deliver bread to them. Why gas companies should be different from other people in business, in the matter of demanding a deposit, he could not at all understand. A few years ago, he must admit, they were a little more independent on the subject of the supply of light than they were at the present time. They could then say to intending customers, "You must come to our terms, or we will not supply you with gas." But this was altered; and they had now to show more consideration to the consumers' terms. The general demand for deposits could not be justified under any system of business whatever. For some years he had to work against his conscience, and ask for a deposit from every consumer. Nine months ago, his Company were not supplying gas in their district to more than about 25 per cent. of the inhabitants; and he certainly believed the principal cause was the infliction of the deposit.

Mr. LIVESEY: In every case?

Mr. BROADBERRY replied in the affirmative. Their instructions were not to put on a supply of gas without a deposit; and only consumers who were in existence before this rule was laid down were exempt. He made several reports on the subject; and the system had now been abolished. What they did now was to ask the name of the company that last supplied the intending customer; or if they could show by their receipts that their gas accounts had been promptly paid and so on, then they were supplied. If not, the company wrote for a reference; and if they did not get a satisfactory one, they found the simplest plan was to ask for a deposit. He had one case not long ago, in which he wrote to the company who had previously supplied the person applying for gas; and the answer came back: "Kindly give us his address; he owes us for two quarters." (Laughter.) As to the question of oil, there was no possibility of doubt that gas companies had to consider this more than the electric light. He carried out some extensive experiments on this matter of oil lighting; and there was no doubt that, light for light, gas at 8s. per 1000 cubic feet could not compete with oil. When, however, the trouble, the cost of chimneys, &c., was taken into account, most people would gladly pay the small additional cost of gas. He advocated that gas accounts should be collected at shorter intervals than three months. Whether prepayment was to be the system of the future, or whether the collections were to be easier, he did not know; but he certainly thought they should make the collection at least monthly, or even at shorter periods than that. In regard to the question of fittings, the first cost was considerable for small householders. They could buy a good oil-lamp for 15s.; but if they wanted a supply of gas they must spend about £3 or £4 for fittings in order to get the same amount of light. They would have to endeavour to meet the small householders in this extraordinary expense; and then they would certainly be able to hold their own. He thought that the fittings should be put in by the gas companies, and a monthly rental charged for them. The prepayment meter Mr. Price had exhibited was a very ingenious contrivance, and would help to meet the difficulty of quarterly collections.

Mr. GEORGE LANE (Aylesbury) contended that deposits were, in certain cases, absolutely necessary. At Aylesbury, they found it essential to require them from the publicans, and allow teetotallers to go "scot free." They found, on looking back for some years, that the bad debts were mostly caused by the coming and going of the publicans, which showed, perhaps, that they had not a large and lucrative business in the town. In reference to the meter exhibited, it appeared to him to be like a money-box; and when a tenant happened to be in arrears and in serious difficulty, he (Mr. Lane) thought there would be the temptation to disconnect the meter and run off with the source of profit.

Mr. C. E. BOTLEY (Hastings) said it seemed to him that in discussions of this kind very great difficulty occurred on account of there being different kinds of procedure in regard to deposits and so forth in various towns. There were not two cases that seemed to be the same in every respect. By recent Gas Acts deposits were sanctioned, provided 5 per cent. interest was paid on them; and he could not conceive that there was any injustice in this. In his own case they asked for a reference from the company who previously supplied the person wishing to have gas; and if they had a satisfactory reply, they connected the meter. In other cases they demanded a deposit, and allowed 5 per cent. upon it. One of their customers a short time ago inquired if they wanted any more money, because he could let them have some at the same rate of interest. With regard to laying on the gas, they were very liberal to their customers, as they put in 100 feet of service-pipe free of charge; and if it extended farther than this, they let them have it at cost price. They did not charge anything for fixing the meter. They charged meter-rents, though he should like to do away with them; but his Directors thought the amount of revenue produced under this head would not justify their abolition.

Mr. LIVESEY: If you abolished meter-rents, you would have to put up the price of gas.

Mr. BOTLEY: Just so; and the consumers appreciated a reduction in price more than the abolition of meter-rental. As to complaints, all gas companies received them. The consumers used in a great many cases bad gas-fittings and bad burners; but they would not be convinced that these were the real cause of their complaints, and said that the gas was bad. The Hastings Town Council had recently appointed a Gas Examiner. They had had extremely good reports from him; and now he believed the Council thought they had made a mistake. They had appointed an

Examiner to test the gas; and he was giving the Company a good advertisement, by showing that they more than carried out all their legal requirements. As to the prepayment meter, there was no doubt that they would, if they wished to cultivate the small class of consumers, have to look to something of this kind to help them. The question of fixing fittings in small houses was, he thought, the more serious question for gas companies to consider.

Mr. C. GANDON, referring to the deposit question, said that if it was necessary to ask for a deposit at all, great discretion should be used. If they knew they had an untrustworthy person to deal with, of course a deposit would have to be demanded. He had found the same thing as had been mentioned by a previous speaker with regard to the losses by publicans. They were very difficult people to deal with. They went into a public house, and would leave before the gas officials were aware that anything was wrong with them; and then it would be found that the brewer had a lien on everything in the place. As to meter-rents, this was also a question on which it was rather difficult to lay down any absolute rule. The Crystal Palace District Gas Company made a charge of 9d. per quarter for meter hire; the object being not so much to obtain a profit, as to prevent people keeping meters in their houses when they did not use gas. If no charge was ever made, some people would allow the meter to remain *in situ* when they were not using gas, rather than have it removed. As to Mr. Price's prepayment meter, he had not yet had an opportunity of examining it; but he was rather disposed to think that the contrivance would be found difficult to work in practice. Could the meter discriminate between a half-crown and a piece of lead of the same weight as a half-crown?

Mr. JABEZ CHURCH (London) said that, with regard to gas-fittings, he thought it was a question that all gas managers would have to consider—how they could put proper and good fittings in houses. It was certainly one of the problems which gas managers had to solve. In the case of water companies, they had their own plumbers; and they had to use stipulated fittings.

Mr. C. C. CARPENTER (London) said he was afraid there was a tendency to run after the small consumers, and let the large ones go after the electric light. Electric light was no doubt making headway; and he thought that the subject should be dealt with. For himself, he believed that everything could be done with gas that the electric light was capable of effecting. He was one of few gas people who lived within the range of electric lighting. They were on one of the oldest circuits in London; and they were continually having breakdowns. With the electric light, unless they had some artificial means of ventilation, the atmosphere was not so fresh as with gas light. They heard people say that ferns and flowers were unable to live in rooms lighted by means of gas; but his ferns "turned up their toes" in a week in a room where the electric light was used. By putting in one of Sugg's ventilating burners, however, the difficulty was overcome. The other occupants of the house where he resided were quite ignorant as to what gas could do; their notion of it being based upon that relic of barbaric gas times—the union-jet burner—whereas gas lighting could be made as artistic and decorative as electricity itself, at less than one-third its cost. He thought the proper education of the consumer was a very important subject, and one that would have eventually to be taken up. He noticed nearly every night, when going home, that some shop or hotel or lodging-house had the electric light where it was not on the night before.

Mr. CUTLER urged the desirability of giving more attention to the small consumers than was done at present. In conjunction with Mr. Cloudesley, he had devised a meter to enable gas to be paid for beforehand; and he might say, it would be shortly brought before gas companies and corporations for their consideration.

The PRESIDENT considered the subject they had been discussing was a very interesting one. He thought that if the prepayment meter came into use, some arrangement should be made with the landlords of small houses to put in gas-fittings. In regard to the use of oil, he had read in the papers that the authorities in one part of China considered that more material damage had been done by the oil than by the opium traffic. He believed in Mr. Botley's plan of supplying the services and fixing meters free of charge.

Mr. PRICE, in reply, said that in reference to the question of fraud in connection with his prepayment meter, the arguments that applied to a machine for supplying sweets and so on would not apply to his instrument, because in the case of the meter there was a responsible owner; while with a machine at a railway station a person could drop in a piece of lead and be 100 miles away before the collector came round to take away the pence. As to the question of running away with the meter, he did not think anyone would do this for the sake of the few shillings contained in it; besides, a meter was not a thing that a person could remove without being seen. With this machine he should think the collection ought to be made once in six weeks. As stated by one gentleman, there was no doubt that the use of the electric light was increasing in the houses of the wealthy, and those to whom expense was no object when a new and attractive light was the temptation; but let things settle down to the inevitable balance of supply and demand, and the usual comparisons of expense—when the quarter's electric light bill was compared with the corresponding quarter's gas account—and he had no fear but that the "survival of the fittest" would obtain. He was strongly of opinion that the small consumers should be looked after; and he believed that a considerable amount of revenue could be obtained from them. He was much obliged for the attention that had been given to his paper.

AMERICAN GASLIGHT ASSOCIATION.

The Sixteenth Annual Meeting of this Association was held at Toronto—as already intimated in the JOURNAL—on the 17th, 18th, and 19th ult. The PRESIDENT (Mr. T. Turner, of the Charleston Gas-Works) occupied the chair. The summary of the proceedings which we publish to-day, and shall continue in subsequent issues of the JOURNAL, is prepared from the "Official Report" published in the *American Gaslight Journal*.

The first matter which received the attention of the members was the report of the Executive Committee, who recommended that a portion of the surplus funds of the Association should be disposed of in the purchase of badges, at a cost of about \$4 each, one of which should be presented to each member. The report having been accepted, the Secretary and Treasurer (Mr. C. J. R. Humphreys) read the financial statements.

The PRESIDENT then proceeded to deliver his Inaugural Address. He commenced by congratulating the members on the general and almost unprecedented prosperity that had attended the gas industry during the past year. The increase in the consumption of gas had ranged from 5 up to 30 per cent. Considering the cause of this, he thought the natural tendency with all consumers was towards the use of more light. The low price allowed a more free and extended use of gas; and the consumption for cooking and heating purposes was constantly increasing. The application and use of the electric light had almost compelled people to have more light of all kinds; and though the market price of gas stocks had at times suffered from the progress of this new system, the gas business as a whole had rather progressed. He regarded the idea of "fighting" the electric light as a mistaken policy; and urged that they should rather lend their energies to the development of the possibilities in their own business, which were greater than most people were aware of. All things considered, gas must still remain, as it had been in the past, as best adapted for universal illumination and heating. He was not entirely in favour of the policy of amalgamating the business of electric lighting with that of gas lighting, and did not think that any man could manage two different kinds of business as he could one. One or other must in some degree be neglected, and perhaps both. At the same time he acknowledged that in some cases, local circumstances and conditions might render it advantageous to consolidate the two interests; and wise managers would be governed by these circumstances rather than by any general rule. If the gas industry had prospered during the last 30 or 40 years, in the hands of men who, in many cases, had no special training or education for it, he was certain that still greater improvements might be expected in the future, now that the carbonization of coal and the treatment of the resultant gases were more thoroughly understood; and that it would receive a fresh impetus when the young men who were now coming up with specially trained minds and hands, bent their energies to the development of the science of manufacturing illuminating and heating gas. With regard to naphthalene, conditions of carbonization, and other points, much remained to be learnt; and the engineer who was to be the most successful in the future, was he who had taken advantage of a thoroughly technical education, coupled with actual practical ability and application. Under the present system of education, the students had no opportunity of acquiring that practical judgment which must needs accompany a technical education in order to place them in the best possible position as managers of any great industrial establishment; and this was one reason why the man who had learnt a trade, and worked with his own hands, was usually more successful than the one who had acquired a theoretical education, but had never enjoyed the advantage of any practical experience in the work.

The Executive Committee on the proposed amendment of the constitution of the Association then presented their report, which embodied a remodelled set of rules; and after some discussion it was adopted. It was subsequently decided that the next meeting of the Association should be held at Baltimore.

The reading of papers was next preceded with.

Mr. W. H. PEARSON, of Toronto, read the first paper, which consisted of a description of the latest forms of Herr Lux's gas-balance. As this was similar to that given at the recent meeting of The Gas Institute in London, it is unnecessary to give an abstract of the present paper.

Mr. J. SOMERVILLE, of Indianapolis, contributed a paper, entitled "Daily Experience and Observations of a Gas Manager." Alluding to the retort-house, he said that he preferred that it should be built on the stage principle, as the best and cheapest in the end, and leaving ample room for the erection of generator furnaces. He found it quite sufficient to brace the settings in the front and rear only, and arranged them so as to allow enough space and also plenty of time for the combustion of the furnace gases. In passing, he laid some stress on the importance of the element of time in all gas-works operations. There was no advantage in running the heats so high as to approach a white heat, as the gas produced under such circumstances was poor, and would readily deposit naphthalene. The spent charge should, on the removal of the retort-lid, present a bright red sparkling appearance without a trace of smoke; and the coke should be curled up at the sides, and come out easily when the rake was applied. He also found that the higher the heats, the greater the production of ammonia. [It may be here remarked that the author's experience in this respect does not agree with that of many English gas engineers, or with the experiments made by Mr. Lewis T. Wright.] Self-sealing lids, Mr. Somerville continued,

were only so in name, as after the first year or so they were unable to stand the wear and tear of the retort-house. The hot scrubber, in which all the heavy tar should be deposited, ought to be so hot that the hand could not be held on it—say, about 120°. The light oils and naphthas would flow on with the gas; and these should be taken out in a Pelouze and Audouin condenser. Some gas managers place the latter appliance first, where he put the hot scrubber; but he objected to such a course, as being likely to impoverish the gas, and also to allow a little tar to pass forward to the scrubber. He preferred weak liquor of 2° or 3° strength to clean water in the scrubber. Referring to gasholders, the author said that his observations led to the conclusion that, whenever trouble occurred, it was due to the weakness of the bottom curb. Let the bottom rollers get out of place, and the stability and safe working of the holder was destroyed. Much had been said against the sperm candle as a standard of light; but he found that, when burnt under proper conditions, and with due corrections, it did, for all practical purposes, fairly test the illuminating value of the gas. When the specific gravity rose without a corresponding increase of illuminating power, it was time to look to the exhaustor governor. Every meter ought to be examined, and repaired if needful, every five years. The result of one year's testing of consumers' meters at Indianapolis showed that, out of 209 meters, 116 were correct, 53 slow, and 40 fast. The average percentage of slowness was 8.6, and of fastness, 7.3. As to the supply of gas for cooking and heating, he had taken this into his own hands with great success; having now over 2000 stoves out, giving great satisfaction. He also collected accounts weekly if desired; and at present he had 600 consumers on these terms.

In the course of the subsequent discussion, Mr. King referred to the statement that "the safe working of the gasholder was entirely dependent on the strength of the bottom curb and rollers" as agreeing with the claims of Mr. Livesey, Mr. Gadd, and others in England. Mr. Clark said he could not agree with some points raised in the paper. He used self-sealing lids successfully; the only point necessary being to take care that they were carefully scraped. He preferred to have the exhaustor close to the hydraulic, as it then needed no lubrication; but he agreed that the hot scrubber should come immediately after, and before the Pelouze and Audouin condenser. Mr. Mooney, Mr. M'Millin, and Mr. Scriver spoke in favour of self-sealing lids, supporting the remark made by Mr. Clark on this subject. Mr. Scriver had followed with great advantage the advice given in the paper with regard to the use of gas for purposes other than lighting, to the extent of making his own stoves, and supplying them at cost price, and also offering a special rate for the gas so used. Mr. Harbison supported the reader of the paper, but did not agree with the policy of Mr. Scriver in charging a special price for gas used for purposes other than lighting. He believed in a uniform price, and this so low that everybody could afford to use the gas for every purpose. He had no hot scrubber, but used a Walker tar extractor and a standard washer; and this arrangement he found to answer well. Mr. Nettleton suggested that self-sealing lids would work well for small but not for large retorts. Mr. Floyd demurred to this; and thought that the principal difficulty lay in the treatment of the lids. Mr. Somerville, in the course of his reply, entered in detail into some of the reasons that had led him to the conclusions expressed in the paper.

The Committee on Standard Meter Unions reported that, after careful consideration, they had decided to recommend the adoption of the following sizes:—

Size.	Standard Thread.	Diameter.	Tail of Swivel.	Nose of Swivel.
		Inch.	Inch.	Inch.
3-light meter . .	18	.. $\frac{3}{16}$.. $\frac{1}{8}$.. $\frac{1}{8}$
5 " . .	12	.. $1\frac{1}{8}$.. $\frac{1}{4}$.. $\frac{1}{4}$
10 " . .	11½	.. $1\frac{3}{4}$.. $1\frac{1}{4}$.. 1

The Committee also recommended that the foregoing be submitted to other Associations for approval and adoption, and that they should continue their labours with regard to other sizes of meters, and report at the next meeting. It having been proposed and seconded that the report be accepted, Mr. Down, the Chairman of the Committee, entered into a full explanation of the course by which the Committee had been guided. They found that the meter-connections in use differed in diameter, in number of threads to the inch, and in the size and shape of the thread; and it had been their endeavour to arrive at a standard that would, as nearly as possible, be a mean between these differences. Even $\frac{1}{16}$ of an inch variation in diameter made a great practical difference, enough to bother anyone in attempting to make the coupling. It was the desire of the Committee (which comprised representatives of the principal American meter makers), if their recommendations were adopted, to make a set of steel standards at their own cost, and place the same in charge of the Association. Responding to a suggestion from Mr. A. C. Humphreys, he said he thought the standard unions might be made of a distinctive shape, or stamped with the letter "S." Being asked whether the new standards would fit all existing meters, he replied that they had been carefully selected to fit the greatest number; but it was useless to deny that some difficulty would arise, until the standards were generally introduced. After some further discussion, the report was adopted. On the motion of Mr. Harbison, it was decided that the three standard sizes embodied in the report should be adopted by the members of the Association on and after March 1 next, and that the Committee be requested to design other standard sizes.

Mr. F. MAYER, of Baltimore, then read a paper on the "Construction of Gasholders with Wrought-Iron or Steel Tanks above

Ground." He said it had been the desire of gas engineers in all modern works of magnitude to provide an easy access to all parts of the apparatus. The advantages of this system were apparent; and in works where all the apparatus was above ground, exposed to air and light, it was an easy matter to control and maintain the same in a proper state of repair. But little or no attention was paid in this direction as to the construction of gasholder tanks; the old and well-known brick tank being repeated in almost every instance, although it was known that the guarantees for perfect construction and proper results were doubtful, even in good ground. With a view of meeting this objection, he had proposed and advocated for three years the construction of wrought-iron or steel tanks built above ground, and had erected several on this principle, which appeared to him to yield the advantages of reduced cost of construction, less time required in construction, positive assurance of proper construction, easy accessibility to all parts, and no deterioration of the ground. The probable cost of a brick tank in treacherous ground was very uncertain; but the cost of a suitable foundation on which to construct an iron tank was comparatively easy of estimation. Even in tanks of 35 feet depth, the load per square foot would not exceed a ton, which was not an unusual pressure on foundations. Piling was necessary in very bad ground. The character of the soil could readily be determined if an iron tank was to be used; but proper tests for a brick construction were difficult of attainment, owing to the increased depth. Consequently, expenses for additional sheet piling, &c., and dealing with water and quicksand, were frequently incurred in excess of that originally contemplated. This extra expense was coupled with delay in completion. The time which would be occupied in construction could be established with certainty to within a week or two, when iron tanks above ground were used, and was 20 to 30 per cent. less as compared with ordinary brick tanks. With proper precautions in erection, the iron tank would be fairly reliable as to soundness; but brick tanks frequently did not develop their defects till they had been filled with water. The cause was simply that the exterior of the latter was inaccessible. Therefore defects might exist there that could not be observed from the interior, but which in the case of an iron tank would be at once seen and remedied. An iron tank could be readily taken apart, and removed to another site, if desired; leaving the ground free and undisturbed, ready for immediate use as a building site or for any desired purpose. Attention was then directed by the author to the details of construction, as exemplified by photographs of tanks erected on this system. The entire weight of the guide-framing, which was of wrought iron, was supported by the side plating of the tank. The bottom was perfectly horizontal, and solidly bedded upon the foundations with cement grouting, poured in through hand holes after the bottom was in position. The strains imposed upon the ironwork of the tank by internal pressure were directly proportional to the diameter, and in the construction shown did not in any part of the rivetted joints exceed 10,700 lbs. per square inch. The strength of the rivetting as compared with the plating was 81 per cent. for the lower vertical triple-rivetted seams, and 76 per cent. for the upper double-rivetted seams. The upper edge of the tank was formed of a strong continuous circular girder of plate iron; and the supports for the standards consisted of large brackets extending through the entire depth of the tank, constructed of angle and bar iron. The weight of the guide-framing was thus uniformly distributed over the whole surface of the foundation. Quite a "low" overflow was provided in addition to the ordinary one near the edge of the tank; so that the water could be lowered when necessary, to admit of painting the inner and upper surface of the tank at this point. In large tanks it was very necessary to make provision for expansion and contraction. The guide-framing consisted of trussed standards, joined by lattice girders, and diagonal tie-bars. It was light in appearance, but stronger than the usual pattern. As a proof, he cited a tank and holder 100 feet in diameter at Memphis, which was caught in a tornado just when inflated to its full height for testing. Though the wind reached a velocity of 70 miles per hour, the holder was not the least damaged. Combined systems of radial and tangential rollers were used; and the carriages were constructed entirely of wrought iron under recently obtained patents. An important question was how to prevent the formation of ice. Spare steam might be utilized if obtainable; but where additional apparatus was necessary, he preferred heating by hot water. In any case the heating surface should be uniformly distributed round the inner circumference of the tank.

The paper was discussed at some length. Mr. Harbison considered the plan described in the paper a vast step in advance of present experience. It would be a great advantage to him if all his tanks were as tight as he believed these iron or steel tanks could be made; and he thought that most of the members had had more or less experience with leaky tanks. He was located where there was a rise and fall of 27 feet in the water level; and the ground was made ground. Of four tanks, two had already been lined with $4\frac{1}{2}$ -inch brickwork, and a third was split from top to bottom; and he was considering the advisability of putting in an iron or steel lining instead of a brick one. In building a new tank, he should therefore be inclined to try Mr. Mayer's plan. As to the prevention of ice, it would not be a difficult matter to house the holder and tank together. Mr. Somerville thought there would be some difficulty from rust, particularly at the bottom of the tank, and also from freezing. Mr. A. C. Humphreys quite agreed with the reader of the paper.

He did not believe there would be any trouble from rust; but thought that extra precautions against frost would be necessary. Mr. Mayer observed that iron under water, or otherwise protected from the air, merely became covered with oxide and then stopped rusting; so he thought there would be no difficulty in preventing the formation of rust, as the outside was open to examination. The bottom plates ranged from $\frac{1}{4}$ to $\frac{3}{4}$ inch according to the size of the holder, and were about 4 feet wide by 16 feet long.

Mr. D. H. GEGGIE, of Quebec, read the next paper, which was entitled "Experience in Distributing Gas under Extremely Low Temperatures." He commenced by stating that at Quebec the winters are long and severe; the average temperature from Nov. 1 to April 1 averaging about 15° Fahr., and for at least two months of that time it was below zero. His gas was first passed through an air condenser, then a St. John and Rockwell scrubber-condenser, next a series of upright pipes provided with a lattice-work of corrugated plates, and lastly through a standard washer. This apparatus not only eliminated tar, but prevented trouble from naphthalene either on the works or elsewhere. The illuminating power of his gas, as tested by the Government Inspector, averaged nearly 18 candles throughout the winter. He used Newcastle and provincial coal, with 4 per cent. of cannel; and attributed the small percentage of enricher required to the efficient action of the St. John apparatus. The gasholders were all enclosed in buildings heated by steam; and the distributing plant was divided into three sections, each with its own governor, and subdivided by valves, so that in case of breakage or fire a small section could be shut off without interfering with the rest. The mains were 4 to 6 feet deep, laid near the curb line, and protected in damp or rocky ground with wood cases, tar, and sawdust. He found the lead joint preferable to the turned and bored joint, as more elastic and less liable to fracture by frost, contraction, or subsidence; and he now used lead joints entirely, as, if the frost reached the pipes, it was invariably the body of a turned and bored joint that broke. On account of the low temperature, the gas was reduced to the extent of 5 per cent. in volume in the course of distribution. The exposure of his mains and services in the course of laying water and drain pipes caused him much trouble; and as the earth was frozen when the trenches were re-filled, great difficulty occurred when the thaw came in the spring, when his mains would sag, fill with water, and break, owing to the subsidence of the ground. In the extremely cold weather, the services remained clear; but at warmer temperatures frost would form close to the walls of the house, and cut off the supply. This was removed by means of spirits.

In the course of the discussion, Mr. R. Baxter, who said he was also a native of the frigid zone, related some of his experiences. At Halifax the temperature did not fall quite so low as at Quebec; but while the latter town was peculiarly well adapted for districting, Halifax, like many other towns, was not. Although his pipes were 4 or 5 feet deep, the frost would sometimes get down to them; but he did not find the turned and bored joints break; and in fact used them entirely. His great difficulty, both with mains and services, was due to people making drains, &c., and not filling up the ground properly below them. He used wet meters, charged with one part of methylated spirit to two of water, which answered well, but caused some annoyance from evaporation. Glycerine was also employed; and each meter was fitted with a reserve supply of liquid. Mr. Scriver, of Montreal, said he also came from a cold country; and his great trouble was excessive capital. Having to house in all the plant, and also to keep it warm, and to lay the mains 5 feet deep, the cost of plant was increased to about double of that which would be sufficient in warmer climates. On more than one occasion, he had lengths of 100 feet of main or so frozen solid; and the only remedy was to open the ground and build coke fires upon the pipes. He was also much troubled with naphthalene; and this principally when the winter set in. Another disadvantage he had to encounter was that, not having railroad communication with the mines, he was under the necessity of laying in a very large stock of coals in the summer season. He did not lay pipes across bridges, but went down underground instead. Mr. Shelton, of Philadelphia, remarked that he had used slacked lime to thaw frozen ground instead of coke. He took off a few inches of earth, spread the lime in the space, poured water on, and covered it over closely with canvas. By the next morning, the frost had been drawn out of the ground to a depth of nearly 3 feet. The lime required to be left for a night to give it time to work. Mr. A. C. Humphreys remarked that the difficulty with frozen mains, &c., arose where the line of frost and the line of pipe intersected. If laid at various levels below the surface, the pipes would be exposed to the frost in some parts, but would be found below it in others. Mr. Starr, of Richmond, Ind., said he frequently had the temperature 20° to 25° below zero, and was much troubled with his lamp columns, until he put in $1\frac{1}{2}$ -inch services, instead of $\frac{3}{4}$ -inch. With regard to frozen holders, he had put small iron brackets round the inner edge of the tank, to support a frame of wood, which, as nearly as possible, covered the exposed surface of the water. Throughout the cold season, a layer of manure was put on the frame; and this prevented any trouble. He carried up the tank wall about 3 feet above the water-level; and this plan was no doubt some help. At bridges and exposed places he had enclosed the mains in wooden boxes. Mr. Pearson, of Toronto, observed that he had followed the same plan, and found his experience agree with the suggestion made by Mr. Humphreys. He was much troubled with frozen service-pipes; and he found methylated spirits effective for thawing them out. Mr. Lindsley,

of Cleveland, said he had efficiently protected a service-pipe in a very exposed situation, by providing a wooden box one inch larger than the pipe, and filling in the space with pitch. Mr. A. C. Humphreys, in reply to enquiries, said that he always widened the pipe at all exposed parts. On a line of 8-inch pipes for instance, where crossing a bridge, he would lay 12-inch pipes. If they were covered with canvas, so much the better; but he did not think the pipe would freeze without covering. He had applied this plan to lamp posts with great success; using 1½-inch pipes in place of ¾-inch. He did not consider that the expansion merely left room for the frost, but that a less actual formation took place in the larger pipe. Mr. Douglas, of Savannah, also testified to the success of this plan. Mr. M. Millin, of Columbus, had two lines of 16-inch pipe crossing a bridge, which caused much trouble. At the point where the gas entered the exposed part, the main was carried perpendicularly out of the ground to a height of 5 feet or 6 feet. He enclosed this part in an 18-inch pipe, packing the space with felt, and for 10 feet or so beyond added a jacket of sheet iron with the object of causing the exposure to cold to be gradual, and not sudden. He believed that the application of this plan would prevent trouble in all cases. Mr. Slater, of Providence, preferred cement joints to lead joints for mains; and said he did not find the rigid joints broke at all. If he hated anything it was broken pipes. He always boxed in the pipes passing over bridges. This concluded the first day's proceedings.

DEATH OF MR. D. VINCENT, OF ERITH.—The death is announced of Mr. Daniel Vincent, who for 28 years had been Manager of the West Kent Gas Company's works at Erith. He was 63 years of age, and had charge of the works before the West Kent Company was formed. He enjoyed the entire confidence of the Directors from the time of his taking service under them, on the formation of the Company in 1865, until the last. He proved himself to be a thoroughly practical man of business, and remarkably well fitted for the discharge of the duties with which he was entrusted. The late Mr. Vincent's father (Mr. Matthew Vincent) was Manager of the Crayford works.

MID-SUSSEX WATER COMPANY, LIMITED.—The prospectus of this Company, which has been formed for the construction of works and the supply of water to Hayward's Heath and other places in Sussex, has been issued. The capital is £35,000, in £5 shares; and the Company have borrowing powers to the extent of £8750. It is proposed to issue 6000 shares at par; but only three-fifths of the amount will have to be paid within three months from the date of allotment. The population of the district covered by the Company's powers is estimated at about 14,000, who are at present in urgent need of a good supply of water; the existing sources being much contaminated. The works have been designed by Mr. Jabez Church, M. Inst. C.E., F.G.S., and are being carried out by Messrs. J. and H. Robus.

OVERHEAD WIRES FOR ELECTRIC LIGHTING.—In the House of Commons last Thursday, Mr. Bradlaugh asked the President of the Board of Trade whether the Board had sanctioned any existing overhead wires for the purpose of electric lighting; and whether they intended to authorize, under Provisional Orders or Licences, the transmission of electricity at high tension by such wires within the Metropolis. Sir M. Hicks-Beach replied that no overhead wires had been sanctioned so far; and although he was not prepared to make any definite promise as to future applications on the subject, he should not be disposed to accede to such request. In reply to a question by another member, as to whether or not he had power to prohibit the erection of overhead wires, he said he would rather not give an answer at present.

A HANDBOOK FOR THE LONDON COUNTY COUNCILLORS.—Mr. D. Nutt has published a neat little work by Mr. G. Laurence Gomme, F.S.A., upon the duties and powers of the London County Council under the Local Government Act of the current year. Mr. Gomme has written an interesting introduction to his subject, in which he recognizes that the method adopted for dealing with "such a concentrated area of human life as London," by invoking the idea of the shire or county, was a stroke of good statesmanship. It is regrettable, however, that writers of books who take the trouble to prepare introductions or prefaces to explain the objects of their works, so frequently fall into a slipshod way of expressing themselves in these explanatory compositions. In this instance, it is to be presumed that Mr. Gomme knows what he means by such a contradiction in terms as "a concentrated area;" but the phrase certainly looks odd. Concentrated soup we know, and to concentrated attention we are not strangers; but how an "area" is to be concentrated surpasses our ken. This, however, by the way. Mr. Gomme has presumably been more careful of his facts than of his language. There is an ample index of subject titles; and the contents of the book are arranged alphabetically in short paragraphs, under side-headed titles printed in bold capitals. Every subject respecting which inquiry may be made is consequently easily found, and the required information ascertained at a glance. The incorporated Acts are in most cases referred to, together with other information to the point. Thus, under the heading "Gas Testing," there are references to the Acts under which the duty of testing gas was confided to the Metropolitan Board, and also a list of the testing stations. The book will be found a concise index to the Local Government Act itself, and the other statutes which have to be construed with it. It is clearly printed, and well worth the small price asked for it.

NEW PROCESS FOR THE TREATMENT OF AMMONIACAL LIQUOR.

In the number of *Industries* for the 9th inst., an illustrated description was given of the plant in use at the Wear Patent Fuel Works, Sunderland, for the treatment of ammoniacal liquor for the manufacture of sulphate of ammonia. Since the first adoption of apparatus for this purpose, various minor improvements have been made in its arrangement; the latest—a new method of dealing with the waste gases—having been introduced at the beginning of March last. The General Manager of the works (Mr. W. Dixon) courteously furnished to our contemporary drawings of the plant and a description of the entire process; and from these the following particulars, with the accompanying illustrations, have been prepared.

FIG. 1.

FIG. 2.

As stated above, the new arrangement was brought into use at the beginning of March last. Prior to that date, the "column" system was employed at the works; and the plant is still retained, being made use of when that for the improved process is being repaired. The annexed illustrations show in fig. 1 an elevation, and in fig. 2 a plan of the complete plant. The first process through which the liquor passes is that of being boiled. This is effected in the "stripper," an egg-ended cylindrical boiler A, 25 feet long and 6 feet in diameter, elevated above the ground, to allow the necessary connections of pipes to be made for carrying off the sedimental refuse to the drains. The boiling is effected by means of steam, at a pressure of 60 lbs. per square inch, which is passed into the stripper through a system of 2-inch copper pipes from the main boilers. The portions of the pipes inside the stripper are perforated, so that the steam comes into actual contact and mixes with the liquor. As soon as the latter has been raised to boiling point, the supply of steam through the perforated tubes is cut off, and the boiling is continued by means of steam passing through a coil of pipes which is also located inside the stripper. The vapours from the liquor, which commence to evolve at a temperature of about 190° Fahr., pass out of the stripper through metal pipes B to the saturators C, situated in an adjoining building, where it is neutralized in the ordinary manner by means of sulphuric acid. As soon as the process of neutralization is completed, the fluid is passed into the settlers D or D', situated conveniently below the saturators—settlers D and D' being in connection with the saturator C; while the remaining settlers E and E' and the saturator C' form an independent arrangement in connection with the column F. In case of need, however, both sets of saturators and settlers can be used for either the old or the improved process. After the settling process is completed, which usually takes about an hour the clear liquor is passed into the evaporators G and G', which are of the ordinary type, having in close conjunction drainers H, on which the sulphate is deposited. Returning to the stripping process, the lime is introduced into the boiling liquor, as in the ordinary column process, in order to free the fixed ammonia; and one of the advantages of this improved method is that it facilitates the lining process, which is effected by injecting the lime by water pressure into the top of the stripper. Besides other minor advantages as compared with the column system, Mr. Dixon's improved arrangement obviates the necessity of heating the liquor prior to

introducing it into the stripper. There is also a considerable saving of time, as the entire operation of treating 3000 gallons of liquor is effected in the new plant in from 8 to 18 hours, according to the strength of the liquor; while in the old system from 10 to 20 hours were occupied in completing the process.

The disposal of the waste gases is also carried out by an improved method. The sulphuretted hydrogen which accumulates in the saturators passes through suitable pipes I to the condensers J and K. Previously these gases were discharged underneath the grates of the furnaces of the main boilers. This practice, however, had to be abandoned under the provisions of the Alkali Act. The gases are now conducted into the condensers J and K, which are two flat-ended cylinders 12 feet high and 3 feet in diameter. They are connected together by a cast-iron pipe L, 8 inches in diameter, and placed at an angle so as to connect the bottom of the condenser K to the top of the condenser J, as shown in fig. 1. The gases enter J, and are therein partially condensed by the atmosphere and by a spray of water. After passing through the condenser K, all the moisture in the gases is removed. They then pass through a 6-inch pipe into one of the two purifiers M and N. Each of the condensers is provided with traps formed of 2-inch pipes for passing to the sewers the retained moisture and the water used in condensing. The purifiers shown are built of bricks, and are 7 feet square and 6 feet deep. Some distance above them is erected a substantial shed roof O to protect from the weather the oxide of iron with which the purifiers are filled. As already indicated, the gases from the condensers pass into the bottom of one of the purifiers, although two are provided, so that in case one becomes fully charged, the other is available while the sulphuretted oxide of iron is removed and the purifier recharged.

ISSUE OF ADDITIONAL DEBENTURE STOCK BY THE SOUTHWARK AND VAUXHALL WATER-WORKS COMPANY.—The Directors of the above-named Company are about to offer for sale, by tender, £100,000 of 4 per cent. perpetual debenture stock; being a portion of the additional capital authorized by the Company's Act of 1886, and created by the resolution passed by the proprietors at their meeting on the 30th ult. The stock will be consolidated with the existing 4 per cent. debenture stock, and will rank before the present paid-up stock and share capital of the Company.

DEATH OF MR. J. LEIGH, OF MANCHESTER.—We regret to announce the death, on the 11th inst., in his 74th year, of Mr. John Leigh, M.R.C.S., Medical Officer of Health for the City of Manchester, and Gas Analyst to the Gas Department of the Corporation. In the latter capacity he was some years ago engaged in making experiments, and became convinced that the illuminating power of gas did not lie in the olefant gas, to which it had usually been attributed, but to more condensed hydrocarbon or hydrocarbons. To test this he passed a quantity of gas through fuming nitric acid, and obtained a large quantity of nitro-benzol and oxalic acid. The discovery of nitro-benzol had been made long before by Mr. Leigh, and was communicated by him to the British Association at their Manchester meeting in 1842. The deceased gentleman was interested in other departments of science, and also possessed considerable literary ability.

SOCIETY OF ARTS.—The first meeting of the 135th session of this Society will be held to-morrow evening, when the opening address will be delivered by the Duke of Abercorn, C.B., Chairman of the Council. We mentioned last week that arrangements have been made for Mr. W. J. Dibdin, F.I.C., F.C.S., to read a paper on "Standards of Light," on the 19th prox. Among the Cantor Lectures to be delivered on Monday evenings during the session, there will be four on "Light and Colour," by Captain W. de W. Abney, C.B., F.R.S.; four on "Instruments for the Measurement of Heat," by Mr. C. V. Boys, F.R.S.; and four on "Heat Engines other than Steam," by Mr. H. Graham Harris, M. Inst. C.E. Captain Abney's lectures will be commenced on the 26th inst.; those by Mr. Boys on the 25th of March next; and Mr. Harris's on May 6. The papers to be read after Christmas comprise one on the "Forth Bridge," by Mr. B. Baker, M. Inst. C.E.; and others on "Automatic Selling Machines" and "Secondary Batteries," by Mr. J. G. Lorrain and Mr. W. H. Preece, F.R.S., respectively.

THE LAYING OF GAS AND WATER MAINS IN THE METROPOLIS.—With the view of placing the London County Council, when elected, in a position to proceed with the measure, the Metropolitan Board of Works have given notice of a Bill to amend the local management of the Metropolis, one of the clauses of which is to confer upon the Council and upon the Vestries and District Boards named in Schedule B to the Metropolis Management Act, 1855, further powers to control and regulate the laying within their districts of mains and pipes for water or gas, or hydraulic power purposes, and to remove or limit the liability of such Vestries and District Boards for damage or injury to such mains and pipes; and another to confer on the Council, Boards, and Vestries further powers with reference to the formation of streets and roads, and to prevent or regulate the removal of gravel or other subsoil in the formation thereof, and the substitution of other material for such subsoil. They have also, with the same object, given notice of a Bill in reference to Metropolitan improvements, in which power is sought to prohibit the breaking up or interference with any new streets to be made, or the approaches thereto, for laying down any gas, water, or other mains or pipes, except with the consent of the County Council, and subject to such terms and conditions as to payment and otherwise, as the Council may determine.

Register of Patents.

GAS FIRES AND STOVES.—Rhodes, S. G., of Leeds. No. 15,529; Nov. 14, 1887. [6d.]

These improvements consist in applying to gas-fires or gas-stoves one or more tubes or diaphragms H, made of two corrugated plates of metal joined together at the sides, but open at the top and bottom, having a number of tubes A passing through them. The hot products of combustion pass on to the diaphragm through the tubes to the back, before

being allowed to escape to the chimney C. The tube is open to the atmosphere at the bottom, its upper end entering the box K; thus allowing a current of air to pass through H and out at openings E warmed. B is the burner for supplying the fire; and F, the fire-clay back of the stove. The arrows show the direction taken by the hot gases into the box or casing G, in which is placed a tube or diaphragm H. D is an opening for fresh air to pass through the diaphragm into the box K and out at E. I are the corrugations of the diaphragm.

SUPPLYING A DEFINITE QUANTITY OF GAS ON PREPAYMENT BY THE INSERTION OF A COIN IN THE METER.—Price, W. E., of Hampton Wick. No. 15,410; Nov. 11, 1887. [1s. 1d.]

In allusion to his invention, the patentee remarks that it has been found that the use of gas among the artisan classes and other small householders is checked by the present arrangements of quarterly payments (for which their weekly wages and general habits in relation to money matters do not offer facilities), whereas the collection of weekly gas bills would be expensive, and might necessitate the charging of a higher rate for such consumers. His invention therefore has for its object the removal of these hindrances to the spread of the use of gas, by providing a meter with fittings in addition to those usually appertaining to it, by which, on a coin of definite denomination being dropped into a slot provided for the purpose, apparatus connected with the recording mechanism of the meter is operated, so that the consumer may obtain a definite supply of gas.

Fig. 1 [see next page] is a plan, and fig. 2 a sectional elevation of parts additional to an ordinary meter, together with the ordinary recording wheels forming the apparatus when the shaft is placed horizontally. Fig. 3 is an outside front elevation of the meter.

A is a horizontal shaft or spindle carrying the pointer *e* of the upper dial, the wheel *d*, the table B, and terminating in a stem on which a tubular spindle *a* connected with the valve C is made to slide. The counting-wheels of the meter are connected to, and are driven by the ordinary moving parts in the usual manner; and these give motion to the spindle *g*, and the wheel *h*, by which it is transmitted to the wheel *d* and the shaft A put in motion. Each revolution of the wheel is made to correspond with the passage of one unit quantity of gas—say, for example, 300 feet valued at 1s. D is a slide, which may be drawn out by the knob *i* for the purpose of inserting a coin. There is a slot quite through the slide for the reception of the coin, as well as a stud which fixes the distance to which the slide can be drawn out, so as to limit the size of the coin that can be inserted. Under the slide D, but separated from it by a horizontal partition (in which is a slot through which the coin passes, first partly and afterwards entirely), is a drawer K, into which the coins drop when they have passed the apparatus. Two chambers *s s*¹ are formed in a corner of the meter case, one above the other, separated by a horizontal partition *s*² communicating with the pipe G—*s* above and *s*¹ below the diaphragm *r*—and serving to conduct the gas from the pipe G to the valve C, and back again to the pipe G. When a coin *z* is inserted in the slot, and the slide D pushed home, the coin is carried against the arm or tail-piece *m*, which it pushes backwards, and is itself pressed downwards by the obliquely cut ending of the slot, until it assumes the position shown in the figure, where it is returned by the pressure of the tail-piece holding it against the end of the slot in the partition until it is released. When the tail-piece is pushed back by the coin, the arm *n*, which moves with it, is brought downwards so as to engage with the notch *n*¹; thereby preventing the slide being drawn out as long as the coin remains in the position indicated. The arms *m* and *n* are attached to the spindle E, which passes through a stuffing-box F, and carries the arms *o* and *p*—the latter of which carries at its end a pin-like projection; while the arm *o* terminates in a fork holding the tubular spindle *a* by the collar *a*¹. The disc forming the table B has a hole through it, into which the pin drops when the gas which has been paid for is consumed. This disc may be bevelled towards one side of the hole so that the pin may at first sink gradually; and thus, by partially closing the valve, give notice to the consumer that the supply is near

exhausted. When the hole *b* passes in front of the pin, the latter (being pressed forward by a coiled spring *q*) passes through, allowing the lever *p* to advance by the length of the pin, carrying with it the arm *o*, and thus moving the spindle *a* longitudinally, and closing the valve *C* and shutting off the gas. On an appropriate coin, however, being inserted in the slot in the slide *D*, and the slide pushed home, the arms *m* and *n* are operated as before, and the gas readmitted.

The meter thus started, the passage of the gas as it is consumed causes the rotation of the disc *B*; and the inclined surface of the projection or cam *c* soon comes in contact with the pin, and pushes it back further than it was carried by the pressure of the coin in the first instance, and thereby removing the arm *m* from contact with the coin, which then drops through the slot in the partition into the drawer. As the disc revolves, the cam passes from under the pin; and the pin

advances so as to be in contact with the surface of the disc. The other arms moving similarly, the arm *n* is raised out of the notch *n'*, leaving the slide free to be drawn out, and the arm *m* in position to be operated by the next inserted coin. If now another coin is inserted, the arm *p* is thereby moved back just far enough to lift the pin off the surface of the disc; so that, when the hole passes in front of it, the pin remains held back by the coin, but when the cam *c* passes the pin it again pushes it back, and releases the coin as before. The gas enters the meter by the inlet-pipe *G*, which is closed by a diaphragm shown in fig. 3 by a dotted line, and passes, by an opening in the side of the tube, into chamber *s*, and thence into and through the valve *C*, thence through the valve-box *C'* to the chamber *s'*, and so into the pipe *G*, below the diaphragm *r*, as indicated by the arrows, and thence into, through, and out of the meter proper in the usual manner. *H* is the ordinary dial of the meter.

THE CONTINUOUS PRODUCTION OF GAS.—Dempster, J., of Manchester. No. 16,582; Dec. 2, 1887. [1s. 3d.]

In his specification of this invention—which is described as relating “more particularly to the retorts and attachments used in the manufacture of illuminating gas from coal as is well understood”—the patentee remarks that the charging and drawing of retorts, if done by hand, is “laborious and uncertain, while most of the machines at present in use for these purposes are expensive in prime cost, difficult to keep in order, and occupy considerable space.” He has therefore devised an apparatus which is “easily worked, occupies little room, and

pushed into gear with the other half, whereby this latter half, together with the eccentric *e*, is caused to make one revolution; the loop *Z* in the cam groove being calculated to give exactly this length of contact between the halves of the clutch. The eccentric straps carry a tail *f*, which is formed as a rack, and which gears with pinions *g*, which are of such proportions that the rise and fall of the rack will cause the ram shafts to revolve sufficiently to give the proper charging advance to the rams, and also effect their withdrawal. To hold the tail rack *f* in gear with the pinions *g*, a bridle *h* and bowl are used. The space of time during which the bowl travels in the concentric portion of the eccentric

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

is considerably cheaper than existing machines; while the retorts may be charged and the coke removed either continuously or intermittently, as desired.”

In the illustration, the apparatus is shown applied to a set of six retorts *A B C D E F*, arranged in vertical sets of three and side by side; but it is, of course, understood that the apparatus is capable of application to single retorts or to sets of any number or disposition of retorts. In front of each retort is a mouthpiece *G*, which contains a reciprocating ram, by which the coal is thrust into the retort. Above the retort is a hopper *L* closed at the top by a door, which can be slid to and fro by a hand-wheel shaft and pinion *N*; the pinion gearing with a rack on the door. The coal in the hopper is led by branches *R* to the front of the retorts and rams. When the ram *H* is advanced, the plate with which it is fitted pushes the coal in front of it into the retort; and when it is withdrawn, a fresh supply of coal falls down from the hopper, and lodges in front of the ram ready to be pushed in by its next advance. When the charge of coal is beyond the reach of the ram-plate, it has been sufficiently long subjected to heat to cohere and form a caked mass, which will not break up before the pressure of the ram. The coal occupying the length of the retort is also sufficiently caked together by the heat to form a mass which will not break or crumble up, and which is pushed gradually through the retort by the successive movements of the ram. Some classes of coal cohere more firmly than others; and the length of the retorts has thus to be regulated in accordance with the behaviour of the coal employed. The retorts may either be arranged horizontally as shown, or set at an angle (sloping downward from the front towards the back) so as to assist the passage of the charge, and render it less liable to break up under the pressure of the rams.

The mechanism for automatically advancing and retracing the rams is as follows: Above the retorts and in front of the setting is a revolving-shaft *S*, carried in bearings *T*, and driven by a pulley and strap *V* from a small motor *U*. For each of the operating appliances there is on the shaft a worm *W*, which gears with a worm-wheel *X*, running loosely on a stud *Y*. In the worm-wheel is a cam groove *Z*; and a jawed and weighted bracket *a* hangs from the stud, and has an arm *b* to which is pivoted the link *c*. At the upper end of the link is a bowl, which runs in the cam groove *Z*. Midway between the arm *b* and the bowl, the link is connected to a clutch, one-half of which slides on the shaft *S* and revolves therewith by means of a slip feather and groove; the other half being loose on the shaft, and carrying an eccentric *e*. When the loop *Z* in the cam groove comes round and pushes the bowl and link *c* to one side, the sliding and revolving half of the clutch is

groove *Z* represents the dwell which takes place before the ram is again advanced and withdrawn.

The coal which has been fed into, and traversed through, the retorts in this manner falls in the form of coke from the delivery ends into the coke-delivery trunk *i*, which is simply a large upright box, into which all the retorts open, and which is provided with man or spy hole doors *j* opposite to the several retorts. The gas as evolved may be withdrawn in the ordinary manner or through an outlet *k* at the top of the trunk. At the foot of the trunk is a hinged door *l*, through which the spent charge of coke is discharged. It consists of a plate applied preferably at an angle to the mouthpiece casting; the casting and the plate being both machined or faced, so as to make a good joint when the door is closed. The door is held against the mouthpiece by a counter-balance weighted lever *n* held by a hasp. When the trunk *i* contains sufficient coke, the hasp is knocked aside, and the door is allowed to fall open, and permit of the coke being discharged upon the ground or into a truck or other receptacle.

CONTROLLING AND REGULATING THE DISCHARGE OF WATER OR OTHER LIQUID AT ANY HEAD BELOW THE INITIAL PRESSURE.—Braithwaite

C. L. and I., of Kendal. No. 13,649; Oct. 8, 1887. [8d.]

The objects of this invention are to produce an apparatus which will reduce to any desired extent the pressure of liquids passing into it, and also to provide means of admitting a liquid under pressure behind a diaphragm in any valves or cocks in which a diaphragm is used in connection with the controlling and regulating of liquids. To accomplish these objects, a diaphragm-valve is employed, past which the liquid flows; and that which has passed this valve is allowed to act upon a second diaphragm, connected by a lever with a small controlling-valve belonging to the diaphragm-valve in such a way that the pressure on the second diaphragm tends to close the controlling-valve.

GOVERNING THE SPEED OF GAS-ENGINES.—Wallwork, R., of Manchester, and Sturgeon, T., of Ilkley. No. 17,353; Dec. 17, 1887. [8d.]

In order to carry out this invention, there is fixed upon the slide-valve or some other convenient reciprocating part of the gas-engine a pin which works against an inclined lever in such a manner as to cause a constant up-and-down or to-and-fro motion of the lever. Upon the fulcrum of this lever is fixed another short lever having a projecting lip, which is called the “pecker.” This pecker is placed opposite to the end of the gas-valve spindle; but there is a certain space allowed between the end of the valve spindle and the pecker. This space is occupied by

a block on the end of a rod; and when the block is in its normal position and the pecker is depressed, it forces the block against the valve spindle, and so opens the gas-valve, and allows gas to be admitted to the engine, but when it is moved away the action of the pecker does not affect the gas-valve, which therefore remains shut—no gas being allowed to pass to the engine. The other end of the rod which carries the block is attached to a short lever carried by the same fulcrum, which carries another lever acted upon by a cam on the crank-shaft, so arranged that it will gradually raise the lever and suddenly release it. The raising of the lever pushes the block from underneath the pecker; and on the lever being released, it falls and brings the block again underneath the pecker. Should the engine be running at its proper speed, this block will return to its normal position in time to be caught by the pecker as it comes down; and gas will thus be admitted for the next stroke of the engine. But should the engine be running too fast, the block will not return in time to be caught by the pecker as it descends. Thus no gas will be admitted to the engine, which therefore slows down again to its proper speed.

MANUFACTURING ILLUMINATING AND FUEL GAS.—Rew, H. C., of Chicago, U.S.A. No. 12,733; Sept. 4, 1888. [1s. 1d.]

This invention embraces improvements upon matters described in patents granted in the United States. One of these, dated December, 1883, related to the continuous generation and fixing of gas; oil vapours being introduced into the fixing chamber to enrich the gas; superheating and fixing chambers being heated simultaneously by the combustion of gas free from ash; and nitrogen being excluded from the final product. A second patent, dated April, 1886, related to a method of heating superheating and fixing chambers simultaneously by passing downwardly through them the hot products of combustion from two hard coal furnaces connected at the base; the heat of the latter being maintained by conducting away the manufactured gas at the base in a similar manner. The superheating and fixing chambers containing refractory material extended from the bottom of the apparatus about its full height; means being provided for introducing oil into the chambers (the use of external metallic flues for the passage of the products or gases to the chambers being avoided). The third patent, dated April, 1886, related to the decomposition of superheated steam in the presence of gas in a chamber containing heated refractory material; the use of oil vapours to convert the carbonic acid thus produced to carbonic oxide; and the enriching of the final product. The fuel in the chambers located above the chambers containing the refractory material was heated by radiation and direct upward circulation of the gases used in heating the latter chambers, and by conduction through open flues in the masonry, so as to save heat that would otherwise be radiated upward into the open air and lost. The fourth patent, dated May, 1886, related to a method of heating both steam superheating and fixing gas chambers simultaneously, by passing hot products of combustion, generated in two hard coal furnaces connected at the top, downwardly through them; the heat of the latter being maintained, as in the previous patent, by conducting away the manufactured gas at the base in a similar manner. The superheating and fixing chambers in this case were located immediately below the fuel chambers.

The object of the present invention, however, is to provide much quicker and more efficient means for completely utilizing bituminous coal in the manufacture of illuminating and fuel gas by methods and apparatus which, though they have a general resemblance to previous plant, are nevertheless new. The operation is such that hydrocarbon vapours and gases are quickly expelled from bituminous coal; and the coal is first reduced to coke without the use of externally heated retorts, and without the passage therethrough of the heated products of combustion. Means are provided for conducting the hot hydrocarbon vapours and gases from the vertical retorts or compartments, adapted for coking coal, into the current of hot gases generated by the decomposition of steam, air, or gas in and by the hot coke which is first rendered incandescent by air blasts. The coke is supplied by gravity from the coking compartments to the chambers adapted for the decomposition of superheated steam. The coal is thus quickly coked; and the coke can then be converted into water gas in one continuous operation. The latter can then be enriched by the coal gas passing from the coking chambers without carbonizing the hydrocarbon vapours, and without suspending the operation to introduce either coal or coke. The heat radiated and conducted directly from the generating compartments and regenerators to the coal in the coking chambers is utilized to quickly expel the volatile and gaseous hydrocarbons from the bituminous coal employed; thus avoiding the use of costly and poor heat-conducting retorts and converting the coke into water gas without withdrawing it from the apparatus.

GASHOLDER CONSTRUCTION.

SIR,—Permit me to echo the hope expressed by Mr. George Livesey in his paper on this subject, in your issue of the 13th inst., that your contributor "Theory and Practice" will give us in pamphlet form the series of papers on gasholder construction which have appeared in your pages from time to time, and which I venture to think are the most valuable contributions of the kind which have appeared anywhere. The examination as to the stresses of every kind to which holders are liable under all circumstances, and the demonstration of the actual functions discharged by the various portions of the guide-framing, are far beyond anything I have yet read on the subject.

On a former occasion, I expressed the conviction that it would not be possible to reduce the height of the standards outside the gasholder, or to lighten their framing, without putting more than the saving in money into the floating part of the holder, in the shape of internal framing to stiffen it. All that has been written since—including Mr. Newbigging's eulogium of Mr. Gadd's invention, and Mr. Livesey's suggestions of curvilinear roller paths with tangential rollers—only confirms me in this belief.

If we are to have standards outside the holder at all, the higher they are carried the more effect will be given to the ties at the head of them in relation to the stress thrown by the gasholder; and they can only be cut down by being largely strengthened. Unless the guides project above the holder, Mr. Paddon's valuable plan of triangulated horizontal ties cannot be applied; and these are of the highest value in contributing stability. The illustration at the old works of the Surrey Consumers Gas Company only shows that the existing columns were far above the duty they had previously to perform.

Referring to the suggestions of Mr. Gadd and Mr. Livesey, there can be no doubt that in the model they will work fairly enough. There is equally no doubt that in gasholders of the size which are now commonly adopted, sufficient rigidity at the points of attachment of the numerous rollers on the curb, and sufficient accuracy in the adjustment of the roller paths (whether spiral or curvilinear), would not practically be attained without enormous cost and great weight in the floating part of the structure. The whole question is one of rigidity in the thing to be guided; and these are, as I have before observed, already getting to a weight which is inconvenient in practical operation.

I would point out the extreme liability of both these latter suggestions to jamming when the holder is flattened by side wind pressure; and to their exposing the holder to much friction and jerking when being rapidly raised or lowered. A further great practical drawback would be that the rollers would be inaccessible—being always submerged, and often at a depth rendering them entirely unapproachable in case of accident or requirement of adjustment.

Gas-Works, Stepney, Nov. 17, 1888.

HY. E. JONES.

COALS AND COAL CONTRACTS.

SIR,—I have no desire to obtrude into, or to prolong the discussion which is going on as to what are called gas scandals, coal purchases, substitutions, &c., &c.; but I think it most important that a reply from the highest authority should be given to questions which I venture to submit for insertion in your columns, viz.—

1. Is there any "trade mark" in the case of coal?
2. Is the same coal often sold under different names?
3. Are not some names which used to be distinctive of certain coals from particular pits now frequently applied to coal from other pits?
4. If coal is tendered at a price; if the coal is tested or guaranteed to produce certain results; and if price, test, or guarantee are satisfactory—what does it matter by what name the coal is called?
5. If when a contract is entered into, and deliveries are made in strict accordance therewith (without any substitution), where is there any wrong or fraud by whatever name the coal may or may not be called?
6. Is every truck of coal, every lump of coal, absolutely free from inferior matter; and, if not, is it fair to pick out portions of the inferior stuff only as samples of the bulk?
7. Is it not quite true that each coal contractor in his own estimation can supply cheaper and better material than any or all other coal proprietors? And does not this explain the secret of much of the present controversy?

It will be seen that the above questions have no reference to "commissions;" but I submit that they have an important bearing on the present controversy.

Nov. 15, 1888.

ENQUIRER.

THE IMPERIAL CONTINENTAL GAS ASSOCIATION.

SIR,—I observe the foot-note in your issue of the 13th inst. to your correspondent's letter of the 7th of the above subject. I feel every confidence in our Directors, and believe that they have good reason for not entering too much into detail; but I do think that they might at least inform the shareholders in what cities or towns our four millions' worth of plant is to be found.

Nov. 15, 1888.

ANOTHER SHAREHOLDER.

WATER BY MEASURE.

SIR,—“Meter” has given his views on the subject in a very able manner; and it is valuable information to your readers. But “True Measure” has not yet added anything to the discussion—not even the description of his meter. The conclusions at which “True Measure” has arrived appear to entirely hinge upon the new “meter, which he has in view.” From what I know of low-pressure water-meters, they are not so accurate as the present positive meters. The latter I have continually tested, and find them sufficiently accurate for all practical purposes.

It is quite evident that “True Measure” has not had experience, or he would not advocate meters at the end of a service. Gas men would

not do that. How many services are continually being altered, and additions made throughout houses, and taps put on direct from the mains unknown to the water companies? Is it not a temptation to steal water? Stolen it would be in thousands of cases, both intentionally and unintentionally, through the plumber's ignorance.

In conclusion, I would ask "True Measure" to kindly give us a description of his meter, if such a thing exists. It would be exceedingly interesting to all concerned.

HIGH COURT OF JUSTICE—QUEEN'S BENCH DIVISION.

WEDNESDAY, NOV. 14.

(Before Mr. Justice DENMAN and a Special Jury.)

JACKSON v. CARSHALTON GAS COMPANY.

CLAIM FOR ALLEGED DAMAGE CAUSED BY LEAKAGE OF GAS.

This was an action to recover damages in respect of injury done to the plaintiff's premises through an escape of gas from the defendant's mains, which, it was alleged, were improperly laid. The defendants denied that their pipes were out of repair; and alleged that the work done by the plaintiff was unnecessary.

Mr. KEMP, Q.C., and Mr. PAGET appeared for the plaintiff; Mr. JELF, Q.C., and Mr. R. M. BRAY for the defendants.

Mr. KEMP said the plaintiff was a gentleman who for many years had lived in the neighbourhood of Carshalton, where he had a house known as Beechwood Lodge, upon which he had expended a considerable amount of money. Near the house were four cross roads, along which were the mains of the Company. The present complaint related to the year 1885; but prior to that the plaintiff had to draw attention to the state of the mains, and he made a claim for damage done by an escape of gas, and received compensation. This showed that the Company had had their attention called to the defective state of their pipes, and that they ought to have done more than they did. In the basement of the plaintiff's house, was an arched vault, used as a wine-cellar; the bins being filled with wines of a valuable character. In October, 1885, on the plaintiff going to the cellar, he was beaten back by the strong smell of gas. As he knew there were no gas-pipes in the cellar, it was a great surprise to him to find that there could possibly be an escape in this place. A gas-fitter was sent for, but he could not discover the leak. Things having grown worse, on Oct. 26, the plaintiff gave notice to the Company that he should hold them liable for all loss and damage occasioned by the escape of gas. With a view to keep the gas out, the plaintiff had the ground excavated, the walls cemented and the floor concreted; but the gas then found its way into the premises through the stoke-hole. The Company's Inspector again visited the premises, but was unable to discover the escape. The plaintiff afterwards had a hole cut in the arch of the cellar, which allowed the gas to escape; but this thoroughly destroyed the cellar as a cellar. Upon the ground being opened outside the house, it was found that, to a considerable depth, it was saturated with gas. According to the admissions in the case, the average leakage was 12 per cent., whereas the maximum ought to be 5 per cent.; so that the Jury would readily understand there must be something wrong with the pipes. Upon the ground being excavated, it was found that the work had been abominably soamped. At the corner where there was a cellar, the pipe had been bent round, and stuffed up with white lead; and the gas escaping from here had entered an old drain-pipe which passed under the cellar. In addition to damages, the plaintiff claimed an injunction to restrain the continuance of the acts complained of.

Mr. H. Jackson, the plaintiff, was then called, and gave evidence bearing out the statement of Counsel.

In cross-examination, on being asked why he had waited for three years before commencing the action, witness said he knew that a new main was to be laid; and he wished to see whether this would cure the evil. As to the damage to the wine, he "fancied" this was due to the gas having percolated the corks. He did not know that in 1885 or 1886 he intended to make any claim for damage to the wine; and he could not produce the invoices for wine purchased since 1885, nor could he state the quantity of wine in stock in 1885, although he claimed as damage 20 per cent. upon the value of the wine in stock. The gas entered the cellar through an old disused drain, which was stopped up in May, 1887. A small service-pipe he had heard had been found broken in Mill Lane, about 200 yards from his premises; but his troubles did not cease when this pipe was mended. He could not say that the work done on his behalf, for which he claimed payment, had remedied the mischief—in fact, his workmen had been on a false scent.

James Martin, road foreman to the Local Board, deposed that in November, 1885, the Gas Company opened the road about 126 yards from the plaintiff's house; and witness and Mr. Good (the Company's Manager) had a dispute as to whether there was an escape of coal gas or sewer gas—witness being of opinion that it was coal gas. About October, the road was opened in another place for the purpose of taking up some drains; and on a light being applied, the gas blazed up. The pipe was cracked, and eaten through with rust, so much so that he could pick it to pieces with his thumb and finger. The Company took up the pipe, and put in a fresh one. Speaking generally, the gas-pipes were in a leaky condition.

Edwin Alders, gas-fitter and plumber, of Carshalton, said he visited plaintiff's house in November, 1885, and found coal gas in the cellar. Having inspected the fittings, and found them all perfect, he went outside, and detected gas coming through the ground. An excavation was made; and it was discovered that gas came through an old drain. One of the Company's men named Green was present, and said: "We must not have a light here." Witness afterwards saw the ground opened at the cross roads, and inspected the pipes. They were not properly laid; a collar having been dispensed with, and white lead used. He also inspected some of the other pipes, and found the joints "blown;" the ground round them being black. Green had admitted that the pipes were in a bad condition. If the joints were properly "set up," there would not be any leakage. He had observed about 30 or 40 joints leaking. There had been a smell of gas at plaintiff's house during the last week; it came through the shaft.

Cross-examined: Pipes could be laid in such a way that there would be no leakage. As a rule, there was always leakage, however well the pipes were laid, owing to the road sinking. In a district where there was a large amount of main without service-pipes, there would be more leakage than where the gas was driven through and sent to the services quickly; and this would be owing to the gas having to stand longer in the pipe, and so getting condensed. The Carshalton Company had a great extent of main without services thereon; so that he should expect them to have a larger percentage of loss than companies not similarly situated. His charges for work done amounted to £23.

Re-examined, witness said the ordinary leakage of a gas company was 5 per cent.; and he thought 12½ per cent. showed the pipes were faulty.

George Lowry, formerly in the employ of the defendants, deposed that, during the time he was in the employ of the Company, the pipes were in a dilapidated condition. He knew the pipes at the four cross roads near plaintiff's house. In 1885, he inspected these pipes; and one out of every two or three joints leaked. None of them were properly "set up;" the lead was just as it was run into the joint. It was a 12-inch main. There was a strong escape of gas; and the ground was very black. The T-piece, which ought to have joined with a collar, had a piece of 4-inch pipe to imitate a collar; and this was broken. He applied a light; and the gas flared up. Green was then present; and witness asked him whether he should go to the works and fetch a double collar. Green said there were none in stock. The pipe was covered over with a piece of sheet iron, and bound up with yarn and red lead, and the ground filled in.

In cross-examination, witness admitted that if the pipe was repaired with red lead and yarn, it would keep all right for some time.

Re-examined, he could not say how long it would be before the pipe would leak again when thus repaired.

Jas. Buckingham, labourer in the employ of the Carshalton Local Board, and formerly in the Gas Company's service, stated that in 1885 he was engaged in removing the main out of the path and relaying it in the road. The condition of the main was very bad. In November, 1885, he was searching the main in Paper Mill Lane; and now and then found two or three joints leaky. About 200 yards from the plaintiff's house a service-pipe was found eaten away; and on a light being applied, the trench took fire. The gully in the road near the plaintiff's house had lately been trapped; and there was now no escape of gas there.

Cross-examined: The pipe, which was broken as well as eaten away, was laid across the surface-drain. No doubt the surface-drain had weakened the ground; and a heavy waggon going over the road would help to break the pipe if it was old and rusty.

Amy Smith, formerly in plaintiff's employ as cook, testified to there being a strong smell of gas in the wine-cellar in the latter part of 1885. The windows and doors had to be kept open night and day; and she could not have a light in the kitchen, scullery, or passages.

Alfred Jacques, a reporter, produced a copy of the Director's report presented at a meeting of the Gas Company held on March 20 last, from which it appeared that the quantity of gas unaccounted for was 1,886,100 cubic feet, or 12 per cent. of the quantity made.

Mr. JELF objected to this evidence, as it related to three years after the date in question.

Mr. PAGET submitted that it went to show the present state of the main. Counsel then put in the report for the half year ending Dec. 31, 1885, from which it appeared that the quantity of gas unaccounted-for was 1,951,600 cubic feet.

Mr. JELF admitted that the percentage was about the same in all the reports.

Mr. A. Dyett, a shareholder in the Company, said that in October and November, 1885, he was frequently on the plaintiff's premises, and noticed the excavations. At the meetings of the Company, the subject of the mains was frequently discussed. At the last meeting, the Chairman made a statement with regard to the mains.

Mr. JELF objected to the evidence; but his Lordship thought the objection premature.

Examination continued: The Chairman stated at the meeting referred to that he was very sorry a larger dividend could not be paid; but it was due to the fact that there had been a large leakage.

Mr. S. Hayward, a Gas Engineer, deposed that the average percentage of leakage in the United Kingdom was 6 per cent. If 12½ per cent. of gas was unaccounted-for, it would represent an excessive amount of leakage.

Cross-examined: The amount of gas unaccounted-for in the case of the Dorking Gas Company was 12½; and the Epsom Company, 12½.

Mr. Jackson, recalled, produced various receipts from wine merchants for wine purchased in 1886 and 1887.

Mr. JELF, in submitting that there was no case to go to the jury, said an incorporated Company were not in the same position as a person who had a dangerous animal in his possession; and in the present case negligence had not been proved. All the Company had to do was to take reasonable means to prevent accidents happening; and the plaintiff could not possibly succeed without showing two things—first, negligence; and next that negligence caused the thing complained of. No evidence had been given to show that the pipes were in a bad state owing to the neglect of the defendants; or if it were, that it caused the mischief. The pipe broke owing to heavy waggons passing over ground weakened by a surface-drain, and this was sufficient to entitle the defendants to judgment. He should ask the Court to hold the plaintiff strictly to his pleadings, especially when such a stale claim was made; and the pleading was that the defendants "allowed their pipe to get out of repair," not that it was an "old pipe." There was nothing to trace the gas along the drain to the house.

Justice DENMAN said that if the defendants had caused gas to travel about there, and it had escaped from their pipes, the first question would be whether it was allowed to escape negligently. If so, it would not be so difficult for the plaintiff to make out that the gas which hurt him was gas which was negligently suffered to escape. He did not think he could withdraw the plea of negligence from the jury.

Mr. JELF said there was the third alternative, if the plaintiff showed that the gas got into the wine-cellar through the defendants' negligence—viz., the question of whether it caused the damage.

Justice DENMAN thought that was also a question for the jury.

Mr. JELF then proceeded to address the jury. He said whatever might be the rights of the parties in the case, it certainly was not an action which ought to have been brought at this late period, and under the circumstances. No one had been called to say that the wine tasted a bit the worse for the gas; and even the plaintiff only said he "fancied" it had deteriorated. Every vestige of damage ceased in 1885; but nevertheless the plaintiff persisted in claiming an injunction. It was about the coolest and most impudent case that was ever brought into Court; and if the jury were driven by any defect in the defendants' case to find against them, he submitted they should give, by way of damages, the smallest possible coin of the realm.

Mr. W. H. Green, Assistant Manager of the Bournemouth Gas and Water Company, said that from May, 1881, to February, 1886, he was in the employ of the defendants, as fitter and inspector of mains and pipes. He remembered the complaint made by the plaintiff; and by direction of Mr. Good he visited the houses. There was no escape from the service pipe or fittings in the house. On the following morning he inspected the wine-cellar; but, not being satisfied that the smell arose from coal gas, he fetched Mr. Good. There was a nasty smell in the cellar. He proceeded to strip the main; and when he came to the cellar, discovered there was a slight leakage. Upon remedying this, and finding that it made no difference to the house, he came to the conclusion that this was not the source of the mischief. The main was then stripped for a further distance of 200 or 300 yards; but nothing was found to account for the smell. There was no escape of any magnitude from the mains. Upon the mains being opened opposite Mr. Wallis's (some 200 yards from

the plaintiff's house), a service pipe was found to be broken. This pipe was laid in March, 1884. It was a new pipe; and when uncovered, was found to be sound. It was not eaten away by rust. He attributed the breakage to a heavy weight passing over the ground, or to the natural sinking of the soil. There was a surface-drain at this spot, which would weaken the ground.

Cross-examined: The annual percentage of unaccounted-for gas at the Bournemouth works was about 5 per cent. If 11 or 12 per cent. was unaccounted for, it would not indicate that the leakage was excessive. There might be an under-estimate of the quantity consumed by the public lamps. After the pipe which was found broken had been laid, the road was opened by the Local Board for the purpose of putting in new drains. As to the alleged defective collar, he was opinion that the work was properly done; but the material was not the right thing to use.

Re-examined: The escape from the collar had nothing whatever to do with the escape in plaintiff's house. In Bournemouth the services went out from the main very frequently; and as the gas passed quickly through the pipes there was not the same loss from condensation as at Carshalton. It took the defendants about two months to discover the leak.

By Justice DENMAN: He had had 17 years' experience. His theory was that the gas in the plaintiff's house came from the broken service to which he had referred; the fractured collar had nothing to do with it.

THURSDAY, NOV. 15.

On the resumption of the proceedings this morning, Mr. R. Good, Manager of the defendant Company, was examined. He stated that, on visiting the plaintiff's premises, he found there was some coal gas in the wine-cellar, mixed with sewer gas. He told Mr. Jackson it was useless for him to search for the escape; that the gas came through the drain outside; and if this was trapped, at the cost of 2s. 6d., the nuisance would be at once stopped. He also said the Company would do what was necessary to prevent the gas entering the premises. Witness confirmed the evidence given by the last witness as to the gas coming from the fractured service-pipe; and said that after the fracture was made good, the gas ceased to enter plaintiff's house. The percentage of unaccounted-for gas varied according to the size of the works. His Company had 20 miles of mains; and at places there were no services for a distance of three-quarters of a mile. Consequently there was considerable condensation. It was not fair to compare the defendant Company with the Bournemouth Gas Company. He had not received any complaint from persons in the district beside the plaintiff.

Cross-examined: In 1885, the leakage was about 10½ per cent. He did not consider this a considerable blot on the balance-sheet for such a small Company. The shareholders did not complain bitterly of the leakage.

Mr. Hudson, a wine merchant, was then called to prove that the wine could not have been injured as the plaintiff alleged by the gas.

Mr. PAGET asked if he should address his Lordship on the question of injunction.

Justice DENMAN said he certainly should not grant an injunction. Mr. JELF then summed up the defendants' case. He admitted that some gas had escaped into the cellar, though the amount had been grossly exaggerated; and it seemed to him that a great part of what had been complained of arose from sewer gas—not from coal gas at all. As to the source of the coal gas which did get into the cellar, he contended that it came from a defective service-pipe, and for this the Company were not responsible. When complaint was made, the Company did everything which reasonable men could to discover the source of the evil; and after finding the broken service, and repairing it, the mischief ceased. It was not for three years afterwards that this claim for damages was raised, in order to bolster up the claim for an injunction, which his Lordship had said there was not a shadow of foundation for. He commented rather severely on the manner in which the plaintiff's case had been conducted; and the evidence which had been given, and submitted that the plaintiff had failed entirely in the case he put forward.

Mr. KEMP addressed the jury in reply. Justice DENMAN then summed up the case. Having stated the nature of it, which was first for damages from gas escaping into his cellar and greenhouse, and, secondly, for an injunction such as was not granted, except on very strong grounds, especially if there had been considerable delay in taking proceedings, his Lordship said that the plaintiff was clearly disentitled to any injunction; and this being a question of law, he should not ask the jury any question about it. The matter of damages was to some extent affected by the same circumstance of delay; the only damage claimed for being for what occurred in the months of November and December, 1885. On this question, the facts were tolerably simple, more so perhaps than the law, because it might be argued that the defendant Company were bound so to deal with their gas as to prevent it, under any circumstances, escaping into people's houses, and that if it did, they were answerable, whether they were guilty of negligence or not. On the other hand, it might be held that the plaintiff was bound to prove more than an escape, and to establish negligence, or want of due and reasonable care on the part of the defendants, to entitle him to recover. In order to prevent future difficulty or the expense of a new trial in case his decisions on the legal point were disputed, he should ask the jury in any case to say what amount of damage they considered the plaintiff had sustained. The two questions for them would be—First, whether the escape of gas was caused by the negligence of the Company; and, secondly, whether it was so caused or not, what damages had the plaintiff in fact sustained. His Lordship then commented at length on the evidence, some of which he suggested was more suited for a Commission sitting on gas companies, or a Parliamentary Committee, than for a jury. He concluded by asking the jury to keep entirely separate and distinct the two questions they had to decide—not on the one hand under-estimating the damages because they thought there was no negligence; nor on the other hand saying the defendants were guilty of negligence, because they thought the damages were very small.

The jury, after very brief consideration, found that the defendants were not guilty of negligence; and they assessed the actual amount of damages at £5.

Mr. PAGET asked for judgment; but after a brief argument, Justice DENMAN said he was of opinion that the defendants were not liable unless negligence were found; and he should therefore give judgment in their favour.

COURT OF SESSION—OUTER HOUSE.—FRIDAY, NOV. 16.
(Before Lord WELLWOOD.)

MACKAY AND CO. v. THE EDINBURGH GASLIGHT COMPANY.

To-day Messrs. Mackay and Co., of St. Margaret's Brewery, Edinburgh, sought declarator that the Edinburgh Gaslight Company are not entitled to manufacture or store gas at their premises in Canongate in such a way as to foul, contaminate, or pollute the water in a well in St. Margaret's Brewery, and that defendants are bound to take effectual means to prevent the escape from their works into the well of gas, steam, vapour, gas washings, or noxious substances. Interdict was also asked, or payment

of £5000 as damages. The water in the well, it was stated, is peculiarly well suited, and had been used for upwards of a century, for brewing purposes. In 1883 a new gasholder was erected by the Company on their ground at Canongate, and shortly afterwards the water in the well was found to be contaminated or tainted by some foreign matter. It became worse in quality; and in 1885 pursuers were obliged to cease using the water for brewing. In July of that year they ascertained that the water was being contaminated by gas or noxious vapours coming from the defenders' works; and on the 23rd of that month pursuer's Law Agents wrote to the Company intimating that the well was being contaminated. No measures, it is said, were taken by the Company to put a stop to the contamination, and the water is now in such a foul state as to be quite unfit for brewing.

Defenders found upon the Edinburgh and Leith Corporations Gas Act of this year, and quoted several sections of the statute in which provision is made for the transfer of all the liabilities and obligations of the Company, except revenue debts, to the Corporations; and it is enacted that after the date of transfer, the Company shall only exist for the purpose of being wound up. It was pleaded that all parties were not called; that in terms of the statute the action was incompetent; that defenders, having ceased to manufacture gas, should be absolved from the declaratory conclusion of the action and from the conclusion for interdict; that no damage had been sustained by the pursuers for which defenders were liable; and that, in any view, the damages claimed were excessive.

The record was closed, and the case was sent to the procedure roll for discussion upon the preliminary pleas.

LAMBETH COUNTY COURT.—TUESDAY, NOV. 13.

(Before Mr. J. J. POWELL, Q.C., Judge.)

PROCEEDINGS UNDER THE WATER COMPANIES (REGULATION OF POWERS) ACT.

To-day the Lambeth Water Company summoned, under the recent Water Companies (Regulation of Powers) Act, 1887, several occupiers of small houses for payment of water-rate due; these being the first summonses issued under the Act. At the last moment, however, the amounts claimed were paid into Court.

Mr. WASHINGTON, who appeared for the Company, on applying for an order for costs, said he wished to explain why these proceedings were necessary, as heretofore water companies had been allowed to cut off the water for non-payment of rates, and the mere threat of doing so was generally sufficient to obtain payment of their claims. The Water Companies (Regulation of Powers) Act limited the powers of the Companies to cut off the tenant's water supply where the rates were agreed to be paid by the landlord; and in such cases it was now necessary, when the amount due was not paid, or could not be obtained from the landlord, to serve the tenant with a notice informing him that he might pay such sum, and deduct it out of the rent then due, or thereafter to become due from him to his landlord, and that if he did not do so, legal proceedings would be commenced against him for the recovery of the amount, with interest thereon and expenses. No doubt, he would be able to deduct such payments from the rent payable to his landlord. In mentioning the matter, Mr. Washington remarked that no doubt the Act was passed mainly in the interests of poor people. The Company endeavoured to make the landlord pay in the first instance, and would only resort to proceedings against tenants if the landlord failed to pay. But the Act further provided that if the rates were not paid by either landlord or tenant, the amount due became a first charge on the property. It therefore behoved all purchasers, not only of small property, but also of that large class of property which had now become as much in vogue—viz., residential flats—where the rates were paid by the landlords and not by the tenants, to see that all arrears of water-rates were paid, or complications might ensue on the transfer of the property.

Orders were made against the defendants for the costs as asked.

THE NORTHERN COAL TRADE.—The northern coal trade last week felt the unsettled state arising from the labour disputes; there being a demand for increased wages both in the steam coal trade of Northumberland and in the Durham coal trade. In the latter, whence gas coal is so largely produced, there is a desire on the part of the miners to anticipate the rise which the sliding scale is expected to give them; and it is probable that the coal-owners will grant the increase thus desired. The tendency of these demands, nevertheless, is to unsettle the trade. The steam coal business is, however, otherwise slightly weaker; the demand being less from the Baltic, though above the usual at this time of the year. In gas coal the consumption is now very high; and there is difficulty in meeting it—many of the miners evidently restricting the output, so that contracts are kept up to with difficulty. And there is also a scarcity of steamers by which to ship the coal, so that there is some reason for the delay. The rate of freight for coal from the Tyne to London has risen to 5s. 3d. per ton—which is 1s. 3d. above the usual at this period—and some expect it to advance still higher. It will be seen that very great activity characterizes the gas coal trade; and it may be added that as high as 8s. per ton free on board is now asked for best gas coal—the scarcity for early delivery being the chief cause of this. Other kinds of coal partake in a smaller degree in the improvement in price. There are all the indications of a very full demand for the winter, with one exception—viz., that as yet November has not locally brought much fog.

ORIENTAL GAS COMPANY, LIMITED.—The Directors of this Company report that, during the year ending June 30 last, there has been an improvement in the revenue; and they say the operations of the Company would have resulted in an increase of profit over the previous financial year, but for the heavy additional charge for exchange. The sum received from the sale of gas was £64,528; and from coke, tar, fittings, &c., £18,723—making together £83,251. The expenditure amounted to £49,513; the balance carried to general revenue account being £33,737. The balance of general revenue (after payment of debenture interest, and the appropriation of £1300 to reserve account) is £27,185, out of which the Directors recommend a distribution of 6 per cent., free of income-tax, payable on the 4th prox., making, with the interim dividend of 4 per cent. on June 4 last, a total of 10 per cent. for the year. There has been an increase in public lighting during the twelve months; and in private lighting, 179 new consumers were obtained, and 1423 burners added. The Company's buildings have received during the year such a complete examination and thorough repair, that they are now in a most excellent state; and the respective apparatus and holders are in good order and working condition. There has been an extension of mains for new public lights of about 2200 yards. The Directors further state that the local affairs of the Company continue to receive the careful supervision of the Resident Committee; and they also recognize the exertions of the Manager, Mr. Niven, in maintaining the prosperity of the Company. Reference is made in the report to the decease, on April 21 last, of Mr. W. White, who, as a Director for a period of about 25 years, afforded the Company the benefit of his valuable experience, and devoted himself at all times to the furtherance of its best interests. The vacancy on the Board has been filled provisionally by the appointment of Mr. H. L. Hammack.

Miscellaneous News.

THE LATE DR. WALLACE.

In the JOURNAL last week (p. 841), we recorded the death of Dr. William Wallace, of Glasgow, which took place on the 5th inst., and gave a short sketch of the deceased gentleman's career. We now supplement those particulars by the following account of Dr. Wallace's life-work (more especially in its relation to the gas industry), which has been forwarded to us by our Glasgow Correspondent:—

Dealing first with the late Dr. Wallace's work as an analyst, I may say that for a period of about ten years—from 1868 to 1877—he devoted much of his time to analyzing and testing for use in gas making upwards of 200 varieties of Scotch coals, including cannel, splints, shales, &c.; as also samples of such minerals from America, Australia, and other foreign coal-fields. His results were embraced under various heads—such as the physical properties of the coal, the composition of the volatile matters contained therein, the composition of the coke, and in respect of the gas, its yield per ton of coal, its illuminating power, its sperm value, &c. These analyses, which have been published in a collected form, are of the highest value to gas managers. I may also mention that prior to the year 1876 Dr. Wallace had made something like 2000 analyses of ironstones of various kinds, limestones, fire-clays, furnace coals, pig iron, and slag. Of these a number of examples illustrative of the Scottish iron manufacture were published in that year in a volume on "The Leading Industries of Glasgow and the West of Scotland"—one of three guide-books presented to the members of the British Association at the Glasgow meeting of 1876. For a number of years Dr. Wallace gave himself up largely to the science of sugar-refining, in which, as well as in gas matters, he was a leading authority.

I now come to Dr. Wallace's connection with the science and practice of the gas industry; this being the subject of most interest to the readers of the JOURNAL. The first published paper in this department of his work of which we can find any notice was entitled "On Some Points in the History of Coal Gas"—a subject which he treated in a lecture delivered at the annual meeting of the North British Association of Gas Managers in 1869. His next paper was "On the Economical Combustion of Coal Gas." It was an experimental discourse which he gave in March, 1874, to the Philosophical Society of Glasgow, whose membership he entered in the year 1851. This was a most comprehensive and interesting paper; and it showed that Dr. Wallace had an extensive and intimate acquaintance with the gas-burners that had up to that time been brought into notice. In the year 1874 the members of the North British Association of Gas Managers had the pleasure of hearing a discourse from Dr. Wallace on the influence of pressure on the illuminating power of coal gas; and on that occasion he also had a paper on a new system of photometry for gas. Three years later, at the annual meeting of the same Association held in Stirling, he gave another lecture, the subject of which was "The Bunsen Burner." In the course of his exceedingly interesting remarks, he not only described the burner in detail and the character of the flame produced by it, but also showed the various modes of applying it in practice in the laboratory.

A marked recognition of the position now secured by Dr. Wallace in connection with the development of the illuminating properties of coal gas was made in the year 1877, at the Plymouth meeting of the British Association, on which occasion a Committee, which included himself, Professor Dittmar, and the late Mr. T. Wills, was constituted for the purpose of reporting on the best means for the development of light from coal gas of different qualities. Dr. Wallace was appointed Secretary, or "Reporter"; and in the following year, at the Dublin meeting of the Association, Part I. of the report, which had been drawn up by Dr. Wallace, was submitted. (See JOURNAL, Vol. XXXII., p. 423.) Part II. of the report (which was drawn up by Mr. J. Pattinson, of Newcastle-on-Tyne, who had taken the place of Mr. Wills on the Committee) dealt chiefly with gas made from common bituminous coal of the Newcastle and other coal-fields; while Dr. Wallace's portion of the report had reference chiefly to the use of cannel gas, such as is supplied in most towns of Scotland. (Part II. of the report will be found in Vol. XXXVI. of the JOURNAL, p. 376.)

In the year 1879 Dr. Wallace communicated to the Philosophical Society of Glasgow a paper bearing the title, "On the Heating Power of Coal Gas of Different Qualities," in the course of which he worked out the general fact that gas of low illuminating power is the cheapest for heating purposes. About this time he also gave attention to the condition in which sulphur exists in coal—a subject with which he dealt in a paper read before the Chemical Section of that Society. Within the last three or four years the deceased was much associated with Mr. W. Poulis, the General Manager of the Glasgow Corporation Gas Undertaking, in prosecuting an inquiry as to the propriety of reducing the illuminating power of the gas made in Glasgow, in consequence of the Corporation Gas Committee having resolved to ask for parliamentary powers to make an important change in this direction. The reports prepared for the Committee (chiefly by Dr. Wallace) have appeared in the JOURNAL as they were rendered available; and consequently it is not necessary to refer to them with any detail.

As makers of gas-burners and patentees of new gas-lamps are well aware, Dr. Wallace was extensively consulted in reference to such inventions, and commissioned to report upon them professionally. One of his most important pieces of work in connection with gas matters was to serve as a juror in the exhibition of gas and electric lighting appliances held under the auspices of the Philosophical Society in the year 1880. The work he had to do on that occasion, in the way of testing and reporting upon gas-meters, governors, &c., was very great, and of permanent value. His fellow-jurors freely admit that the work was his and not theirs.

The deceased was largely employed by the Glasgow municipal authorities from time to time to inspect and report upon sewage systems in operation in various parts of the country; and other local authorities had his professional advice on many occasions in reference both to sewage schemes and water supply. One of the "Glasgow Health Lectures" was delivered by him in 1881; his subject being "On Water and Water Supply." On another occasion he delivered a course of four public lectures under the auspices of the Lord Provost, Magistrates, and Town Council of Glasgow, when he dealt with "The Air of Towns," "The Water Supply of Towns," "The Disposal of Sewage," and "Food and its Preservation." At the Glasgow Congress of the Sanitary Institute, he read a paper on "Some Sanitary Aspects of House Construction." In this connection I may state that one of his Philosophical Society papers was on "Air and Water in Relation to Public Health;" and another on "The Germ Theory of Putrefaction."

I have already mentioned that Dr. Wallace became a member of the Philosophical Society in 1851; and I may now add that he was elected a member of the Council in November, 1870. He entered the Council again in 1879, to serve a second term of three years. This was followed by his election to the office of President, which he filled with the greatest credit to himself and success to the Society for another period of three

years. He was an honorary member of The Gas Institute, and of the North British Association of Gas Managers, and a Fellow of the Royal Society of Edinburgh, of the Chemical Society, and of the Institute of Chemistry. Dr. Wallace will long be remembered as a zealous servant of science, an excellent citizen, and a faithful friend. In testimony of the respect in which he was held by his fellow-members of the Glasgow and Scottish Section of the Society of Chemical Industry, the first meeting of the present session, which was to have taken place on the 6th inst., was postponed till the 12th. A few members assembled on the first-named date, when the Vice-Chairman (Mr. R. R. Tatlock) alluded in feeling terms to the loss the Society had sustained in the death of Dr. Wallace, and of the loss which the event had brought to him personally; the deceased having been his partner in business for a long series of years, during which, he said, the slightest dissension had never arisen between himself and his friend thus prematurely removed.

SINGAPORE GAS COMPANY, LIMITED.

An Extraordinary General Meeting of this Company was held last Tuesday, at the Cannon Street Hotel, E.C.—Mr. R. S. FOREMAN in the chair.

The SECRETARY (Mr. Robert King) read the notice convening the meeting; and the Directors' report and the statement of accounts, an epitome of which appeared in the JOURNAL last week (p. 838), were taken as read.

The CHAIRMAN said he would only detain the shareholders with a few remarks before formally moving the adoption of the report. As a consequence, he observed, of the increased use of kerosene oil as an illuminant, by reason of its present low price, and the cheapness with which the German and American lamps and other fittings could be supplied for its service, the gas and meter rental from private sources, and necessarily also the fittings department, showed some reduction as compared with the previous and corresponding half years. On the other hand, the public lighting exhibited a decided increase. Forty-eight additional lamps had been fixed and lighted within the last few months; and the indications of further development in this direction were most encouraging. Whilst on this subject, he might be allowed to call the shareholders' attention to a paragraph which appeared in *The Times* on Sept. 15 last, which some of them probably had noticed, headed "Kerosene in China," from which the following was an extract:—"The Viceroy of Canton, the famous Chang Chingtung, has addressed a memorial to the Emperor which contained a terrible indictment of kerosene oil. He brings a long series of charges against it. Not long ago it caused the destruction of 400 houses in Swatow; just before it burnt a steamer to the water's edge, taking the lives of about 800 persons; shortly afterwards, it burnt out 1000 families in Canton, and destroyed 10 million dollars' worth of property. It is responsible for nine-tenths of the fires occurring every year in the city of Canton. Therefore, the Viceroy denounces it." There was much more, the Chairman continued, in the article to a like purport; but the foregoing extract, he thought, was sufficient to show that, notwithstanding the low price at which this commodity could be supplied, its introduction into some parts of the East was not regarded as altogether one of unqualified advantage. In regard to the residual products, he might mention that they had met with a brisk demand, and realized good prices. The collections, which required constant and unremitting attention, had been thoroughly well maintained, and the outstandings reduced to the lowest possible point. Considerable improvements had been carried out on the works during the half year—notably the old coal-stores, which were put up when the Company was first established, had been strongly but cheaply reconstructed. The level of the flooring had been raised, and also the ground in other parts of the works hitherto subject to flooding at high spring tides. The two new purifiers recently erected were also working satisfactorily. The whole of the material for a new gasholder and tank, after a careful inspection by the Engineer (Mr. R. King), was landed on the works at Singapore early in October; and the whole of the work of erection, including repairs to one of the original holders, was expected to be completed early in the commencement of the ensuing year. Before concluding, he might mention that, as the proprietors had probably noticed, the accounts were sent out on the present occasion with the signature of only one of the Auditors appended. This was in consequence of the absence of Mr. W. T. Morrison from England at the time appointed for holding the audit; so that the whole of this work devolved upon Mr. Alfred Williams. He then moved—"That the report, with the balance-sheet thereto attached, be received, adopted, and entered on the minutes."

Mr. SMITH said he should have pleasure in seconding the report. He thought he might venture to say that the shareholders were much obliged for the free and ample explanation which the Chairman had given them. Looking at the profit and loss account, and the revenue account, he considered the whole a very fair and reasonable working statement. Although there were items with which they had at times to find fault, they all knew that in such undertakings as this there were always variations. He noticed that the gas-rental and fittings account was rather less than before; but to this he attached little importance, because this was simply one half year. From the increase in the number of public lamps and the improvement in the value of residuals, together with the revival of trade, he was under the impression that the accounts for the whole year would prove satisfactory. Compared with the corresponding half year, the accounts were very similar. He was glad to see the Company in a prosperous condition, which he trusted would still continue in the future.

Mr. SPENCER said that at the last meeting he referred to the leakage; and he should like to know how it stood now.

The SECRETARY replied that it amounted to about 14 per cent.

Mr. SPENCER remarked that this was better; but, of course, it still was a considerable amount for leakage.

The SECRETARY observed that they were troubled at Singapore with the steam-roller of the Municipality. It broke the Company's mains; and they were bothered a good deal with them.

The CHAIRMAN said that whenever it was brought home to the Municipality, they always paid for any damage.

Mr. SPENCER inquired what was the mileage of the mains.

The SECRETARY replied about 35 or 36 miles.

Mr. SMITH expressed the opinion that a leakage of 14 per cent. was not extravagant. The ground in which the mains were laid was, he said, very watery, and the district a scattered one.

Mr. WILLIAMS remarked that with a leakage of 14 per cent., they might depend upon it that they were not doing badly.

The motion was then carried unanimously.

The CHAIRMAN proposed the declaration of a dividend on the ordinary share capital at the rate of 7½ per cent. per annum, less income-tax; such dividend to be payable on the 20th inst.

Mr. F. A. M. NICOL seconded the motion, which was agreed to.

On the motion of Mr. SMITH, seconded by Mr. NEWTON, a vote of thanks was passed to the Chairman and Directors, for the satisfactory manner in which they had conducted the affairs of the Company during the past half year.

The CHAIRMAN, in acknowledging the compliment on behalf of himself

and his co-Directors, observed that there was no doubt the Board had of late had a very anxious time. The strike in the coal trade and the advance in freight had caused the Directors considerable anxiety. They would do their best in the future, as they had done in the past, to merit the shareholders' approbation.

A vote of thanks was unanimously passed to the officers of the Company; recognition being made of the trouble Mr. A. Williams had taken in doing double duty in auditing the accounts.

The SECRETARY and Mr. WILLIAMS having both suitably responded to the vote, the proceedings terminated.

PARTICK, HILLHEAD, AND MARYHILL GAS COMPANY.

THE POSITION OF THE PREFERENCE SHAREHOLDERS.

In the JOURNAL for the 6th inst. (p. 810), it was stated that an extraordinary general meeting of the above-named Company was to be held on the following Thursday for the purpose of considering resolutions authorizing the Directors (1) to enter into an agreement with the Corporation of Glasgow for the sale to them of the whole of the Company's undertaking and assets, at the net price, over and above the Company's liabilities, of £122,370; and (2) sanctioning the payment to the holders of the 5½ per cent. preference shares of the amount of their shares and 10 per cent. premium, and to the holders of the ordinary shares of the amount of their shares, less 10 per cent. discount. In view of the proposal contained in the second resolution, the preference shareholders had a meeting on the previous Monday, at which it was unanimously resolved that the terms offered by the Directors were inequitable, and that though they might agree to the purchase of the Company's undertaking by the Corporation at the lump sum of £122,370, they could not agree to accept the proportion proposed to be allotted to them. A Committee was formed to obtain the opinion of Counsel on the question, and generally to attend to the interests of the preference shareholders. The Directors becoming acquainted with this determination, also sought the advice of Counsel, which appears to have been similar to that given in answer to the question of the preference shareholders. At the meeting on the 8th inst., the Chairman (Mr. H. Cowan) read a statement on behalf of the Directors, in which, after announcing, in regard to the first resolution, that the proposed sale of the undertaking to the Corporation of Glasgow had been approved of by a large proportion of the shareholders, they said that, as opposition to the second resolution might be expected, they had deemed it advisable to take Counsel's opinion on the whole position. This they had done; and the reply received, established the following points:—(1) That the first resolution was undoubtedly competent, and, if passed by the requisite majority, would authorize the sale of the works at the price stated. (2) That by law the assets of the Company on its dissolution would fall to be divided among the shareholders *pro rata*, without reference to whether the shares were preference or ordinary; and that, as the second resolution would have the effect of conferring upon the preference shareholders a benefit as in a question with the ordinary shareholders beyond what the law allows, it was doubtful whether that resolution, if passed, could be carried into effect without the consent of every shareholder of the Company. On receipt of this opinion, and on finding that a unanimous acceptance of the second resolution was not to be expected, the Directors found it necessary carefully to reconsider the position. It would, of course, have been open to them to propose the first resolution, of the validity of which there was no possible doubt, and simply to drop the second, on the legality of which doubt had been thrown; but, on consideration, they felt that this course would not be fair to absent shareholders, who might have granted proxies on the understanding that both resolutions were to be submitted. The Directors accordingly came to the conclusion that the proper course to take was not to submit at that meeting either of the resolutions, but to hold another meeting at as early a date as possible for the purpose of considering and, if so resolved, of adopting the first resolution only. This course involved the abandonment of the idea of putting the preference shareholders on a better footing, in the division of the money received for the undertaking, than the ordinary shareholders; but, however willing the Directors might be that the preference shareholders should be dealt with specially, they found it to be impossible, without incurring serious risk, for the Company to pass any resolution altering in any way the statutory mode of dividing the price of the Company's works if sold. After this statement had been read, it was unanimously resolved to dissolve the meeting; not a word of objection being raised by the preference shareholders. The result of the opinion of Counsel therefore is, that whatever sum the Corporation of Glasgow decide to give as a premium on the preference stock in their scheme of purchase must be divided equally with the ordinary shareholders. As for the 20,000 ordinary and 6000 preference shares, each of £5, the proposed purchase price is £122,370, this comes to only about £4 14s. 1½d. each; so that when the general division comes, the preference shares are likely to be levelled down from £5 10s., and the ordinary shares levelled up from £4 10s., to the above-named figure. In the meantime, the holders of the former will continue to get 5½ per cent., and the holders of the latter 4 per cent. dividend on their shares. As many of these were purchased when the price was down to 37s. 6d., or from that to 45s. each, the holders will not have much cause to complain.

THE ELECTRIC LIGHTING AT LEAMINGTON.—On Monday and Tuesday evenings last week, the first instalments of the improvements now being carried out in connection with the electric lighting system at Leamington were completed, and brought into use. The new lights are of the arc type, ranging from 300 down to 50 candle power. They are placed at intervals along the Parade; and their brilliancy detracts somewhat from the power of the ordinary electric lights.

THE PUBLIC LIGHTING OF TWERTON, NEAR BATH.—After having had before them, at various times during the past 17 years, the subject of lighting the district, the inhabitants of Twerton have now decided to adopt gas. At a largely attended meeting held last week, a Committee was appointed to take up the matter; and a sum of £200 placed at their disposal for the first year, on the understanding that they are to "make it go as far as possible." This will mean a rate of 3d. or 4d. in the pound.

THE ELECTRIC LIGHTING OF KENSINGTON.—The question of the lighting of the parish of Kensington by electricity came up at the meeting of the Kensington Vestry last week. Mr. Lindsay objected to mapping out the parish, as was proposed, to four companies; and said that, though the Committee pretended not to want to grant a monopoly, this would be virtually created by the adoption of their proposal. He, therefore, moved that the Vestry should give authority to the whole seven electric light companies who had applied for permission to supply light, without allotting any particular part of the area. The proposal was carried by 38 votes to 19. The Chairman of the Committee (Mr. Jordan) and two members resigned their positions in consequence of this decision. Ultimately the Vestry reconsidered their decision, and postponed the matter for a fortnight.

LEEDS CORPORATION GAS SUPPLY.

THE COAL QUESTION.

At the Meeting of the Leeds Town Council last Wednesday, the MAYOR (Mr. Alderman Ward) in the chair—the question of the quality of the coal supplied to the Corporation, which, as our readers are aware, had been under investigation by a Special Committee, was discussed.

Mr. GILSTON, in moving the adoption of the Gas Committee's minutes referred to statements made during the past month about the quality of the Leeds gas, and more particularly about the coal. The Council were aware, he said, that Mr. Ellis Lever, had had interviews with the Committee on the question of the coal supplied to them. A more favourable time for the purpose could not have happened, as finding themselves on the eve of a coal crisis, the Committee had for several weeks been pressing the contractors to send in every ton of coal they could possibly spare; and if ever there was a time when coal-owners would be likely to send in surplus stock, they might then have been expected to do it. Every facility was given to Mr. Lever to secure samples of the coal supplied; and tests were made at the works, and also by the Borough Analyst (Mr. T. Fairley, F.C.S.), in the presence of Mr. J. Paterson, F.G.S., of Warrington, on behalf of Mr. Lever; and the results were such as to show that all the noise made about the way in which the Gas Committee were allowing the ratepayers to be swindled to the extent of 2000 tons of coal a year was as great a piece of humbug as was ever spoken in the borough. Mr. Lever never suggested that the Committee did not get the weight of coal they paid for; and as to the results of the tests of the different kinds of coal selected by Mr. Lever and the Committee, they showed them to be capable of producing per ton respectively 11,600 cubic feet of gas of 26½-candle illuminating power, 11,700 cubic feet of 26½-candle, and 11,150 cubic feet of 28-candle. The coal in the second case was selected as worthless; while the third was taken as slack. As bearing upon the Gas Committee's work, he had taken out details showing the improvement made under every head in the year 1888, as compared with the year ending June, 1885. In 1885 they averaged 9036 cubic feet of gas per ton of coal; and in 1888, 9964 cubic feet. The cost per ton in 1885 was 8½s.; in 1888, 8½s. In 1885 they obtained 13¾ gallons of tar per ton of coal; in 1888, 13½ gallons. In 1885, 32¾ gallons of ammoniacal liquor; in 1888, 34½ gallons. In 1885, the gas produced cost 11½d. per 1000 feet; in 1888, 9½d. A severe crisis had been passed through; but in the half year ending June, 1888, the deficit had been brought down to only £1600. They had increased the contract for tar from 11s. to 21s. and 26s. per ton; and as they had made 15,000 tons during the present year, there would be an influx into their coffers of £10,000 or £12,000 without any increased consumption of gas. So that they had seen the last year of their deficits. He had no hesitation in saying that at the end of the next financial year would be seen the beginning of a surplus which would be little short of £10,000 in favour of the ratepayers.

Mr. DYSON seconded the motion, and remarked that the Committee could not have published Mr. Lever's report without the risk of an action for libel.

Mr. GILSTON said the Committee intended to print and distribute the report.

Mr. LAYCOCK asked Mr. Willey whether he had been misreported as saying at a meeting in the South Ward that "they might take it that the ratepayers had for many years been paying for thousands and thousands of pounds worth of coal which they had not been getting?"

Mr. WILLEY said the report was substantially correct. He really said "thousands and thousands of pounds worth of coal, the value of which they had not received." This he adhered to, and was prepared to prove. He was amazed, in going through the books of tests in the Gas Manager's office, to find that the Gas Committee had been passing coal without proper examination, and that from January last at least one-half of the coal passed into stock as equal to sample was below it from 2 to 15 per cent. In some cases it was 20 to 29 per cent. lower than the contract sample. When he questioned Mr. Lupton, the Secretary, he found that such faults were only complained of by letter, but no deduction had been made, except in one case. It was bad and wrong commercially thus to pass inferior coal; and what he said was perfectly true. These things did not come before the Gas Committee. The tests were sent only to the Secretary, who handed them to the Chairman of the Gas Committee, and then the matter dropped. These tests the Committee should have been informed of.

Alderman SCARR said the Lever question had been an unpleasant business for him, because members of the Committee thought he had given Mr. Lever more liberty in examining the coal than he ought to have done. Mr. Gilston looked upon Mr. Lever as a coal dealer wishing to get advantages as a coal dealer rather than as one who had exposed a scandal at Salford. It would have been a fatally unwise thing if the Committee had so regarded him; and the position they occupied that day was owing to the fact that they followed the better course. From what had arisen in connection with these investigations, he had drawn certain deductions; and he should be unfaithful to the Gas Committee and to the town if he did not give them the results of his views. Mr. Lupton, the Secretary, stated to Mr. Lever that certain deficiencies had occurred in coal from one colliery to the extent of 22 per cent. When he looked into this, he found that the tester discovered the coal was not up to the standard on the 4th of October, the test was not made till the 12th, the report was given to Mr. Lupton on the 15th, and the colliery was not communicated with until the 20th. Between the discovery of the discrepancy and the 23rd of October, the Committee received 292 tons of coal. As a commercial man, he was of opinion that this was not business. The moment he found that there was any deficiency taking place in the quality of the goods delivered to him, he stopped the delivery, pointed the matter out, and had it rectified. The matter ought to have been looked into at once. It was not sufficient that a young man should test the coals half-a-dozen times in a year; but caution demanded that a man fully understanding the question should examine every truckload of coal that came to the works. He did not say that there had been any frauds practised at the Leeds Gas-Works; but there had been very great room for frauds. If it was true that 4 per cent. of "hub" was admitted, they were receiving 8000 tons of coal per annum lower than sample. He believed that the inquiry would result in the better management of the gas-works.

Mr. ARNOLD LUTON denied that it was possible, under the conditions for sending coal out, to forward trucks of coal which should be in the nicest degree equal to sample. Coal might be deficient, without any design on the part of the contractor.

Mr. GILSTON, in reply, said it was the practice at the gas-works to pass coal in bulk as satisfactory if it were within 4 per cent. of the value of the sample. The Works Managers had power to send coal to the tester if its quality was at all in question. He himself complained of the neglect referred to by the ex-Mayor (Mr. Alderman Scarr). But between the periods mentioned by him, exception was not taken to a single truck; and to his (Mr. Gilston's) mind this in itself was evidence of the quality of the coal. He dealt with Mr. Ellis Lever as a reformer of abuses, as well as a coal dealer. But that gentleman made two insinuations which disturbed his mind; and if the ex-Mayor had been in his position, he would also have felt that an injustice had been done. He had tried to do his

duty, and no more. As to Mr. Willey's complaint, he could prove that in one year 13 tests were made of a certain supply of coal, which only gave an average of 2½ per cent. below the sample test from which the purchase was made. No contractor would sell coal if every truck were to be submitted to fine chemical tests. The fact that tests had been made at the gas-works for two years, was in itself an incentive to the coal contractors to supply an article similar to that tendered for.

The minutes were then adopted.

BURY CORPORATION GAS SUPPLY.

THE PRICE OF GAS IN THE OUT-TOWNSHIPS.

At the Meeting of the Bury Town Council on the 9th inst., the Mayor (Mr. Alderman Smethurst) presiding,

Mr. EASTHAM, in accordance with notice, moved—"That the resolution of the Gas Committee passed on the 18th of June last, and confirmed by the Council on the 5th of July last, so far as the same relates to fixing the price of gas to consumers outside the borough and in the newly-added areas at 3s. 1d. per 1000 cubic feet, less 2d. for prompt payment, be rescinded, and that the price charged to such consumers be 2s. 7d., less 1d. for prompt payment." He said the original resolution was sprung upon the Council, who had not time to think about it. There was a determined opposition in the outside districts to the enormous difference of 50 per cent. between the price in the added areas and other parts of the borough. The consumers were resorting to oil, which was stated to be cheaper and better than gas, from a feeling of being unfairly treated. After the recent visit to the gas-works, the Manager (Mr. W. Woodward) told them that, in consequence of the reduction in price inside the borough, about 500,000 cubic feet of gas per week were being consumed. The moral was that if they charged the added consumers a reasonable price, the consumption would increase, the loss in the shape of waste and condensation lessened, their income increased, and a larger revenue would accrue. They should treat the outsiders not as foreigners, but as themselves.

Mr. METCALF seconded the motion, not on the ground of price, but of the outsiders being charged 50 per cent. more than those inside the borough. Previous to those districts being brought into the borough, they had gas at an additional price of 6d. per 1000 feet; but now they were charged a greater difference, and there was a strong feeling against this.

Alderman BURROW was sorry the question had arisen, as half the year had already gone. Two quarters' bills had, he said, been paid in most instances; and it would be inconvenient and unusual to rescind a resolution, alter the accounts, and refund the money. He hoped the motion would not be entertained. He wished to have a year's experience of the arrangement. The great increase in the consumption of gas had occurred in the outside district, where the price had not been reduced. The increase inside was 3½ per cent., and outside 9½ up to last month. There were other reasons why no alteration should be made.

Mr. MELLOR said the price was fixed and the estimates of the cost of working based on there being no profit on the works; so that if the motion were passed there would be a loss of 6d. per 1000 cubic feet. They could only meet the deficiency by raising the charge inside by 3d. per 1000 feet, and dropping the price outside a like amount. He asked Mr. Eastham to withdraw his motion.

Alderman PEERS said that if the motion were carried, it would upset the whole calculations on which they reduced the price so that no profit should be made. He was not in favour of an increase in the price to outsiders; but in the inside district they had a water-rate of 2d. in the pound which the outsiders would not pay. They were going to Parliament to get relief from a 10d. rate. Did the added areas contribute to this rate? Not a penny. To show how little the outside people had to complain of, he had a list of the prices charged for gas in the districts round about. The outside people of Bury paid 2s. 11d. net; Radcliffe, 3s. 5d. to 4s.; Accrington, 3s. 1d.; Blackburn, 3s. 5d.; Bolton, 3s.; Burnley, 3s. 3d.; Ramsbottom, 3s. 6d. to 3s. 11d. Where did the injustice come in? [Mr. METCALF: It is not the price. It is the difference between the rates.] There was also a difference between a 10d. and a 2d. rate and the amount paid by outsiders. Inside, the rate was compulsory; outside, people had the option of using gas or not. Yet the Corporation were asked to make gas at a low rate for those who did not contribute towards the expenses of the borough.

Mr. MOSLEY said to rescind the resolution in the middle of the year would be absurd. It was not fair to the Committee to bind them down to charge 2s. 7d. per 1000 feet to outsiders.

Alderman HORRIDGE said that when the price was 4s. per 1000 feet the difference was only 6d., which was enough now. He objected to the water question being mixed up with the gas question. They could not work amicably with the added areas by charging a higher price for gas.

Mr. BENTLEY pointed out that when the Corporation applied for the Local Act of 1885, it was pleaded that the outsiders did not wish to be saddled with the liabilities or assets of the Corporation; they wished to be considered as customers and not as partners. Now, however, as to gas, they wished to be partners. He would allow the added areas to have gas at the same price as insiders if those outside would pay the rates that were paid inside.

The motion was withdrawn.

LYMM LOCAL BOARD GAS-WORKS.

EXTENSION OF THE PLANT.

We learn from a local paper that the alterations in the plant at the Lymm Gas-Works, for the carrying out of which the Chairman of the Gas Committee has been for a long time agitating, have now been completed. In view of this circumstance, it may not be uninteresting to glance at the progress of the undertaking in the past decade. Some ten years ago, the amount of gas consumed daily at this time of the year averaged about 20,000 cubic feet; at present it is something like double this quantity. On certain days last winter, it even reached 50,000 cubic feet in a day; but this can scarcely be said to be the present normal output on short winter days. With double the consumption in ten years, it is only natural to suppose that in the same time there must have been some considerable changes in the apparatus. There used to be but nine retorts; whereas now there are 24 of increased capacity, which allows a margin of five, or occasionally ten, being out of use. In the purification process, after the tar is extracted, the gas passes through the old washer (which remains much in the same position as formerly), after which it passes into an "Eclipse" scrubber-washer, made by Messrs. Clapham Bros., of Keighley. This machine is specially designed to divest the gas of all traces of ammonia. After the gas has entered, it is forced through ten chambers, each of which is packed with wooden balls 1½ inches in diameter, which are kept constantly revolving by a small engine. Each ball has a hole ¼ inch in diameter through it; and by this means the gas is broken up. As the chambers revolve in water, the latter becomes charged with the ammonia in the gas. The gas passes thence into the next chamber, where the process is repeated; and then to the next, until it passes through the tenth and last chamber.

Long before it reaches it, however, there is not a trace of ammonia left. This machine has only been in operation a short time, but is giving eminent satisfaction. The water remains in the first chamber until it registers 5° Twaddell. The gas next passes to the lime purifiers, of which there are four—no additions having been made since the works were erected. Of course they are not adequate to the work required of them; and their improvement is urgently called for. A new station meter, supplied by the Gas-Meter Company, of Oldham and London, was brought into use at the beginning of the present month. It is capable of passing 180,000 cubic feet of gas per day. The storage capacity of the works is another weak point which will have to engage the attention of the Committee. It is only equal to 43,000 cubic feet; and the holder is defective. We may add, in reference to the "Eclipse" washer-scrubber, that Messrs. Clapham Bros. are just now busily engaged upon the manufacture of these machines, having received a large repeat order for two, each of a daily capacity of 4 million cubic feet, and one of 2 million cubic feet, from a gas company who put in one of these appliances about four years ago.

HUDDERSFIELD CORPORATION GAS AND WATER SUPPLY.

At the Meeting of the Huddersfield Corporation on the 9th inst., the Mayor (Mr. Alderman J. Brooke) addressed a few observations to the Council bearing on the work of the various departments during his year of office. Alluding to the gas undertaking, he said the canal and coal used in 1887 was 40,690 tons; in 1888, it was 41,638 tons—showing an increase of 948 tons. The gas sent out and consumed in 1887 was 433,626,000 cubic feet; in 1888 it was 447,900,000 cubic feet—showing an increase of 14,274,000 cubic feet, or 3.29 per cent. The average illuminating power of the gas for the year 1887 was 20.01 sperm candles; in 1888 it was 20.10 sperm candles. The extension of the gas-works this year has been unusually large, involving an outlay of nearly £17,000. This had been necessary in order to make provision for the constantly increasing demand for gas. The new works were now completed. There had also been a new gasholder erected, having a capacity of 1,120,000 cubic feet, and this was now at work. On the 27th of September, the new works were started (the new holder included) in the presence of the Gas Committee, when everything passed off smoothly and evenly, without difficulty or accident, and all had continued in excellent order. There had been an increase of about 400 new consumers during the year; and the mains had been extended by a mile. The whole of the works and mains had been kept in thorough repair and efficiency. The profits from the gas-works this year was £8479 11s. 6d., as against £7714 15s. 6d. in 1887. With respect to the water undertaking, the number of gallons of water supplied for trade purposes inside the borough during the past year had been 360,563,000; outside the borough, 67,144,000 gallons—making a total of 427,707,000 gallons, as compared with 436,609,000 gallons last year. The population supplied inside the borough was 97,280; outside, 35,135—making a total of 132,415, as compared with 129,975 at the same time last year. The number of houses added for water supply during the year was 292 inside the borough, and 196 outside—making a total of 488. The number of meters fixed was 398 inside the borough, and 123 outside—making a total of 521, as compared with 503 last year. The length of mains now laid was as follows:—Trunk mains, 30 miles 44½ yards; distribution mains outside the borough, 115 miles 139 yards; inside the borough, 68 miles 643 yards—making a total of 213 miles 1228 yards. The net water-rental during the year had been £45,447; during the previous year it amounted to £42,122—showing an advance of £3325. The water-works revenue account showed the income for the year to be £1569 18s. 6d. in excess of the expenditure. This surplus had been applied towards reducing the amount of accumulation of deficiencies in previous years; and the balance remaining it was expected would be discharged in about three or four years, if not sooner. All available resources for obtaining water that could be brought to the town deserved the early and anxious consideration of the Council. The present consumption of water was about 3½ million gallons per day. The sources of supply were calculated to yield (say) 4½ million gallons per day, exclusive of compensation water. This left 1½ million gallons daily in favour of supply over demand. If the two reservoirs proposed were made in the Wessenden Valley, they would probably add 2 million gallons per day to the supply, which would amount to 3½ million gallons daily to meet the growing demand. The rate of increase in the demand for the last five years had been about 40 million gallons per annum. At this rate the consumption would overtake the supply in 30 years. He held the opinion that all the surplus water would be utilized long before 30 years had elapsed. Whenever this event happened, were it sooner or later, the prosperity of the town and district would receive a deadly blow. His last words on this important subject were the expression of an earnest conviction that it was incumbent upon the Council to endeavour to obtain, as soon as possible, a cheap, abundant, and practically inexhaustible supply of pure water for domestic and manufacturing purposes, so that the prosperity of the town should be secured for untold years to come.

BURNHAM WATER SUPPLY.—Mr. T. Codrington, C.E., held an inquiry at Burnham, Somerset, last Tuesday, for the purpose of receiving evidence with regard to the application made by the Burnham Local Board to the Local Government Board for sanction to borrow £2000 for works of water supply. It was stated that most of the amount was required for the construction of gullies and trenches. Evidence having been taken, the Inspector visited the pumping station at Brent Knoll.

LONG EATON WATER SUPPLY.—Last Wednesday a special meeting of the Long Eaton Local Board was held to consider the question of a supply of water.—Mr. J. Orchard, J.P., presiding. After a long discussion, it was decided to apply for the necessary powers to procure a good supply of water. Another resolution was passed that the Clerk should watch an effort by an outside syndicate to obtain power to supply water to the Long Eaton district. A deputation was appointed to consult the Nottingham Corporation as to supplying the township with water from their works.

PROPOSED CONSTANT WATER SUPPLY IN WIMBLEDON.—At the meeting of the Wimbledon Local Board on the 7th inst., the Clerk reported the receipt of a letter from the Secretary of the Lambeth Water Company (Mr. S. H. Lonttit) with reference to the proposed constant supply of water to South Wimbledon. The deputation from the Board met the writer in conference on Oct. 10 last, when the Secretary pointed out that Wimbledon being outside the area defined by the Metropolitan Water Act, 1852, the Board of Trade regulations as to prescribed fittings, framed under the Act of 1871, could not be enforced, but that the Company had power under the Water-Works Clauses Act, 1817, and their own Act of 1848, to out off the supply to houses in cases of waste or misuse of water due to inefficient fittings. The Directors would give a constant supply to a part of the district as an experiment; and it would depend on the inhabitants themselves whether it was continued and extended throughout the parish. The Company, however, reserved to themselves the right to revert to the intermittent system should they be unable to satisfactorily check waste. The letter was referred to the Road and Drainage Committee.

THE PRICE OF GAS AND WATER IN LANCASHIRE.

In the JOURNAL for Sept. 25 last (p. 558), we published some particulars in reference to the price of gas in various Lancashire towns, from a return compiled by Mr. J. H. Bailey, the Borough Treasurer of Blackburn. A similar, but more extensive table has now been issued by Mr. Carter, the Treasurer to the Corporation of Preston, from which we take the following figures showing the price of gas per 1000 cubic feet, the charge in the pound for water used for domestic purposes on a house of £15 rateable value, and the total local rates:—

Name of Town.	Population.	Rateable Value.	Charge for Water.	Price of Gas.	Total Rates.
		£	s. d.	s. d.	s. d.
Accrington	31,435	120,872	1 3½	3 1	4 2
Ashton-under-Lyne	39,600	141,426	1 10	2 4	4 6
Barrow-in-Furness	52,000	223,210	1 0*	3 6	3 10
Blackburn	120,000	408,884	1 7-2	2 9½	4 8
Blackpool	20,000	155,117	1 0	2 6	4 2
Bolton	110,000	407,086	1 5½	2 6	4 10
Bradford	224,507	979,864	1 6	2 3	5 4
Brighton	119,983	680,356	0 9	3 1	4 8
Bristol	206,874	984,490	—	—	4 11½
Burnley	78,000	224,966	1 0	2 3	5 1.
Burton-on-Trent	46,500	213,912	—	—	3 11
Cardiff	120,900	681,961	1 2-4	2 6	4 5½
Carlisle	42,000	153,355	0 10½	2 6	3 10
Chester	37,000	161,811	1 8	3 4	4 6

Wolverhampton	81,000	259,847	1 3	2 6	5 8½
York	70,800	236,158	1 0	2 3	4 2

* Charged on gross rental.

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis during the past month was 161,994,888 gallons, against 159,115,975 gallons in the corresponding month of 1887. The number of houses served last month was 744,592, or 218 gallons per house, and 27-9 gallons per head of the population. In October, 1887, the number of houses supplied was 731,508; and the quantity of water allowed for each person 27-9 gallons. Of the entire bulk of water supplied last month, 80,490,057 gallons were drawn from the Thames, and 81,504,831 gallons from the Lea and other sources.

In his report to the Registrar-General on the quality of the Metropolitan water supply last month, Dr. E. Frankland makes the following remarks:—"Taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health, was; Kent, Colne Valley, and Tottenham, 0-8; New River, 0-9; Southwark, 1-6; Chelsea, 1-8; Grand Junction and Lambeth, 1-9; West Middlesex, 2; East London, 2-1. The proportion of organic matter present in the Thames water supplied by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies was, as in the previous month, exceptionally small for river water. All the samples were clear and bright. The water principally derived from the Lea, and distributed by the New River and East London Companies, also contained only a small proportion of organic matter; the amount present in the New River Company's supply being less than in any of the other river waters. Both waters were clear and bright. The deep-well waters of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health contained, as usual, only a very small proportion of organic matter; and the Colne Valley Company, by softening their supply with lime before delivery, thereby rendered it also of excellent quality for washing and all other domestic purposes."

In the course of their report to the Official Water Examiner for the Metropolis (General A. De Courey Scott, R.A.), on the composition and quality of the daily samples of water supplied to London last month, Messrs. Crookes, Odling, and Tidy say: "The high quality of the water referred to in September's report [see ante, p. 732] has been well maintained during the past month. Moreover, the analyses of the daily samples are marked by great uniformity of excellence. Thus, of the Thames-derived waters, only 4 out of 130 samples examined by the oxygen process required more than 0-045 grain of oxygen per gallon to oxidize the organic matter; the average of the whole 130 samples being a little over 0-03 grain per gallon. Of the 189 samples examined, 187 were clear, bright, and well filtered."

PROPOSED ELECTRIC LIGHTING SCHEME FOR PADDINGTON.—The Paddington Vestry have resolved to obtain plans and specifications to enable them to proceed with an application to Parliament for a Licence to supply the electric light for public and private purposes throughout the parish.

THE BURSTING OF A WATER RESERVOIR NEAR GENEVA.—It is reported that the accident at Montreux, to which reference was made in the JOURNAL last week, was due to the telephone. The reservoir (which furnished the motive power of the Chillon electric tramway) being so full as to cause apprehensions, the man in charge was telephoned to in the words, "Ne mettez plus d'eau"—i.e., "Put no more water." He did not catch the first two words, and consequently turned on more water; the result being that the reservoir burst, with loss of life and great damage to property. Perfect security, however, now prevails.

LAMBETH WATER-WORKS COMPANY.

THE HALF-YEARLY REPORT OF THE DIRECTORS.

The report of the Directors of this Company for the six months ending Sept. 30, 1888, which will be presented at the half-yearly general meeting of proprietors on the 27th inst., states that, notwithstanding a falling off in the charges for road-watering supplies by meter (mainly attributable to the past wet season), and for water for use in building operations to the extent of £617, there has been an increase of £1397 15s. in the water-rents, &c., as compared with the corresponding period of last year. On the other hand, although the item of storage, in consequence of the repairs to one of the Molesey reservoirs, is £639 more, and the payments to the Thames Conservancy and for rates and taxes are increased by £250 and £329 respectively, the total expenditure is £61 less than in the summer months of 1887. During the six months reported upon, 1122 houses and other supplies of water, estimated to afford an annual water-rental of £2813 10s., were connected with the Company's works; as against 1154 houses, yielding a rental of £3084, in the six summer months of 1887. There was expended on capital account during the half year ending in September, £6934 19s. 8d.; making, since the passing of the Metropolitan Water Act, 1871, a total outlay of £730,177 13s. 11d. on new works. The surplus transferred from the revenue account to the dividend and interest account is £69,197 15s. 11d. After payment of interest on debenture stock, there is to the credit of the latter account an available sum of £68,869 16s. 10d., out of which the Directors recommend the distribution of the maximum dividend, at the rate of 7½ per cent. per annum on the shares issued under the Company's Act of 1856, and a dividend at the rate of 9 per cent. per annum on all the other share capital of the Company (less income-tax). These dividends will, it is estimated, amount to £62,203; and consequently a balance of £6666 will remain to be carried forward, as against £5916 last year. Constant supply is now given to 44,769 houses, &c., in all of which the Board of Trade regulations as to fittings have been complied with. The whole of these houses are regularly inspected by the Company's officers; and the Directors express satisfaction at finding that while the supply has remained constant, without any interruption, in all the divisions of the district, there has been no increase in the consumption of water as compared with the intermittent system. They are about to make some experiments in Wimbledon, with the view of giving constant service to all the houses supplied by the Company in that parish. Under the Lambeth Water-Works Act, 1886, all debenture stock authorized by that Act to be created must be issued under auction clauses, and at the end of three years after such issue a certain sum must be set aside out of the profits, in addition to the interest on the stock itself, for purchasing and extinguishing the share capital of the Company. As the time is approaching when it may become necessary to raise some of this debenture capital, the Directors desire to obtain the sanction of the proprietors to create and issue, by auction or tender, the £150,000 of debenture stock authorized by the above-named Act, with 4 per cent. interest.

THE USE OF OIL FOR PUBLIC LIGHTING AT NEW SOUTHGATE.—A correspondent of a local paper complains bitterly of the inefficient lighting of New Southgate by oil. He says: "Some two years ago the Friern Barnet Local Board professed to light up this neighbourhood; and it has proved a total failure. There is scarcely a night passes that one-half of the oil-lamps are not blown out, and those that are alight only serve to make the darkness more visible. I suppose we have the very worst lamps for street lighting that can be found."

CHELTSEY GAS COMPANY.—The annual general meeting of this Company was held last Thursday—Mr. J. Bartholomew in the chair. The Secretary (Mr. J. Moir) read the report of the Directors, which showed that the profit would allow of the declaration of an additional ½ per cent. dividend, to which the shareholders were entitled owing to the price of gas having been reduced 2d. per 1000 cubic feet. The excellent results of the past year's working have influenced the Directors to again lower the price as from the 1st ult.; thus benefiting both consumers and shareholders. The increased consumption of gas will, it is thought, necessitate the erection of another holder in the spring of next year. The Chairman, in moving the adoption of the report, said there was much cause for congratulation at the continued success of the undertaking. The motion was carried, and the dividend declared. After payment thereof, and debiting the insurance account with £119 in addition to that of last year, there will be left a balance of £1188. The retiring Directors and Auditor having been re-elected, a unanimous vote of thanks was accorded to the Manager and Secretary for their exertions on behalf of the Company. A similar compliment to the Chairman and Directors closed the proceedings.

GARFORTH WATER SUPPLY.—Last Wednesday, Mr. A. Taylor, one of the Local Government Board Inspectors, held an inquiry at Garforth, with reference to an application of the Tadcaster Rural Sanitary Authority, whose district includes Garforth, for authority to borrow £3000 to enable Garforth to procure a supply of water from the Corporation of Leeds. Hitherto Garforth, whose population numbers about 2300, has drawn its water from wells, tanks, and pumps, all of which, from one cause or another, are regarded as unsatisfactory. The total outlay of about £3000, for which water could be conveyed from Leeds, can be met by a rate of 7d. or 8d. in the pound upon the property in Garforth, and about one-fourth of this amount upon land. It is thought, however, that in the course of time the receipts from water-rents will make the scheme self-supporting. In support of the application, Dr. Wilson, the Medical Officer of Health for the district, produced several analyses of the water now being used by the people, which were not calculated to induce those who are alive to the importance of pure water to rest content with existing arrangements. In opposition to the scheme, it was contended that there is plenty of water in Garforth at present, and that more can be obtained by sinking additional wells. The matter now awaits the Inspector's report.

HEYWOOD GAS AND WATER WORKS.—A special meeting of the Heywood Town Council was held last Thursday, to determine upon the expediency of promoting next session a Bill to extend the time for the construction of the Ashworth Moor reservoir and other works, to provide for the compulsory purchase of the gas and water annuities issued under their local Acts. The Town Clerk stated that by the Act of 1877 the Local Board obtained power to construct a reservoir and works at Ashworth Moor. By that Act they had to purchase the land and other easements in five years from its passing, and by another section the works were to be constructed within 12 years. The Corporation, as successors to the Board, purchased the land and easements within the period named, but had not constructed the works. Last year they determined to apply for power to extend the time for their construction by Provisional Order; but the Local Government Board had not power to grant the Order. The Council were consequently driven to the last year; and the only way to get an extension of time was to apply to Parliament. This was the main object of the Bill. He explained the nature of the application in regard to the annuities, and said another matter was the borrowing of money for water and other purposes—principally water; the amount to be determined hereafter. The necessary resolution was passed.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

The strike at the Leith Gas-Works in one sense still continues—the men who struck are still out; but, in another sense, it may be said to be at an end, because the Commissioners have advanced the wages paid in the works to practically the figure asked by the men. It is difficult to withhold sympathy from the men. They were lured into making the demand which they did; and when it was refused, they struck. No sooner had they gone out, than the Commissioners conceded sufficient to satisfy them; but stipulated, in offering the increase, that they would only take on the men they wanted. This was announced to the men on Monday; and along with the announcement, there was published a prominent advertisement offering the increased wages for men to work in the Leith works. A meeting of the men on strike was held on Monday, at which it was resolved that “no man start work unless he be put on the same footing as the Edinburgh men, and every man reinstated to the position he held before the strike.” This resolution was reported to the Assistant Manager at the works, who undertook to lay it before his superiors. Next day some of the men presented themselves at the works, apparently in violation of the above resolution, but were told that their places were filled up, and that, if they were wanted, they would be sent for. This implied that a full staff had been secured; and the only hope of the men who are out lies in the expectation that the new men, being for the most part unacquainted with the work, will soon be found to be unfit, and that the old hands will then be called in. In this they were strengthened by statements that retort-lid explosions were frequent, doing damage to plant; and they concluded that the Manager would soon find it to be unprofitable to keep on the new hands. I confess I am not so sanguine as the men. Their places have been filled up; and the Commissioners have taken the precaution, in order to avert the probability of future difficulties, to require the new hands to sign articles for one month. This, for one thing, prevents the new men being dismissed in order to make room for the old. Then the Commissioners have strengthened their position by conceding to the pipelayers and outdoor labourers terms which place them practically on a level with their brethren in Edinburgh, and by similarly treating the mechanics inside the works, in whose case the working week has been reduced from 56 to 51 hours without any decreased rate of pay. By this means, disaffection will be prevented from spreading; and whether or not the works can be carried on to the same profit or with the same convenience, the Commissioners are committed, and cannot go back. It does seem hard that the men who have forced this improvement should not take any benefit by it; but, on the other hand, there is a good deal to be said for the position taken up by the Commissioners. The origin of the strike must be laid on the shoulders of the “garrulous minority” of the Board. The value of these electioneering speeches is to be seen in this, that not one of the speakers has taken a single public step to support the men. But the men took their remarks in earnest, and attempted to force the Commissioners to a concession—a very foolish step, when it is remembered that the Commissioners had remitted the whole question of wages to a Committee to consider. Had the men been well advised, they would have waited for the report of that Committee; and they would probably have received what they asked for. It is a curious medley of rights and wrongs, in which both sides must bear a certain amount of blame, and probably neither will have any advantage. The men, as a body, have lost their employment; while the Commissioners have secured a staff of men who, for some time, cannot be expected to do their work so well. I understand the Commissioners take the view that, if they are to pay the increased wages, they must have a superior class of men to those who were content to work at the lower rate. In ordinary circumstances, this might have been accepted. As it is, I am afraid it can only be regarded as a species of salve to their conscience—an excuse to be put before the public, and which may go down with them, but which will not receive much credence at the hands of all who exercise their reflecting faculties.

The first meeting after the elections of the Arbroath Gas Corporation was held on Monday. I suppose Provost Anderson has found it awkward to have to deal with opposition both in Committee and at the public meetings of the Board; and the Committee of Management which he proposed to appoint did not, as formerly, include all the members of the Corporation, but only two-thirds of them. He had endeavoured, he said, to select representative gentlemen on both sides of the question which at present chiefly occupies their attention. His efforts in that direction did not please Mr. Michie and Mr. Sandemson, both of whom are opposed to the extension of the gas-works. These gentlemen moved that the whole Board be appointed, as before; but only themselves voted in support of it. The Provost's list was thus adopted; and, whether he intended it or not, he has succeeded in excluding the chief members of the opposition from the Committee. Henceforth the movers in the new scheme will not require to reveal their hand to the opposition before playing.

A furious gale has been raging in Scotland for the past two days, doing great damage to property. At Cowdenbeath, in Fife-shire, the newly-erected oil-gas works have been completely wrecked by the fall of the chimney of the works. The stack, about 40 feet high, went crashing through the roof of the works, and smashed the retorts and fittings. Meantime the gas supply has been stopped. It is proposed to re-construct the works on a more extensive scale. In Edinburgh an old feature has been intensified by the storm. About ten years ago Lord Provost Falshaw announced, at a public meeting, that nearly one-third of the public lamps required to be renewed annually, on account of the destructive force of the wind experienced in the city. It is reported to-day that 54 lamps were destroyed by the fury of the gale during last night, and that the previous night the number which collapsed was nearly 40—making about 90 in all. Another effect of the severe weather has been the giving way of a bank owing to the heavy rains, by which about 15 feet of the main pipe supplying water to a portion of the town of Alyth were displaced, and the water supply was stopped.

By the opening of the Forth Bridge, the town of Queensferry, at present a veritable “Sleepy Hollow,” will have a chance of improving its position. Success in this will depend on local effort; and it is satisfactory to note that the Police Commissioners are taking “time by the forelock,” and endeavouring to have matters tidied up before the influx of expected settlers. Besides looking into sanitary affairs, an extensive scheme of water supply is all but arranged for; and now, in addition, the question of assuming the control of the gas supply has been hinted at. The matter came before the Commissioners on Monday, when Mr. C. Carlow, the Gas Manager, wrote stating that the rates for street lighting charged by the Gas Company were quite inadequate, and asking that they be increased. At present 12s. 6d. is paid for lamps which are extinguished at 10 o'clock, and 17s. 6d. for lamps which are alight all night. On the motion of the Provost, it was agreed to raise the rate by 2s. 6d. per lamp, if the ten o'clock lamps be kept burning on Saturday night till eleven o'clock. Some of the members urged that the Commissioners should themselves supply the gas—a proposal not very well defined, but which, in a small town like

Queensferry, could only mean the acquisition of the Company's property. The matter was not taken up; but it may be heard of again.

The town of Buckie was recently created a burgh; several villages being incorporated in the process. One of the advantages to the local Gas Company of municipal government has already emerged, in a communication from the Police Commissioners, which was laid before the Easter Buckie Gas Company on Friday of last week, requesting them to extend their mains to the two villages of Gordonsburgh and Janstown, the streets of which the Commissioners propose to light. The Directors of the Company resolved to accede to the request, doubtless in the expectation of being able to secure a large increase of customers among the residents.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

The vexed question of the public lighting of the district of Craignenk, which is part of the burgh of Wishaw, again came before the Police Commissioners of that town at a special meeting held last Monday. The Committee previously appointed for the purpose of making the necessary inquiries regarding the matter, reported that, of the house proprietors written to, only six had replied; and of them, only three had agreed to connect their properties with the gas-mains that might be laid for the street lighting. Certain recommendations were made by the Committee as to the laying of the mains, which would have a total length of about two miles; the cost, as estimated by Mr. McNair, the Gas Manager, being about £668. A somewhat keen discussion took place on the matter; but eventually the recommendations of the Committee were adopted.

The lighting of the common stairs within the Burgh of Rothesay seems to be in a most unsatisfactory state, judging by the remarks made at the monthly meeting of the Town Council on Monday last. Mr. MacKinnon inquired what steps had been taken to put the regulations in force regarding the lighting of these stairs. Provost Thompson replied that the matter was being dealt with by the Superintendent of Police, by whom a list of stairs still unlit had been made up, which would shortly be brought before the Lighting Committee. He proceeded to say that the question of lighting the stairs was before the Committee last year; but that, as there was a probability of the new Police Bill for Scotland becoming law this session, it was thought better to try and work on for another year, as they had been doing. The Bill referred to proposed to give power to charge the lighting of the common stairs to the owners of dwelling-houses; and eventually the whole arrangements for lighting would be in the hands of the Burgh.

Regarding the street lighting of the Royal Burgh of Rothesay, a Scotch-American, now temporarily resident in the town, attempts, in a letter to one of the local papers, to throw some “light” on the subject. Being a great admirer of Rothesay, he thinks it might get on much faster and better if it had more of the “go-aheadism” of the Americans; and he enthusiastically suggests that the beauty of the lovely crescent bay (a miniature Bay of Naples) and its sloping hillsides would be much increased if they were lighted with the brilliant electric light instead of a dingy (?) gas. Not only, he remarks, is every first and second rate town in the States illuminated in this way, but many twentieth and thirtieth rate towns are so lighted. Great Falls (which is the nearest town to his own sheep farm in Montana) is, he says, a place of only 1500 inhabitants; and yet it has been lighted by electricity for years. He speaks of the difficulties which the Electric Lighting Act is said to place in the way of the general adoption of the electric light in British cities and towns; but it is evident that he does not know all the facts of the case, one of the most important of which is the very low price at which coal gas can be supplied compared with the cost of the electric light. This letter affords the Editor a text for some remarks, which he concludes in these words: “Now that the embargo foolishly placed by Parliament on the adoption of the electric light is about to be removed, all enterprising towns will, no doubt, be setting about its adoption. There is in Rothesay a water power wasting into the sea from Loch Fad more than sufficient to develop electricity enough to light all the dwellings and streets of the town; and it would be a feather in our cap if we should manage to be the first town in Scotland to adopt this great improvement in lighting.” The writer does not seem to be aware of the effort made by the municipal authorities of Greenock within the past three years or so to turn electricity to account for lighting the public streets—an effort which proved decidedly unsuccessful, even though an excellent supply of water power was used, which was obtained almost without any expense.

At a meeting of the Ardsrossan Police Commissioners held last Monday, it was agreed to adopt the recommendation of the Gas Committee to accept an offer by Messrs. Laidlaw, Sons, and Caine, of Glasgow, amounting to £2124, for some important extensions and alterations to be made at the gas-works.

Towards the end of last week, the important mining village of Dreg-horn, near Kilmarlock, had its streets lighted with gas for the first time, amidst great rejoicing from the people generally. The village has made great progress in public improvements within recent years; one of them being the introduction of gas into the dwelling-houses, which took place about ten years ago.

The shares of the Partick, Hillhead, and Maryhill Gas Company were in demand on the Glasgow Stock Exchange last Tuesday at 80s. per share; but sellers held out for 82s. 6d., and no business was done. They changed hands on Friday at 80s. per share; and at the close of the market buyers were offering 77s. 6d.

Yesterday's pig-iron market closed with Scotch warrants at 41s. 2d. cash, buyers; Cleveland, at 33s. 8d.; and hematite iron, at 43s. 11d.

Quietness has been the rule in the coal trade this week; but prices remain firm all round. The wages of the miners are now being generally advanced where the increase had not previously been conceded.

CHECKING WASTE OF WATER AT SHREWSBURY.—At the meeting of the Shrewsbury Town Council on the 9th inst., the Borough Surveyor and Water Engineer (Mr. W. Chapple Eddowes) presented a report, in the course of which he gave the results of the adoption of the Deacon meter in certain districts of the city. When the supply was intermittent, the average consumption before the inspection of the fittings was 81,450 gallons in 12 hours, or 27.15 gallons per head. After the first inspection and repair, it was 57,450 gallons, or 19 gallons per head; and after the second inspection and repair, 51,450 gallons, or 17.15 gallons per head. The total saving was 30,000 gallons, equal to 10 gallons per head per day. When the service was constant, the average consumption per day before the inspection of the fittings was 146,641 gallons; after the first inspection and repair, it was reduced to 98,641 gallons; after the second inspection and repair, to 86,641 gallons—the consumption per head being 48.88, 32.88, and 28.88 gallons. The total saving effected was 60,000 gallons, or equal to 20 gallons per head per day. The constant supply was, therefore, reduced almost to what the intermittent supply was prior to the repairs. The detection of the waste had been effected solely by the meters.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Nov. 17.

Sulphate of Ammonia.—The market is again stronger, due to the further progress of the upward movement in nitrate; but it will be noticed that sulphate values do not by any means advance in the same ratio as nitrate prices, the rapid inflation of which is already making consumers dubious about their ultimate maintenance. On spot, nitrate has been put up, within a week's time, nearly £1 per ton (to 11s. 6d. per cwt.), which indicates a rise of about £2 10s. per ton since the beginning of September. It would be very difficult to find sufficient arguments for this rise, as even any statements on paper cannot show that there will be a famine in the spring; nor is there any reason why spot values should be advanced to an absurd level, when there is no agricultural demand, nor will there be for months to come. It is said that stocks are low in the United Kingdom. But there is very little wanted for present delivery; and it may serve holders, here for instance, to dole out their 4000 to 5000 tons stocks—they could not sell much if they would. Cargoes, Oct.-Nov. sailing are now quoted at 11s. 6d. (the spot price). Nitrate can be bought readily at 11s. 3d. from second hands; and indeed these re-sales, showing in many cases handsome profits, may eventually play havoc with the market. From this cursory glance at the nitrate market, those interested in sulphate can form their own opinions. Attention will have to be given to the fact that sulphate has barely advanced £1 per ton since September; and it will be noticed that the difference in the respective values of the two commodities is only about £1 per ton. This difference ought to be increased, one way or the other, to place the respective articles on their proper basis, or we may see them again on an equality, as they have been for two successive springs (1886 and 1887), and the autumn of 1885. The sulphate quotations at the close stand at £12 5s. (buyers), £12 7s. 6d. to £12 10s. (sellers) f.o.b. Hull; Leith and Liverpool about 2s. 6d. less.

LONDON, Nov. 17.

Tar Products.—With the exception of pitch, which is quoted a little higher, all the products continue at about the same value as last week. Considerable activity exists, and stocks are undoubtedly low. The following prices have ruled during the week:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 3s. 2d. per gallon; 50 per cent., 2s. 6d. Toluol, 1s. 7d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 1d. per gallon. Light oil, 3d. per gallon. Creosote, 2d. per gallon. Pitch, 17s. to 20s. per ton. Carbolic acid (crude), 8s. 9d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 5d. per unit; "B," 1s. 3d. **Ammonia Products.**—Sulphate, if anything, is a little quieter; but buyers are, all the same, willing to book forward business at an advance on to-day's value. Considerable shipments are being made; and stocks are low. The selling price during the week has ranged between £12 2s. 6d. and £12 5s. per ton. Prices of other products are about—Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £25. Sal-ammoniac, £30 per ton.

[From the *Chemical Trade Journal*, Nov. 17.]

Sulphate of Ammonia.—From some quarters the market has been reported quieter; but the fact remains that £12 5s. was paid at Hull on Monday last for prompt delivery. It is quite true that the market to-day is not as earnest as it was a week ago, but that is in a measure due to a fearfulness that prices might run away under small stocks and a good demand, if too strong a desire for purchase was now expressed. It is now understood that many users are fearful of a scarcity in the spring and consequent high prices, and that it may not be possible to purchase when it is required if a mild winter intervenes and early spring planting is possible. Beckett and outside London makes stand at £12 5s., and Leith £12 3s. 9d. per ton.

Tar Products.—Benzoles are a little firmer; and sales have just been made over the remainder of this year at prices showing an advance on that quoted last week. At these prices also it is rumoured that some business has been done for next year. For 90's benzol, the prices ruling to-day may fairly be stated as 3s. 2d. to 3s. 3d.; while 50/90's are fetching 2s. 6d. to 2s. 7d. All other products remain much the same as in our last report. Anthracene is firm at 1s. 3d. for "B" quality, and 1s. 5d. for "A," on the basis of 30 per cent. Pitch is now a fairly good market, and seems likely to be so during the whole of the winter.

THE SWANSEA CORPORATION AND ELECTRIC LIGHTING.—At the meeting of the Swansea Town Council last Wednesday, Mr. Martin moved the adoption of the minutes of the Special Gas Committee, which stated that the Surveyor had reported the result of his visits to various places where public and private lighting is effected by electricity; and, in accordance with his suggestions, it was recommended that tenders be invited for the lighting of a portion of the borough (which was defined). He said the present cost of lighting this area was £539 13s. 8d. per annum; and the Surveyor estimated that to light it with electricity would cost an additional £175 per annum, or 30 per cent. more, while the total increase in illuminating power would be raised from 3288 to 44,400 candles. The Surveyor was directed to supply each member of the Committee with a plan showing the proposed position of the electric lamps in the area referred to. It was decided to invite tenders for lighting by electricity the streets specified. The cost, he said, would be certainly greater; but there would be a considerable increase in illuminating power. On this ground alone he had no doubt the town would be glad to have the alteration. The minutes were adopted.

DISPUTED METER REGISTRATION.—At the Sale Petty Sessions on Monday last week, Mr. J. Richardson, Solicitor, of Sale, appeared in answer to an adjourned summons, taken out by the Shelford Gas Company, for the non-payment of £4 18s. 4d. on account of gas supplied to him. He admitted liability to the extent of £1 12s.; and this amount he had paid into Court. The matter really in dispute was the accuracy of the registration of the defendant's meter, which was one that had been on view at the Manchester Exhibition. The meter had been tested on two occasions—once for the Company and once for the defendant—and had been found correct. Mr. Richardson maintained that the charge was excessive. He said the average for the past 20 years had been about £1 11s. 6d. for the half year; and this fact he considered to be of more value, as evidence, than the indication of a meter. It was contended, on behalf of the Company, that, under the Gas-Works Clauses Act, the meter index is to be taken as *prima facie* evidence of the quantity of gas consumed; and as the meter had been tested and found to be correct, they were entitled to be paid for the gas shown to have been passed through it. In the result, the Bench decided that the amount paid into Court was sufficient discharge of the claim, inasmuch as the Company's meter inspector had noticed the unusually large consumption for the period in question, and had remarked that there must be something wrong. They also allowed defendant his costs.

PADIHAM WATER SUPPLY.—Last Saturday week, an extraordinary meeting of the Padiham and Hapton Local Board was held, to consider the propriety of promoting next session a Bill to extend the time for the completion of the water-works authorized by the Padiham Local Board Act, 1882; to construct a compensation reservoir, and other works in connection with the water undertaking of the Board; to enable the Board to borrow further capital for the above purposes; to extend the district so as to include in the present gas and water limits of the Board the rest of the township of Padiham (not included in the Board's district), and part of the extra-parochial township of Ightenhill Park. Mr. Ingham proposed a resolution couched in the terms of the notice. Mr. Monk, in seconding, said they asked Burnley to supply them; but Burnley would not listen to them. If they could have bought water cheap enough, they would not have gone in for works of their own. They found, however, they could not do better than start a scheme; and they entered into a proposed expenditure of about £45,000, but it might run up to very near £80,000. The resolution was agreed to.

PONTEFRAC TOWN WATER SUPPLY.—On Wednesday, the 7th inst., Major-General C. Phipps Carey, R.E., held an inquiry, on behalf of the Local Government Board, with reference to an application of the Pontefract Town Council to borrow £23,152 for works of water supply. There was a large attendance of the ratepayers of the borough—many in favour, and others against, the water scheme, which proposed to bring a supply from Roall, near Selby. The Inspector made detailed notes of the whole scheme, which has the support of the Mayor, and many members of the Council, and which, if carried out, is intended to supply Knottingley and other places on the way. It was pointed out that at Knottingley the inhabitants are in many parts drinking water taken from the River Aire, and within a short distance of the outfall of sewage into the river. One speaker held that the Roall water was suitable for all manufacturing purposes; the towns of Birmingham, Nottingham, Leicester, and other places being supplied from the red sandstone. Others spoke strongly against the Roall scheme; and held that the water at present used is good, as proved by the death-rate, and that only an auxiliary supply is needed. The opponents of the scheme prayed that the Inspector would recommend to the Local Government Board that it should be postponed, in order that other districts might be surveyed, with the view of obtaining an additional supply only. At the close of the inquiry, the Inspector said, from the evidence he had heard, a better supply of water was needed; and he would report the matter at once, so as to have the question settled. He then visited the wells and the surrounding district.

THE TUNBRIDGE LOCAL BOARD AND THE WATER-WORKS.—A Committee of the Tunbridge Local Board recommend that body to purchase the works from the Water Company for the sum of £30,000.

PROPOSED LIGHTING OF ABBEY WOOD BY OIL.—The Plumstead Board of Works have decided to light the district of Abbey Wood by oil instead of gas, providing they can effect an agreement with the Erith contractors on the same terms as those in existence there.

MONTE VIDEO WATER COMPANY.—From an available balance of £31,901, the Directors of the Monte Video Water Company, Limited, in their annual report, propose a dividend of 5 per cent., and an addition of £12,000 to the special reserve fund; carrying forward £2391.

THE AUXILIARY WATER SUPPLY TO LIVERPOOL.—At the meeting of the Water Committee of the St. Helens Corporation on Wednesday last, the Deputy Town Clerk reported that on the previous Monday he received an intimation from the Liverpool Corporation to discontinue the auxiliary supply of water furnished by them for the past few months.

PROPOSED FURTHER REDUCTION IN THE PRICE OF GAS AT ROCHDALE.—It is reported that the Rochdale Corporation Gas Committee will consider, at a meeting to be held to-morrow, the suggested further reduction in the price of gas. It is said the members of the Gas Committee are unanimous in favour of a reduction; but undecided as to the extent to which the charge should be decreased.

NEW JOINT STOCK GAS AND WATER COMPANIES.—The Market Rasen New Lighting Company, Limited, was registered on the 2nd inst., with a capital of 4500 shares, of £10 each, to acquire the undertaking of the Market Rasen Gas Company, and to carry on the business.—The Pocklington Water Company, Limited, with a capital of £3000, in £5 shares, has been formed to supply the town of Pocklington, in the East Riding of Yorkshire, and the adjoining and neighbouring parishes and districts, with pure spring water; and generally to carry on the business of a water company.—The Coal and Coke Fuel Company, Limited, has been formed with a capital of £30,000, in shares of £10 each, to acquire the exclusive right to use, sell, and deal with certain inventions known as "Improvements in the manufacture of fuel from coal slack and similar substances, and in the distillation of coal tar and similar substances."

ALEXANDRIA WATER COMPANY.—The Directors of the Alexandria Water Company have declared a dividend of 2½ per cent. for the half year ending Sept. 30.

REDUCTION IN PRICE.—The Directors of the Chichester Gas Company announce that after the 1st of January next the price of gas will be 4s. 3d. per 1000 cubic feet; being a reduction of 3d. per 1000 feet.

MONTE VIDEO GAS COMPANY, LIMITED.—The Directors of this Company have declared an interim dividend of 12s. per share, free of income-tax, in respect of the half year ended June 30 last; being at the rate of 6 per cent. per annum.

ELECTRIC LIGHTING AT BARNET.—A correspondent sends to the *Barnet Press* the following figures as to the comparative cost of gas and electric lighting in that town:—Electric light: 74 lamps at £5 8s. = £399 12s. Gas: 100 ordinary lamps at £2 18s.; two lamps at £16; and two at £10 = £342. He gives them to show that the contractor has not succeeded in "replacing gas by electricity at a similar cost," which, he says, he undertook to do.

THE PRICE OF GAS AT KNARESBOROUGH.—The Knaresborough Gas-Works were purchased for £2000 by the Improvement Commissioners in the year 1846 from the late Mr. John Malam, of Hull. On the Commissioners becoming owners of the works, the price of gas to private consumers was reduced from 10s. to 8s. 4d. per 1000 cubic feet; in the year 1850, to 7s. 6d.; in 1853, to 5s. 10d.; in 1855, to 5s.; afterwards to 4s. 2d. and 3s. 4d.; the present price being 2s. 6d. The Manager (Mr. W. Stansfield) reports that during the last half year there was an increase of 653,200 cubic feet in the sale of gas.

THE USE OF THE DIVINING-ROD AT HASTINGS.—The Hastings Board of Guardians have decided to proceed to a practical test of the recommendations of Mr. Mullens, the "diviner," whose experiments with the divining rod in searching for water on the site of the new workhouse a couple of months ago caused considerable interest not only in that town, but throughout the country, and were recorded in the *JOURNAL*. For this purpose they have accepted a tender of about £1000 for the sinking of a well and the making of headings, in accordance with the plan mapped out by Mr. Mullens.

GWYNNE & CO., ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C. GWYNNE & BEALE'S PATENT GAS EXHAUSTERS & ENGINES.

Telegrams: "GWYNNEGRAM, LONDON." Telephone No. 2698.

Exhausters of nearly all sizes in Stock.

Prize Medals at all the Great International Exhibitions.

Exhausters equal to a total capacity of more than 26,000,000

cubic feet passed per hour have been supplied by us.

Our new Patent Non-Fluctuating Exhausters, to work without the slightest oscillation or variation in pressure, are strongly recommended.

MAKERS OF EVERY DESCRIPTION OF HYDRAULIC AND GAS MACHINERY.

Gwynne & Co.'s New Catalogue and List of Testimonials can now be obtained on application.

Exhausters and Vertical Engine as supplied for both the Fulham and Bromley-by-Bow Stations of The Gaslight and Coke Company.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

JOHN RILEY & SONS, Chemical Manufacturers, Hapton, near Acerrington, are MAKERS of SULPHURIC ACID, from Brimstone, for Sulphate of Ammonia making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitrol. References given to Gas Companies.

LOUGHBOROUGH GAS COMPANY.

WANTED, at once, an Experienced MAN, who can lay Service-Pipes, Read and Fix Meters, and willing to make himself generally useful. Reply, stating age, wages expected, &c., to the MANAGER of the Gas-Works, LOUGHBOROUGH.

COLLECTOR WANTED.

THE Directors of the Hornsey Gas Company invite APPLICATIONS for the COLLECTORSHIP of one of the Divisions of their District. The Collector would be required to find Security to the amount of £250.

Applications, with testimonials, to be forwarded, sealed up, on or before the 23rd inst., to the SECRETARY, 63, CHANCERY LANE, W.C.

OXIDE OF IRON.

O'NEILL'S Oxide has a larger annual sale in the United Kingdom than all other Oxides combined. Purity and uniformity of quality guaranteed. Pamphlet, "How to Purchase Bog Ore," to be obtained on application.

Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C. JOHN WM. O'NEILL, Managing Director.

ANDREW STEPHENSON, Agent for the GAS PURIFICATION AND CHEMICAL COMPANY, Limited, Palmerston Buildings, Old Broad Street, LONDON, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 30, ST. ANDREW SQUARE, EDINBURGH, | SCOTLAND. No. 54, BERNARD STREET, LEITH.

ADVERTISER seeks Engagement as WORKS MANAGER and CHEMIST of Tar, Gas, or similar Works.

For particulars apply to No. 1659, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WANTED, by a Young Man, a Re-engagement as FITTER in Gas Works. Well used to Heating and Cooking Stoves, Meter Fixing, and Meter Reading, Service Laying, and House-fitting work. Address FITTER, 5, Collingwood Road, WALTHAMSTOW, E.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE & Co, 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56,

MILBANK STREET, LONDON, S.W.

[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.

* * See Advertisement on Page III. of the Wrapper of this week's issue.

W. C. HOLMES & Co., Huddersfield,

ANN 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings. * * See Advertisement p. 863 of last week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas- Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham.

Analysis of Coal, Oxide, and all Gas Materials.

WANTED, a Situation as Fitter; used to Fixing Lead or Iron Piping, putting in Mains and Services, Fixing Meters, Repairing, Glazing, and Painting Lamps; willing to be useful about the works. Address JOHN KERR, 60, Counce Street, Blackpool, LANCASHIRE.

prevailing system should be abandoned in favour of some other course which they recommend on their own authority, such as it is, without proving its acceptability. The world is not to be moved in this way; but a few hare-brained folk may be disturbed. We have no respect for an "F.R.S. Ed.," without figures, in connection with a matter of which figures are the very essence. Mr. Thomson must either go further and prove his case, or rest under the imputation of having published a mass of mere babble.

MR. W. MOONEY ON GASHOLDER GUIDING.

IN another column will be found the second part of Mr. W. Mooney's contribution to the *American Gaslight Journal* respecting the question of gasholder framing. The first part of Mr. Mooney's article, which we reproduced some weeks ago, consisted of a review of the various suggestions that have been offered on this subject in the columns of the JOURNAL and before The Gas Institute. It seemed serviceable to bring these points together; and therefore we reprinted Mr. Mooney's citations, correcting them by reference to the text, as they had (as the author now acknowledges) been hastily put together during a busy season. We supposed that the author intended to use this mass of material as the foundation for some useful suggestion of his own; and consequently awaited with some interest the continuation of his article. Unfortunately, it cannot be said that Mr. Mooney has much advanced the question by his treatment of it. Attentive perusal of the second portion of his communication, in which any originality of suggestion or acuteness of criticism would be looked for, reveals nothing but the most superficial observations, not particularly well expressed. Thus, when he states in his third paragraph that "the point at which the holder would buckle or break in Mr. Webber's holder would be on the leeward side," he seems to imply that buckling and breaking are synonymous, whereas in point of fact the buckling would be on the leeward side, and the breaking (*i.e.*, tearing of the sheets) would be on the opposite or windward side of the supposed holder. Mr. Mooney's remarks in the same and following paragraph upon Mr. Gadd's system, and the advantages of tangential rollers, are not at all impressive; and, whatever he may think, English engineers are not in the habit of discussing points of gasholder construction in vulgar slang, nor do they consider such language conclusive. The single constructive contribution which Mr. Mooney brings to the discussion is a revival of Joshua Horton's proposal, patented in 1851, to fix guide cantilevers upon the grips of the lower lifts of a telescopic holder instead of erecting them upon the ground. This is the plan that has been recorded as tried without success at the Pigott Street (Blackfriars) gasholder station. There is no advantage in it; for if we must have guide-columns, these may as well be erected on the ground as carried upon the grips of the holder. Mr. Mooney is evidently unable to grapple with the problem of guiding a holder from the base, or he would not ask such a question as this: "Why will not a holder depending on single rollers at the bottom have a greater tendency to bind than one having two or more series of rollers?" How can a single tier of rollers possibly "bind"? Then, again, what does Mr. Mooney mean by stating that dispensing with the girders connecting the tops of the guide-columns is the first step in the direction of dispensing with guide-framing, and especially that it is a step which can be easily and safely taken, in order to save "6 per cent. of the whole weight of iron in a double-lift holder?" Did he never hear of guide-columns actually snapped off near the base by their own vibration in the wind during erection, and before their tops could be steadied by the connecting girders? He is leading the gas manager straight to disaster with this suggestion. It is quite clear, as we have already observed, that Mr. Mooney has no grip of the question which he professes to discuss. It is thus not worth while to follow him in his remarks upon the housing of gasholders, which is essentially a question of climate. It is very funny, however, to read "that there is no limit, within reasonable bounds, to the size of a holder that might be covered." After noticing this fine specimen of an American breed of the genuine old Irish bull, we have only to add that, as Mr. Mooney was doubtless actuated by the desire to be useful to gas managers in thus entering into the public discussion of an admittedly difficult and interesting subject, it is to be regretted that he did not make himself a little more sure of his ground before offering criticism and advice, to which the objection distinctly applies that "where true it is not new, and where new it is not true." He means well; but must be taken with caution.

Water and Sanitary Affairs.

WHAT is everyone's business is, in the general way, no one's business; and, therefore, in the matter of the continued pollution of the Thames, inaction yet prevails. Such a man as Lord Randolph Churchill, who is still a political Free Lance, might well take this question in hand. But for his Lordship's zeal, the rectification of the scandalous irregularities which prevailed at the Metropolitan Board of Works would never have been brought about; and here, in connection with the water supply of London, is a condition of things, existing and threatened, which has a far more serious import, and may be productive of infinitely worse consequences, than those caused by the malpractices in Spring Gardens. Peculation is bad enough; but poison is worse. Only the other day, addressing a meeting at Paddington, Lord Randolph Churchill declared that there are at the present time several sanitary questions which cry aloud for legislation. We submit that the question of river pollution is one of them, and not the least in importance, although it had no place in Lord Randolph's list of public grievances. We apprehend that, with a man of such quick perceptions, it is only necessary that the subject should be brought to notice, in order that its paramount importance may be immediately appreciated. His Lordship reminded his Paddington audience of Lord Beaconsfield's legislative motto, uttered twenty years ago—"Sanitas sanitatum, omnia sanitas." We accept the motto. The great drink question is, as Lord Randolph urged, an important one; and there are plenty of people to look after it. Again, it may be, and doubtless is, the duty of the State to take care that the humbler classes of society shall be enabled to live "under conditions which do not violate all the principles of cleanliness, of health, of decency, and of morality." These are the subjects which, in the opinion of the member for Paddington, should occupy the attention of the present Parliament; and it is obvious that they cannot be adequately dealt with unless, incidentally, the question of the purity of the London Water Supply is also taken into consideration. Cleanliness and health involve, it should be remembered, the existence of a sufficient supply of pure and wholesome water. Of the sufficiency of the supply placed by the Water Companies at the disposal of the Metropolitan public, there cannot be any reasonable doubt; and if, in the future, that supply should be less free from contamination than it has been, the blame must not be laid at the door of the Companies. In common fairness, let it be borne in mind that at the present time the London Companies jointly contribute no less than £18,000 annually for the express purpose of ensuring the purity of their main source of supply. Their part of the bargain is punctually and ungrudgingly fulfilled. But the question is whether the other contracting party—that is to say, the Thames Conservators—are in a position to carry out their statutory functions in the matter. If the decision in the Staines case holds good, and if Weybridge and Shepperton are to be allowed to "go and do likewise," it is only too clear that the Conservators cannot furnish the necessary *quid pro quo*. To use a legal phrase, the Companies would seem to be paying away their money for a consideration that has failed. And yet, come what may, millions of the inhabitants of London must continue to receive their water supply from the Thames.

The Metropolis, it will be remembered, receives its water through the agency of eight Companies. The Southwark and Vauxhall Company obtain their supply from the Thames at Hampton; as also do the West Middlesex and Grand Junction Companies. The Lambeth Company draw theirs from Molesey; and the Chelsea Company have recourse to the river both at Ditton and Molesey. In addition to these, the East London Company may, when necessary, abstract from the Thames at Sunbury a daily quantity not exceeding 10 million gallons. These are the data quoted in the late Col. Sir Francis Bolton's valuable work on "London Water Supply" (last edition); and we believe they are perfectly correct. Formerly the aggregate quantity authorized to be taken from the river by the foregoing Companies was 110 million gallons a day; but under an agreement entered into between five of the Companies and the Thames Conservancy Board less than two years ago, the maximum quantity was increased; and at the present time, for the purpose of meeting public requirements, these Companies, together with the East London (which retains its original

limit of 10 million gallons per diem), may collectively take 180 million gallons from the Thames during every twenty-four hours. The quantity actually taken does not reach the authorized maximum; but, nevertheless, it is, and must continue to be, enormous. How should it be otherwise when the aggregate population supplied with water by the London Companies reached in the early part of the present year 5,446,579? We cite these particulars merely for the purpose of showing the magnitude of the system of Metropolitan Water Supply, and the pressing need to safeguard it from contamination. It was the intention of the Legislature to confer upon the Conservancy Board wide and ample powers. The Act of 1866 vested in them "the River Thames, the Conservancy of the "Thames and Isis from Staines in the County of Middlesex to "Cricklade in the County of Wilts." The range of their jurisdiction is, therefore, very extensive, and the trust they have to fulfil proportionately great. Yet the recent decision of Justices Field and Wills would seem to show that the powers of the Board cannot be properly enforced; and it is for this reason that we have urged, and still urge, that fresh legislation is peremptorily called for.

DEATH OF THE REV. RICHARD OKES, D.D.—We regret to learn of the demise of the Rev. Richard Okes, D.D., Provost of King's College, Cambridge, on Saturday morning, after a brief illness. The deceased gentleman was born at Cambridge, in December, 1796; and therefore would have completed his 92nd year in the course of a few days. Dr. Okes took a keen interest in the affairs of his native town. He was one of the promoters of the Cambridge University and Town Water Company; and Chairman of the Board of Directors until 1887—a period of 29 years—when he retired. The Company, as is well known, has proved a great commercial success. Dr. Okes was also a Justice of the Peace for the borough.

THE APPROACHING COMPLETION OF THE VYRNVY WATER-WORKS.—Latest advices as to the progress being made with the Vyrnwy Water-Works scheme of the Liverpool Corporation, under the direction of the Engineer (Mr. G. F. Deacon, M. Inst. C.E.), give the interesting information that matters have so far progressed that it is intended this week to close the valves upon the discharge pipes passing through the Vyrnwy masonry dam, so far as is necessary to stop the River Vyrnwy, except the compensation water to the Rivers Vyrnwy and Severn. The Bishop of Bangor—in consequence of the lamented illness of the Bishop of St. Asaph—will consecrate the new church to-day (Tuesday); and immediately afterwards the old church and the Powis Hotel will be removed. The water behind the masonry dam now extends for about two miles up the valley; but this, we understand, is merely due to the late exceptional rainfall.

ANOTHER SOUTH AFRICAN GAS-WORKS UNDERTAKING.—Mr. T. Newbigging, M. Inst. C.E., left England for South Africa last Friday to fulfil an engagement entered into under the auspices of Messrs. Davis and Soper, of Bury Street, St. Mary Axe, the London Agents for the Cape Town Corporation. The object of Mr. Newbigging's visit to South Africa is to inspect the native coal and test it, with a view of ascertaining its suitability or otherwise for gas-making purposes; to report as to the desirability of erecting gas-works for the supply of illuminating gas to Johannesburg, the capital of the Transvaal; to determine the size of the works, and to estimate their cost, and to select a suitable site. He will also have to settle the diameters and lengths of the main pipes for distributing gas throughout the town; and advise as to whether the combination of electric lighting and gas lighting would be advantageous and desirable. Mr. Newbigging will also possibly have to go to Pretoria—the seat of the Government.

A DEEP SPRING.—A correspondent writes to *The Times* as follows:—"A Company is at present carrying on works at Seltzer Spring, Spring Avenue, Saratoga, with a view of utilizing its waters for the purpose of liberating and storing, in liquid form, the carbonic acid gas which it contains in large quantities. Mr. Oscar Brunler, who is superintending the works, has made a startling discovery in connection with the spring. The latter was discovered about three years ago by Dr. Haskins, who put down the drill to a depth of 500 feet. At this depth an abundant supply of water was found flowing from a crevice in the rock bottom. Recently, in order to ascertain the depth of the spring, Mr. Brunler sounded it with a line and plummet; but, instead of resting at 500 feet, the weight sank the whole length of the line—900 feet. Other soundings have since been made (the weight used being a piece of 1-inch gas-pipe filled with lead, and weighing 34 lbs.), until a depth of 3300 feet has been reached, and yet without touching the bottom or any obstacle. It will be impossible to take further soundings until instruments specially designed for the purpose have been made. Mr. Brunler admits that the line may have been carried away by some powerful current; but he holds to his belief in the existence of a subterranean sea of greater or less extent, and of there being some connection between it and the ocean. In other words, Saratoga is over a vast water-filled cavern, the roof of which is about 500 feet thick. Should the existence of a subterranean sea be established, it would dispose of many theories and scientific speculations as to the source and course of the mineral springs of Saratoga."

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET. (FOR STOCK AND SHARE LIST, see p. 950.)

THE markets in general have been very heavy and dull during the past week on the Stock Exchange; and prices nearly all round have sustained more or less of a fall. The prominent cause is still to be found in the condition of the Money Market. "Goschens" have fallen even lower; and were repeatedly done on Wednesday at 96½—the lowest yet touched. Still, the tendency at the close of the week was rather better; and some markets had made a slight recovery. The Gas department has been only moderately active. The open stocks of the Metropolitan Companies have continued their improvement, and show a marked rise from their recent depression. In Gaslight "A" the quotation is 3 better; and all transactions throughout the week have been done at good steady figures. Very little has been done in South Metropolitan "A"; but the "B" has been in good demand, and exhibits an improvement of 3½. Commercial shows no change at all. Some of the preferences of Gaslight, and the debentures of both Gaslight and South Metropolitan, have slightly receded. This is quite in sympathy with the general tendency of the week, which has been to depress first-class securities, mainly through adverse monetary influences. Suburbans have been very quiet, but are firm and unchanged. Alliance and Dublin is ½ better. Foreign undertakings offer little for remark. The only variation is a fall of ½ in Buenos Ayres. Continental Union is going to appropriate a 1 per cent. dividend—to wit, 13 per cent. on the old and new shares, and 10 per cent. on the preference. This will raise the number of 13 per cent. paying companies to four—viz., Gaslight, South Metropolitan, European, and Continental Union. Only the Commercial exceeds this rate. The Water department has been much more active, and some advances in quotation have been effected; New River showing well to the front.

The daily quotations were: Fairly good business in Gas on Monday, with a marked tendency to improve. Gaslight "A" rose 1½; South Metropolitan "B," 2; and Imperial Continental, 1. Water was pretty active; but prices were not remarkably good. Tuesday brought a further improvement in Gas; Gaslight "A" gaining another 1½, and Alliance and Dublin old, ½. Water was quieter; and the only change was an advance of 1 in buyers of Southwark ordinary. Business in Gas was less on Wednesday; but prices continued satisfactory. Neither in Gas nor in Water was there any change of quotation. On Thursday, Gas was good and firm generally. South Metropolitan "B" was done at 235—the best of the week—and rose 1½. Buenos Ayres was ½ weaker. Water was quiet; but New River and Southwark 7½ per cents. rose 2 each. On Friday there was less business doing in Gas. Gaslight "C," "D," and "E," fell 2; "J," 3; and the debentures, from 2 to 3 each. South Metropolitan debentures also fell 3. Water was active; and New River rose 1 more. On Saturday Gas generally was firm; and Gaslight 4 per cent. debentures recovered 1. Water continued its activity, but made no further change.

ELECTRIC LIGHTING MEMORANDA.

A MUNICIPAL ELECTRIC LIGHT STATION FOR PARIS—PRICES FOR ELECTRIC LIGHTING AT THE PARIS EXHIBITION—MR. WILLIAM THOMSON ON ELECTRICAL SUPPLY—PROGRESS OF THE WESTINGHOUSE COMPANY.

WHEN French officialdom undertakes work a little out of the ordinary line, it is not exempt from the liability to make mistakes and be robbed, which is the heritage of all Governments; but it at least takes care to blunder and waste money with great formality. An example in point is supplied by the proceedings of the Paris Municipality in connection with their electric lighting scheme. It has been recorded in this column how after most elaborate inquiry by a Special Commission, the Municipality some time ago decided to invite tenders from electricians willing to take up concessions for the lighting of portions of the city according to prescribed terms. These conditions, it scarcely need be said, are very stringent; but it is nevertheless reported that offers have been made for the best districts. Meanwhile the Municipality have resolved to retain one of the districts under their own control, and to undertake the lighting of it, presumably by way of establishing a check upon the operations of the electrical contractors elsewhere. The great step of inviting tenders for the erection and equipment of this municipal lighting station has been taken. The motive power to commence with is to be six 140-horse power high-speed steam-engines, supplying energy for three distinct systems of distribution. The first system will include a service of 500 incandescent lamps and 140 arc lamps in the markets; the second group contains about 1000 incandescent lamps required for lighting the buildings adjoining the markets; and the third system is for the supply, by an alternating current, of from 2000 to 3000 incandescent lamps over a length of about 2 kilometres of the neighbouring streets. The tenders will be examined by two Special Commissions—one to deal with the electrical and the other with the steam plant. Parties tendering must manufacture the whole of the plant in France if possible; but the Commission have power to make a dispensation in favour of the contractor, if it can be shown that certain articles cannot be manufactured in that country—to such an extent have Free Trade principles penetrated the French mind! It is not stated when the Municipality expect to start their electric lighting station; but working

by Commissions is usually extremely slow, and not safer from error in the end than any other system of control. As we have already remarked, however, if the Paris Municipality, should after all get into trouble and lose money over their electric lighting scheme, they will have the satisfaction of reflecting that everything was done in the most orderly and formal manner.

There is to be a great deal of electric lighting at the Paris Exhibition next year. A Syndicate has been formed for supplying arc and incandescent lamps to exhibitors for the lighting of their stalls, in addition to the ordinary lighting of the buildings. It is reported that the charges for this service, calculated upon the full period of 900 hours of lighting during which the Exhibition is expected to be open, are to be as follows:—For a 16-candle power lamp, 60 frs.; for a 10-candle power lamp, 40 frs.; for a 500-candle power arc lamp, 500 frs.; and for a 1000-candle power lamp, 1000 frs. Power will also be supplied at the rate of 50 c. per horse-power per hour up to 500, and 40 c. beyond. These rates cannot be regarded as low; but, on the other hand, they are not excessive, considering the place and the circumstances. Motor power is generally costly in Paris, for a variety of reasons.

Mr. William Thomson, F.R.S.Ed., &c., has written a long letter to the Manchester papers, dated from the Royal Institution Laboratory, upon the future of coal gas and electricity. This is not the place for an examination of the writer's gas theories, but a few words may be devoted to what he has to say respecting electric lighting. He arouses his readers' attention by roundly declaring that "we are on the eve of a revolution in the supply of energy to the houses of the people." Further examination of the letter results in the discovery, embedded in much vague verbiage, of another passage of similar purport—"Electrical engineers were not in a position, until a few months ago, to introduce electric light into houses to compete with gas at its present price in Manchester. Now this can be done." After this amazing statement, instead of showing how the change referred to has been brought about, the writer wanders off again; and it is only near the end of his letter that he attempts to explain himself. He states once more "that although electricity could years ago be economically produced to compete with gas at present Manchester prices, it could not have been economically supplied to houses, because the electric current could only have been carried along very thick copper conductors, the cost of which would have been too great. This difficulty has within the last few months been satisfactorily overcome." And after this triple introduction Mr. Thomson merely hints that he is alluding to the transformer system of distributing high potential currents by means of wires of small section. Nobody who did not happen to know something of the subject would imagine, from this manner of introducing it, that the wonderful advance in electrical distribution spoken of by Mr. Thomson has been on trial for many years in all parts of the world. We altogether fail to see what justification the writer can show for his assertion that the transformer system of distributing electricity has "within the last few months" placed electric lighting in a better position as regards gas than it previously occupied. In making such an assertion he is simply misleading the people of Manchester. Irrespective, however, of the era when his favourite system came into successful operation, how can Mr. Thomson maintain that by its aid electric lighting can be supplied in Manchester at a price that will enable it to compete with gaslight, when the most experienced of all the users of the system—the Grosvenor Gallery Company, whose business lies in the most favourable quarter of London—charge for their services a price equivalent to gas at three times the London rates? Statements of this kind, made on his own authority by a writer with a string of capital letters after his name, only impress those who are ignorant of the facts, and who yet retain some faith in the disinterestedness and reliability of all men of scientific eminence. They do no good even to the cause to which the advocate is committed, because the most superficial inquiry addressed to those actually concerned in the business elicits the truth, which knocks the pretty story to pieces.

The Westinghouse Electric Light Company of America have recently taken a long stride in the way of aggrandisement, by absorbing the Consolidated Electric Light Company of New York. The Consolidated Company were owners of the Sawyer-Mann incandescent lamp patents, the right to the use of which now passes to the Westinghouse Company, and renders them much more independent of outside assistance. The consideration for the amalgamation is the payment of interest on the Consolidated Company's capital at the rate of 4 per cent., which amounts to the sum of £30,000 a year. After certain outstanding debts are cleared off, the payment is to be increased to 6 per cent. In addition to this the Westinghouse Company agree to pay a royalty of 1c. on every Sawyer-Mann lamp sold, which is expected to bring the dividend of the Consolidated proprietors up to 12 per cent. Accordingly, they regard the arrangement as distinctly better for them than their previous independent existence, when dividends were always uncertain and seldom high.

HINTS TO GAS CONSUMERS.—Messrs. James Milne and Son, of Edinburgh and Glasgow (Milne, Sons, and Macfie, of London), have issued a neat little pamphlet intended for distribution among gas consumers. The book contains readable general information respecting gas, besides instructing consumers on the subject of improved burners and means of regulating consumption, whereby they may in reality reduce their gas bills and obtain better lighting; and so escape the deceptions of the impostors who find an easy prey in the discontented user of bad burners.]

SOUTH AFRICAN LIGHTING ASSOCIATION, LIMITED.

IN the JOURNAL for the 6th inst., we noticed the registration of a Company under the above title, with a capital of £50,000 in £10 shares. It has been formed for the purpose of carrying out certain agreements entered into by Mr. Corbet Woodall, C.E., on behalf of a Syndicate, for the acquisition of the Port Elizabeth gas undertaking, and the lighting of King William's Town; also for lighting with gas, or gas and electricity combined, other towns with which negotiations have been opened, if these negotiations result in contracts being entered into.

South Africa at present possesses only two gas-works in operation—viz., those at Cape Town and Port Elizabeth. Both are, and have been prosperous, and have paid good returns to the shareholders. At Port Elizabeth, we understand, that these profits have averaged more than 15 per cent. for years past; but a large proportion has been wisely applied in reduction of capital, which now stands at £20,000. This undertaking has been purchased by the Syndicate for £30,000, which is not more than the value of the assets of the Company appearing in their balance-sheet. A reduction of 2s. 6d. per 1000 cubic feet was made last year in the price charged for gas; but while this will reduce the immediate profits, it will no doubt naturally stimulate the consumption. At King William's Town a provisional agreement has been entered into, giving the Association the exclusive right to lay mains in the streets for a term of 25 years, at the end of which time the Corporation may purchase on arbitration terms. King William's Town should afford abundant business to pay a dividend on the small capital proposed to be spent there. In both these towns there is considerable business done in wool pressing and packing; and for these purposes gas-engines are much in request. It is also confidently anticipated that in a climate where the sun through nearly the whole year provides more heat than is needful for comfort, gas cooking-stoves will be readily preferred to wood or coal fires. The Association contemplate providing electric light in such places as demand it; the motive power being gas. The heat of the climate is such that a demand for the coolest light obtainable is natural, especially in such places as public halls and theatres—probably no better ventilated in South Africa than they are at home.

South Africa has been a country of alternate periods of prosperity and adversity very sharply defined; but in spite of these fluctuations, the gas companies have steadily prospered. The recent development of the gold-fields has given considerable stimulus to the trade of the country; and its great natural advantages will doubtless make it increasingly attractive to emigrants of the better class, having intelligence and some capital. Such progress is well marked out by the increased demand for gas, which enables the price to be reduced, and thus again the consumption is stimulated. In South Africa the abundant supply of cheap and efficient Kafir labour, while shutting out the European unskilled labourer, is a great help to traders and manufacturers.

The Association is happy in its first Directors. They are Mr. D. Ford Goddard, Assoc. M. Inst. C.E., Mr. James Mansergh, M. Inst. C.E., and Mr. W. Woodall, M.P. Mr. Goddard is well known to our readers as formerly Engineer, and now a Director of the Ipswich Gas Company. The name he bears has for years been honourably associated with gas lighting. Mr. Mansergh is one of the most eminent Engineers of the day, and a member of the Council of the Institution of Civil Engineers. Few men have had larger experience in the valuation of such property. Mr. W. Woodall, though better known by his association in recent years with political and educational work, had an early training in gas management, which will aid him in the service of the Association. As to the gentleman under whose advice the Association has been launched, it is quite unnecessary to say anything to readers of the JOURNAL in recommending Mr. Corbet Woodall's skill and judgment. But it should be stated that he has recently visited the Colony, and has formed a very high opinion of the prospect there is for the profitable employment of capital in gas-works enterprises there; and no better presage is needed for the ultimate success of the undertaking now under notice.

THE IRONMONGERS EXHIBITION.

THE Ironmongery Exhibition at the Agricultural Hall is one of many annual fixtures of the kind, intended, it may be supposed, to display to interested members of the trades concerned the novelties and improvements which mark the passage of time in all progressive industries. It is several years since we noticed this particular kind of exhibition in the columns of the JOURNAL, and therefore we consider that the time has come for another examination of what may be called the ironmongery side of the business of gas lighting, with a view to discovering what progress, if any, could be signalized in this department of trade. The managers of the show have given it the now hackneyed title "International;" but habitual frequenters of this class of exhibitions are too well accustomed to the matter-of-course use of this descriptive prefix to allow their expectations to be unduly aroused by it. Now-a-days a stand of American clocks and another of German lead pencils form sufficient justification for calling any British bazaar "International." But this by the way. We notice that in the introduction to the catalogue, the General Manager (Mr. Harry Etherington) claims for this show the position of first of a series, in which all branches of the ironmongery and metal trades are to find complete representation. We are unable to name any particular feature in which the present exhibition differs from its precursors; but, of course, Mr. Etherington may know better. All that we can say

upon the point is that there is nothing apparent in the show, either regarded as a whole or taken piecemeal, which would lead an ordinary visitor to think it better or worse than the general run of such manufacturers' and merchants' bazaars. It is quite possible that this is the first of a series, as Mr. Etherington declares. But the fact is ironmongery, gas-fittings, and the general hardware trades run so far on the one hand into building materials, and on the other into furniture—also the names of annual exhibitions—that this class of commodities seems to be always on show somewhere; and this consideration takes off from the novelty of the present exhibition.

If for no other reason, however, we are constrained to notice the exhibition on account of the inclusion in the catalogue of an introductory article (the writer of which has thought fit to withhold his name) upon coal gas as adapted for lighting, cooking, and trade purposes. Unless we are very much mistaken, the author of this very praiseworthy little essay is himself engaged in gas making; for the matter of his remarks has a distinctly professional flavour. If anything is to be said by way of fault-finding, it may be that the writer has devoted too much of his limited space to the description of gas-works processes, in which the visitors who may be supposed to patronize an exhibition of ironmongery cannot be expected to take any very considerable interest. So little is popularly known about gas making, however, that the determination of the author to make use of his opportunity for disseminating a little reliable information upon the subject, is not to be lightly complained of. That such a technical paper should find admission into the catalogue is a proof of the desire of the managers of the exhibition that their enterprise should instruct their patrons in some things not generally known, as well as benefit them in the way of trade. We cannot speak too highly of the little article as a whole. After telling comprehensively and accurately how gas is made, stored, distributed, and measured, it shades off naturally into detailed comments upon gas utilizing appliances—not confining its explanations to goods actually exhibited; and after making mention of the comparative excellences of gas and electric lighting, ends with some appropriate hints to consumers respecting the choice of fittings, burners, globes, and stoves. It is a pleasure, as great as it is rare, to find trustworthy information concerning gas lighting and the other ordinary uses of gas in a publication of this order; and we most heartily congratulate the General Manager of the exhibition upon the wisdom he displayed in finding room for such sound matter, as well as the writer upon the use he has made of his opportunity.

As though not to be charged with partiality, immediately after the article on gas the catalogue has another on electricity and its uses. This also is a neatly-written little essay; and we should not be surprised to learn that it came from the same hand that wrote the article on gas, because, while very fair and comprehensive, it leaves out of account many things that a professional electrician would have been certain to mention, and is also phenomenally devoid of boasting and prophecy. If it had but contained a single estimate of the cost of electric lighting, showing it to be cheaper than gas, or had finished with the frank declaration that the days of gas-lighting are numbered, and that the electric light is to be "the light of the future," we might have thought differently; but the absence of such statements impels us to declare the opinion that the article was not written by an electrician. Its usefulness is not imperilled on this account; indeed, it is much more reliable than the great majority of electricians' papers.

We have devoted a good deal of space to the discussion of these features of the catalogue; and our excuse must be that, in point of fact, the catalogue is almost the best thing about the exhibition. Not that there are not some particularly interesting exhibits. For example, the first object that strikes a visitor upon entering the hall is the stand of the British Gas-Engine Company, Limited (Atkinson's patent engines), where several of the latest forms of these remarkable motors are shown in operation. The arrangement of the working parts of these engines has been altered since their action was described by Mr. Denny Lane to The Gas Institute in 1885; and they now look more like the general type of reciprocating engines. One of them is driving a dynamo supplying incandescent lamps, which are very steady. Messrs. J. E. H. Andrew and Co., Limited, also show some "Stockport" gas-engines—one being specially adapted for working a hydraulic lift, and another driving an exhibit of Brush arc lamps. Messrs. Dick, Kerr, and Co. show a collection of "Griffin" gas-engines, also supplying power for electric lighting, pumping, ventilation, &c. Messrs. Hartley, Arneux, and Fanning, of Stoke-upon-Trent, show an "Albion" silent gas-engine of their own manufacture. It will thus be perceived that, notwithstanding the abstinence of some well-known gas-engine makers, these machines are fairly represented at Islington.

There are several exhibitors of gas fires and heating-stoves, some of which are distinctly more curious than useful. Among the exhibitors of this class of goods may be named Messrs. C. Wilson and Sons, Messrs. T. Fletcher and Co., the L. W. Leeds Stove Company, Limited, Mr. F. Siemens, Messrs. Greenall and Co., Messrs. J. Wright and Co., Messrs. Freeman, Emery, and Co., and Messrs. Arden Hill and Co. Besides these firms, whose specialities in this line are well known, there are others who strive to tempt the public with a variety of fanciful stoves in which the power of the gas consumed is supposed to be magnified by different devices. Great use is made of coloured glass, vitreous ware, and polished brass in some of these productions. In gas-cooking stoves, which are shown by Messrs. Thomas Fletcher and Co., Messrs.

Charles Wilson and Co., Messrs. Arden Hill and Co., and Messrs. E. Siddaway and Sons, there is nothing novel to remark; but we observed a noteworthy addition to the resources of consumers of gas and oil in the stand of the Wanzer Company, Limited, who show some really remarkable lamps and heating-stoves for gas and oil. In these stoves the heat of the oil or gas flame—for the principle is identical in both cases—is applied to a circulating hot water and steam warming system; the idea being that the air admitted to the room passes in contact with these steam-pipes, and condenses the steam into water, which falls down to the boiler and is heated over again. Of course, it is impossible to form a correct notion of the true utility of such arrangements without proper tests; but so far as its application to oil heating-stoves is concerned, the principle seems to be a decided advance. The Wanzer Company also show a peculiar petroleum lamp, burning without a chimney. It is claimed that these lamps are perfectly safe, and may be thrown down while alight without danger of explosion. The necessary draught for burning the oil without smoke is produced by a fan driven by clockwork, and requiring to be wound up occasionally, like the spring of the old-fashioned moderator lamps. These lamps burn very well; but one of the chief advantages claimed for them is that, owing to the absence of a chimney, they can be used for cooking as well as lighting. For this purpose a light wire framework, standing on the body of the lamp—which, it should be stated, is all of metal—supports a steel cooking-pot capable of being converted into an oven. A 3-inch flame of petroleum, such as these lamps are capable of giving at their best, is very hot, and quite powerful enough to do the cooking required for a small family. The arrangement may be found very handy in small households, especially in the country, and certainly does not help to favour the idea that gas is the only friend of the poor man; but, of course, the lamp has its limitations. Such as it is, however, the Wanzer exhibit struck us as one of the greatest novelties of the show.

There is not much to be said about the gas burners and fittings. Mr. F. Siemens has the best display of regenerative lamps; but Messrs. H. Greene and Sons show their governors, Brönners' burners, and the Westphal regenerative lamps, which are also used to light Messrs. Fletcher's stand of gas-stoves. Messrs. Greenall and Co., of Manchester, also exhibit a lamp of the same character—Marsh's patent. Considering the numbers of this class of gas-lamps that are patented weekly, it is strange that so few novelties of the kind are found at exhibitions. Gas-governors are also shown by Mr. A. E. Beck, Messrs. H. Harrison and Co., Mr. J. Parkinson, and Messrs. Weir Bros. There is a sprinkling of those catchpenny gas-burners and toy fittings always to be found in such places; but they are not offensively prominent.

MID-SUSSEX WATER COMPANY, LIMITED.—By an advertisement which appears in another column, our readers will see that the Directors of this Company (the formation of which was mentioned in the JOURNAL last week) are inviting applications for the 6000 shares which, as already stated, they purpose issuing, out of the 7000 into which the entire capital is divided. The Company's district covers a large area, comprising Hayward's Heath, Cuckfield, Lindfield, Balcombe, and portions of Wivelsfield and Ardingly, in which a good supply of water is greatly needed. The neighbourhood of the three first-named places is of a superior residential character; and the building of first-class houses and villas will no doubt be stimulated by the existence of such a supply of good water as the Company will be prepared to furnish. The site for the works (which have been designed by Mr. Jabez Church, M. Inst. C.E., and are being carried out by Messrs. J. and H. Robus) has been well selected for procuring an abundance of water, which will be supplied by gravitation. It is expected that the works will be ready by September next. The Chairman of the Company is Lieut.-Gen. Sir John Stokes, K.C.B.; and the other members of the Board are gentlemen whose names are known to most of our readers. The field of operations seems to have been well chosen; and, with good management, the undertaking should not be less successful than others of similar character and extent.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.—The seventy-sixth quarterly meeting of this Institution will be held at the Victoria Hotel, Manchester, on Saturday next, under the presidency of Mr. Thomas Duxbury, of Darwen. The business before the meeting includes the election of President for the ensuing year; an alteration of rules, to enable two Honorary Secretaries (instead of one, as at present) to be appointed; and the adjourned discussion on two papers read at previous meetings. Mr. James Dalgliesh's paper, on "Oil and other Illuminants, and their Effect on Gas Consumption," will first be discussed; and afterwards Mr. T. Newbigging's paper (read at Doncaster three months since), on "Gas-holders without Upper Guide-Framing." A paragraph appearing elsewhere mentions that Mr. Newbigging has left England for a professional engagement in South Africa; and so he will not be present at the meeting. It is understood, however, that Mr. Gadd—to a description of whose invention the paper was mainly devoted—will be present; and, with the consent of the meeting, will reply to the discussion on Mr. Newbigging's behalf. After the transaction of this business, should time permit, the attention of the members will be asked to the subject of "The Presence of Water or Moisture in Coal, and its Effects"—a paper bearing this title having been prepared by Mr. Newbigging, and left with the Honorary Secretary (Mr. Harrison Veevers) for presentation to the meeting.

THE DISPOSAL OF RESIDUAL PRODUCTS.

For every material or product in the market, there is a certain value, representing what it is worth to the purchaser. This may be called its intrinsic value; and although it may occasionally happen that the purchaser, through ignorance, pays more than the intrinsic value, as a general rule he gives rather less. The influences of competition, both amongst buyers and sellers, tend to keep the price very near to the actual value, and a trifle under, in general, rather than over it. It is the business of every manufacturer or producer to see that he secures as nearly as possible the intrinsic value of his commodities; and it does not follow, from the fact of it being actually secured in the open market, that the original seller is successful in this respect. Astute speculators may have got the market into their own hands; a cumbrous system of middlemen and agencies may have been established; or the consumer may live in another quarter of the globe, thus causing a great expense for carriage. Since the consumer will not pay more than the intrinsic value of the article bought, all expenses in the way of carriage, commission to dealers, &c., may be regarded as coming from the pocket of the original seller. Take the case of any product—let us say, coal—having an intrinsic value of 20s. per ton. The consumer will not pay more than 20s.; so that if the cost of conveying it to him is 5s., and it is not sold directly to him, but through middlemen who expect to make 5s. per ton profit, it follows that only 10s. is left for the producer. So it is obviously to the advantage of the seller to supply the user direct, without the intervention of middlemen or agents, and also to find a customer as near as possible—next door if he can—so as to save the expense of carriage. Of course, there are cases where it is possible to make the consumer bear a proportion or the whole of the carriage and of the agency expenses, or where the intrinsic value of the article varies in different localities. But the enterprise of the age tends to reduce these. If coal is costly in any particular locality, by reason of heavy charges for carriage, &c., endeavours are made to find it in the immediate neighbourhood, or else to light upon a substitute, such as wood, petroleum, &c.

Whatever may be the exception to our argument, it certainly applies to the residual products from gas undertakings; and the present time, when coke and tar show signs of rising in value, is opportune for returning to the consideration of a subject which has repeatedly occupied attention in these columns—viz., How to dispose of these residuals to the best advantage. In connection therewith, attention may be directed to the two papers on "Coke," by Mr. C. Gandon, Engineer of the Crystal Palace District Gas Company, and by Mr. C. E. Jones, of Chesterfield, respectively, which were read at the 1887 meeting of The Gas Institute. The utterances of Mr. Gandon are especially interesting, because it is known that the Crystal Palace Gas Company were among the first to give proper attention to the disposal of residuals. Mr. Gandon points out one remarkable fact. Taking the prices of coal in different towns, and comparing them with the price of coke in each case, he finds that, weight for weight, coke sometimes returns 120 per cent. on the price of the coal, whilst under other circumstances only 40 per cent. can be obtained. Assuming a fixed value of 10s. per ton for coal the price realized for coke ranges from 4s. to 12s., according to circumstances. This wide variation cannot be accounted for, since it may fairly be expected that the intrinsic value of coke would be regulated by that of coal. If we assume a fixed intrinsic value for the one, we should expect the same for the other. The calorific value of coke is about equal, weight for weight, to that of coal; and it possesses some advantages and some disadvantages as compared therewith. We do not know of any circumstances, except to a limited degree, that should unduly inflate the demand for coke in one locality, or depress it in another. In the case of a large production—as, for example, at the Beckton Gas-Works—the expenses of carriage, &c., must be expected to operate against the Company to some extent. A correspondent in these columns has pointed out the real state of the case—viz., that, as a general rule, the prices realized for coke are far below its intrinsic value as fuel. Instead of receiving nearly the equivalent of the intrinsic value, the producer gets a small proportion only—the remainder being divided between the consumer, the cost of carriage, and the middlemen, dealers, &c. In many towns an analogous state of things prevails with regard to tar and sulphate of ammonia.

One of the departments which come under the charge of a gas-works manager is that of the sale of residuals. Obviously, his duty is to dispose of them to the best advantage. The recent fall in the values of tar and ammonia has directed attention to this department: and probably the advance in the value of coke is in some part due to the endeavours that have been made to develop a local trade for it, so that it might to some extent compensate for the deficiency on the other residuals. The chief thing is to get into direct communication with the consumer. If a local demand does not exist, the question of creating it should be carefully considered. Many difficulties may have to be encountered, and rapid progress in the direction of the entire disposal of all the residuals by retail trade may not be possible. But by perseverance in turning to account any means that offer—remembering that even a small demand is not unworthy of notice, as it helps towards the desired end—substantial progress may soon be made. Notwithstanding all that has been written on the subject, there is still much to be done, in many districts, in the way of introducing coke as an article of household consumption; in pushing the use of tar for pavements, for artificial asphalt, as a preservative paint for rough woodwork, and for many other purposes; and in bringing sulphate of ammonia before the notice of agriculturists.

When any of these materials are disposed of to a customer at a distance, there is the cost of carriage to be met, the burden of which comes chiefly upon the seller. If the sales are conducted through the agency of middlemen or dealers, the result is not only a present but also a prospective disadvantage to the sellers. The dealer's profit must be paid out of the transaction; and there is also a tendency to allow him to get a certain control of the trade, which he will not hesitate to use to his own advantage in the future. In respect to all classes of gas-works residuals, these two points have not been sufficiently appreciated. Especially there have been signs of gradual encroachment in allowing the dealers to obtain a command of the trade. It usually happens that gas engineers have so many engagements in connection with the several details incidental to the manufacture, distribution, and sale of their gas, and in meeting the demands of a continually increasing business, that the residuals market is of necessity left to take its own bearings. They are only too glad to get rid of surplus stock to dealers at any reasonable price. They find it more convenient to dispose of the products in large parcels by contract, than to sell them out in small lots by retail. Yet it is evident that considerable benefit will follow careful attention to the possibilities of developing home retail trade. This may be easily proved by examining the published accounts of those gas-undertakings of which the managers are known to have given due regard to the point now under consideration, and by comparing with the general average the returns realized for residuals per ton of coal carbonized. We do not hesitate to say that if this department received the attention it deserves in every case, the large range of variation that was observed by Mr. Gandon would be materially reduced.

The plan of fixing a moderately high retail price, and of disposing of the surplus at a much lower rate in order to keep the stocks down, may do very well so long as the bulk of the products are sold off by retail. But when the "surplus" becomes an important proportion of the whole, matters are not so favourable to the seller. The dealers acquire sufficient command of the trade to be able to bring various influences to bear with a view to their own advantage. Their interest is to buy cheaply and sell dearly; and they have no inducement to study the advantage of the producer, but rather the reverse. If a large quantity of surplus coke has been so disposed of, the gas manager may find his own coke brought into competition with his retail trade. Instances could be cited where, with a retail price of 12s. per ton at the works, the surplus had been sold to merchants at 8s. per ton, and the merchants had actually competed with, and secured a share of, the gas-works retail trade at (say) 11s. Coal merchants are glad to take large coke contracts, under some circumstances, at barely remunerative rates, in order that they may be able to keep together a coal-supply connection. This disadvantage has been recognized, and sought to be met by a stipulation that the coke supplied at the cheap rate is not to be offered for sale in the district of the producer. But such a proceeding is simply protecting oneself at the expense of one's neighbours. It is in effect saying: "Go and injure the retail trade of some other gas undertaking; it does not matter to me so long as you leave mine alone." And so we come to the edifying prospect of two towns, situated (say) 50 miles apart, where large quantities of "surplus" coke from A are delivered to, and sold by dealers at B, at the same time that "surplus" coke from B is being forwarded for sale at A. There are many small towns where, if left to themselves, the limited production of coke could be disposed of at, let us say, 15s. per ton. But a practically unlimited supply is brought in by the coal merchants from a large gas-works anywhere within a radius of 50 miles, and offered at a lower figure—perhaps 10s.; and consequently the local production must be disposed of at an equally low rate. The owners of the small works are, in fact, forced to sell at prices fixed by the coal merchants. These circumstances seem to point to the desirability of a mutual understanding between gas undertakings on the subject of the price of coke.

Let us now briefly review the circumstances of the production of gas-works residuals. In the first place, it cannot be limited or restricted in any way. So long as the demand for gas increases, the production of coke, tar, and ammonia will also be increased, whether they are worth much or little in the market. Sometimes it has even been necessary to pay for the removal of tar and ammoniacal liquor. If a manufacturer of any article—nails, for instance—finds he has accumulated a larger stock than there is any immediate demand for, he can limit the production for a time, and so reduce his stock. But gas engineers cannot resort to expedients of this sort. A second consideration is that gas-works are a permanency, and not a temporary undertaking that will be closed in a year or two. Under such circumstances, it is necessary to look beyond the mere disposal of the products at the best price obtainable for the time being. The policy of shipping off large quantities at cheap rates may result in some temporary advantage; but if this is purchased at the expense of a permanent prejudicial effect on the market at large, it may be bought too dearly. On the contrary, a policy of an opposite character may be the wiser—viz., to bear some temporary loss, in order to put the market on a firmer or better basis, with a view to future business. The policy followed in the disposal of residuals should certainly be based on the two considerations of illimitable and of permanent production.

In this connection, apart from wholesale and retail considerations, a large number of small customers are greatly preferable to a few large ones. In gas undertakings where the sale of

residuals is entirely confined to a few dealers or large consumers, some little sacrifice may judiciously be accepted, if necessary, in order to make the change. Suppose two undertakings, each selling 10,000 tons of coke per annum, but the one disposing of this quantity to ten large customers, who may either be dealers or *bonâ fide* users, and the other having a circle of a thousand customers. The ten large customers would be in a continual state of activity, seeking for every opportunity of beating down the price. They might even come to some sort of understanding between themselves. In any case they would be continually on the look-out for cheaper quotations from neighbouring towns, or possibly for other fuels, such as anthracite. The practical result would be that they must be continually supplied at the lowest price in the neighbourhood; and if one or two of them were lost, the effect would be very marked, and even disastrous. With the small consumers the case is very different. So long as they are supplied with a good article at a fair price, they go on continually from year to year. The loss of a few of them is not felt; and, on the average, the demand is more likely to keep regular. Unless driven to it by exorbitant charges, they are not likely to look about for cheaper quotations elsewhere. Therefore, even if the result of establishing a retail trade was a temporary loss, it might be worth incurring; but, as a matter of fact, not only is the market put upon a firmer and more durable basis, but an actual improvement in returns is at once obtained.

The various courses that commend themselves in the establishment of a retail local trade, have been so frequently set forth that they need not be repeated here. A great deal depends upon the commercial instinct and ability of the manager, or, in large works, of the person who may be appointed to the control of this important department, in being able to utilize to the utmost the peculiar circumstances under which he is placed. The methods followed in developing any business have a strong family likeness. Perhaps there may be competition of a special character to be encountered. In coal districts, coke manufactured from small coal and waste at the pits may perhaps be offered for sale in large quantities; and it is preferable to gas coke for some manufacturing purposes—being harder in texture and not so liable to decrepitate. Special circumstances, of course, call for special means. But, speaking in a general way, there are two important items to be considered—How to get orders; and how to execute them promptly and satisfactorily when secured. As regards the first, every kind of advertising may be resorted to—such as the columns of local papers, the backs of gas bills, circulars, and posters, or even special arrangements in the way of sending out agents to solicit orders. The amount expended in advertising will, of course, depend on the quantity of products to be sold, and the extra custom that may be reasonably expected to result. Indiscriminate advertising may do no good; for it is just as easy to waste money in advertising as in any other way. The object of advertising is to bring the article offered for sale prominently before the attention of probable buyers who are not likely to be attracted to it in any other way; and successful advertising consists of something more than the mere distribution of orders with a lavish hand, and trusting to chance for the result. Care must be taken, too, not to stop at getting the orders. The convenience of customers should be studied in every possible way. They should be able to secure prompt delivery—either in their own conveyances at the works, or by the company's vans at their residence or place of business, as may be preferred—and that in quantities large or small according to requirements.

SULPHATE PLANT FOR MILAN.—Mr. Henry Simon, of Manchester, has just received instructions from the Continental Union Gas Company, to erect, at their Milan works, one of his most improved plants for the continuous distillation of liquor in the manufacture of sulphate of ammonia.

THE AMYL-ACETATE LAMP.—At the last meeting of the Society of German Gas and Water Engineers, the Photometric Committee presented a report in which the advantages of the amyl-acetate lamp as a standard of light were dwelt upon. Before coming to any decision on the subject, however, it was resolved to communicate with the Physikalisch-technische Reichsanstalt, with a view to carrying out some experiments on the relative luminosity of this light and other standards at present in use.

THE ELECTRIC STREET LIGHTING EXPERIMENT AT BARNET.—Alluding to this matter in their last week's issue, the *Electrical Review* states that its representative, on a recent evening, was "fortunate, or perhaps it would be nearer the truth to say unfortunate, enough to witness the Barnet electric light installation in all its glory;" and he is able to assert that the lighting was in no respect superior to that of ordinary gas-lamps. Continuing, our contemporary says: "The filaments were in various stages of incandescence (the light from several being decidedly inferior to gas); and as the number of lamps in circuit falls short by some dozens of the number of displaced gas jets, we can only conclude that if the illumination witnessed by us represents the normal state of the Barnet streets, the inference is obvious. We have no desire to make matters worse than they are; but we do think that it is decidedly bad policy to blind one's self to actual facts as they exist. We therefore feel that our contemporary [the *Electrical Engineer*] showed somewhat bad taste in attributing to the gas journals and the local press, a desire to disparage the installation generally. Surely gas journals can give their honest convictions; and we find that they are not invariably behindhand in bestowing praise even to electric lighting, where praise is due."

Notes.

PRESERVING EXPOSED IRONWORK.

Mr. John Heald, the proprietor of the machine-works at Crockett, Contra Costa County, California, has for some years past been experimenting with a view to preserving exposed iron-work, and has demonstrated some things respecting this important matter that may be of great value. Mr. Heald some years ago had occasion to move a gasholder at Vallejo, and happened to notice on the old plates, which were badly corroded, that the "shipping marks" on the sheets were perfectly preserved. This led to the examination of other cases of the kind where marking had been done on ironwork; and also to experimenting with turpentine and white lead as a first coating to prevent rust. It was found that, when surfaces are coated with finely ground lead, thinned with spirits of turpentine, no corrosive action or scaling takes place, even when heavy coats of paint are afterwards put on the outside. Mr. Heald says that common paint mixed with oil is too thick to penetrate or close the imperfections of the surface and penetrate beneath the scale where it exists, thus leaving places for corrosion to begin beneath the paint. With turpentine and white lead mixed thin, the very pores of the iron are closed. The interstices, to so call them, are too minute to receive the body which oil gives, but are closed by the thinner compound. This is the theory, says *Iron*; but that is of no consequence so long as the fact is known. The process will be an important one for iron vessels, above water at least. The wash can be quickly put on, and will dry in a short time.

THE DANGERS OF WATER GAS.

In a paper read by Herr C. Hartmann at Düsseldorf, before a meeting of the Union of Sanitary Engineers, he stated that water gas, as ordinarily made, contained at least 30 per cent. of carbonic oxide, as compared with from 3 to 10 per cent. in coal gas. According to Pettenkofer, air containing 0.2 per cent. of carbonic oxide is fatal to life, whilst air containing about 0.7 per cent. of coal gas is slightly poisonous. As, however, coal gas can be detected by its smell when from 0.01 to 0.02 per cent. is present, there is a margin of safety; but this is not the case with water gas. While admitting that water gas might be used with due precautions for industrial purposes in which many other poisonous substances were already employed, Herr Hartmann was strongly opposed to its use for domestic lighting. In proof of his assertion that it is dangerous, he adduced the following table of deaths in New York from poisoning by water gas and coal gas respectively:—

	Water Gas.	Coal Gas.
1880	14	1
1881	18	3
1882	22	2
1883	20	0
1884	19	2
1885	18	0
1886	35	1
1887	27	0

THE ADULTERATION OF COAL TAR NAPHTHA.

In the course of a communication on this subject to the *Chemical News*, Mr. Thomas T. P. Bruce Warren says that the naphtha used by india-rubber manufacturers is generally obtained from the crude products of gas-works. There is no doubt, however, that a great deal is obtained in the "carbonizing processes" used in preparing coke for smelting operations; but this does not appear in commerce under a distinct name, although such naphtha is not unknown. Generally, Newcastle or cannel coal, or mixtures of these, are used in making coal gas; and hence the tar met with will vary more or less, and consequently the naphtha. The process of destructive distillation will thus introduce a variation in the composition of the naphtha recovered from such tar. Petroleum products are, therefore, now largely mixed with coal-tar naphtha; the advantages being that their greater volatility enables the spreading machines to be driven at three or four times the speed, while the diminished cost is greatly in its favour. If it is desired to test the mixture, the iodine absorption of petroleum and its commercial products, as compared with naphtha obtained from Newcastle coal, or mixtures used in gas-making, will readily reveal the fraudulent admixture of petroleum; and it is thus important in the fractional distillation of such a mixture, to examine each product separately.

THE VALUATION OF SPONTANEOUSLY FIRED COAL.

In a recent number of *Engineering*, it is recorded that about 5000 tons of semi-bituminous coal, stored in brick houses in America, took fire spontaneously about the middle of last September. When the fire was discovered, it was evident from the appearance of the smoke curling upward from different places on the top of the pile of coal, that the whole mass was alight. The deposition of sulphur on the surface of the heap, condensed from the fumes, presented the appearance of a yellow dew. The method adopted for ascertaining the amount of the loss in this instance to be made good by the fire insurance company was to have a sample of the coal analyzed, when it was found to be composed as follows:—Carbon, 76.50; hydrogen, 3.98; mineral matter, 12.13; sulphur, 1.48. The calorific value of the coal, as computed from this analysis, was found to be 13,594 thermal units per pound. Other samples were taken from the oblique face of the heap after one,

half of it had been removed. These samples gave an average composition for the coal of: Carbon, 74.13; hydrogen, 3.95; mineral matter, 13.18. The computed calorific value was 13,230 units per pound, or a loss of 2.68 per cent., which was taken to represent the depreciation in the value of the coal by heating. A sample of partially coked coal, which represented an average sample of the coal actually injured by the fire so as to make a notable change in its appearance, showed upon analysis the following percentage composition:—Carbon, 65.77; hydrogen, 1.36; mineral matter, 26.13; sulphur, 0.82. The calorific value of this sample was ascertained in the same way as before to be 10,409 thermal units per pound, or 12.7 per cent. less than that of the uninjured coal. The compensation paid was assessed upon these data. The cause of the fire was the presence of iron pyrites, which is the only dangerous form of sulphur in coal; for sulphur combined with organic matter is not liable to spontaneous changes. Ordinary analyses of coal fail to show the dangerous kinds, because they are made upon samples representing an average of many specimens; whereas the danger of spontaneous combustion is due to the greatest concentration of iron pyrites in one or more spots rather than to the diffusion of sulphur through the mass.

PIPE EXTRACTORS.

By "MAINS."

When it is necessary to remove a small line of pipes for the purpose of laying a larger main, an expeditious method of taking out the old pipes must be adopted. The system described in the JOURNAL for Sept. 18 last (p. 508) is not "new," and I doubt if there are any mainlayers now actively engaged in this work who have not resorted to the plan as there described, which will answer the purpose for small mains; but it becomes much more useful if the clip is made sufficiently heavy and strong, and provided with two 1½-inch round thread screws for forcing the joint, with a steel pointed set screw for fixing the clip more firmly to the pipe. A

Fig. 1. PLAN OF PIPE IN TRENCH

Fig. 2.

forcing clamp C (fig. 1) is commonly used by mainlayers; and the spanners or bars for working the screws S S' may be 3 ft. 6 in. long. If the clip should slide, place a wood skid at the back, bearing against the shoulder of the next socket. A loose clip B placed against the socket receives the ends of the screws. The clip is made large enough to allow the lead joint to be drawn with the spigot. This forcing clamp will be found especially useful for removing hydrants when repairs are required.

An ordinary bottle jack will push off all small pipes as usually constructed with the common spigot and socket joint; but if the joint is made with a recess (a most unnecessary contrivance), it is best to be provided with hydraulic jacks. A more efficient system is mostly adopted for larger mains, and will be found to disconnect the pipes more quickly, and is handier to work. Of course cutting out joints has been abandoned by experienced mainlayers for a long time; but melting out the joints may be effected cheaply and expeditiously in outlying districts, where fire and smoke would not be objected to. This may be done in the trench, or by cutting out long lengths and lifting them out of the trench by derricks.

Having a clip to fit each size of pipe, the apparatus shown in fig. 2 will be found sufficient to extract all sizes of water and gas mains. Referring to the illustration, A is the pipe to be extracted; B, a 20-ton hydraulic jack; C, a wood skid or packing piece; D, a strong pair of iron clips hinged underneath, with two bolts on top, the upper one to carry a shackle to be used in lifting the end of the pipe if required; E, greased iron plate for pipe to slide on; F, iron packing the same thickness as the lead joint, to allow the latter to come away with the spigot.

Some may assert, after all that may be said for the practice of drawing the joints of old mains, that very little is to be saved; but if the main is 12 inches to 24 inches in diameter, and a number of pipes require removing, it will be found a very expensive work to cut out the joints, or to cut and break the pipes, when hydraulic jacks will do the work more expeditiously, and leave the pipes and fittings intact for another job. The same appliances are also found most useful for changing the old fire-plugs for the new hydrants now being fixed in the City of London and elsewhere.

DEATH OF MR. J. R. CAPRON, F.R.A.S.—We regret to have to record the death, on the 12th inst., of Mr. John Rand Capron, who was for about twenty years a Director, and for a considerable portion of this period the Chairman, of the Guildford Gas Company. The deceased gentleman, whose removal was rather unexpected, was in his 60th year.

Technical Record.

THE GASHOLDER GUIDE-FRAMING QUESTION.

AN AMERICAN REVIEW OF THE DISCUSSION.

[In the issue of the *American Gaslight Journal* for the 2nd inst., Mr. W. Mooney, C.E., concludes (presumably for the present) his review of the discussion on the question of the possibility of dispensing, wholly or partially, with the guide-framing of gasholders. The first portion of the communication appeared in the preceding issue of our contemporary, and was reproduced in the JOURNAL for the 30th ult.; and we now give the author's concluding remarks, which will be found to contain an expression of his individual views on the subject.—ED. J.G.L.]

The first fruit of the controversy which has extended to such length was Mr. Livesey's experiment; and this has been followed by Mr. Gadd's invention, a full description of which, by Mr. Newbigging, was read before the Manchester District Institution of Gas Engineers on the 25th of August.* Mr. Gadd's invention introduces an entirely new principle; the whole of the guide-framing being done away with, and the holder securely guided from the bottom curb. Briefly stated, the invention for dispensing with the usual guide-framing consists in placing the channel or other guides within the tank, at an angle like the thread of a screw instead of in the vertical plane. The guide-rollers of the bottom curb, as they work in the channels or rails provided for them, give a helical or screw-like motion to the holder as it rises and descends in the tank.

Notwithstanding that Mr. Newbigging appears to accept Mr. Gadd's invention as the key to dispensing with guide-framing, it seems to the writer that the conditions are much the same as in Mr. Webber's idea; that is, the whole structure must depend on the bottom curb and rollers for support, and the holder must be made stiff enough to withstand the force of the wind, however strongly it may blow. The point at which the holder would buckle or break in Mr. Webber's holder would be on the leeward side, at the point of contact with the upper roller or guide-wheel (about 5 feet above the water-line); and in Mr. Gadd's system this point would be just at the water-line. With radial and tangential rollers well fitted to the tank guides, Mr. Webber's holder would be as firmly held at the bottom as Mr. Gadd's would be by his spiral system of guides. It is a question whether the added weight to the holder, necessary in any system dispensing with all or nearly all of the guide-framing, will not be as costly as the guide-framing it displaces, with the risk added.

Much stress is placed on the use of tangential rollers, in addition to the usual radial rollers; but, unless they have very wide channels to run in, there would be very great danger of these breaking on the windward side of the holder when the holder was pushed against the opposite guides. The idea that holders can be adjusted so nicely that all the wheels shall fit tightly against the rails at all times, smacks very strongly of what our English friends call "rot." The tendency on our side of the water is to build holders of large diameter with from three to four lifts, but with an abundance of guide-framing.

The various writers whose opinions have been given in condensed form differ on the subject of the wind pressures to which holders are exposed. There can be no limit to the force which the wind may exert against any object; there being no reason why the greatest known or recorded pressures may not be surpassed in the future. The writer has seen the path of a hurricane in the West where every house and tree had been swept away; and nothing in the shape of a gasholder could possibly have withstood such a force. But we know that gasholders do withstand very severe gales without damage. There must be some reason why gasholders are not blown away in high winds; and the following theory, not original with the writer, may account for it. In America, it is well known that we have many square wooden structures on high foundations, without anchors or other means of security. If the wind had full play against the side of such a structure, it would seem impossible for it to withstand it. We know, however, that it is rare that such a thing happens, although thousands of buildings are exposed to the full force of the wind. The theory is this: The air in the space enclosed in the triangle formed by the vertical side of the structure, the ground line, and the hypotenuse connecting the extremities of these lines, forms an elastic air cushion, which receives and yields to the force of the blast—transmitting but a small portion of the force to the structure.

As to the distribution of the force of the wind, and its effect on a gasholder, there seems to be also a difference of opinion; the point in dispute being whether the holder is pushed along horizontally, or whether the wind exerts an overturning force against it. If the pressure of the wind is equal over the whole exposed height of the holder, it will be pushed against the guides on the leeward side. Whether it would not be capsized if the guide-framing were out of the way, is a problem which the experimenters will be apt to solve for themselves in the future. The tendency no doubt is to overturn the holder, as it is a top-heavy, floating, and consequently unstable body; and this is only prevented by either the rollers clutching the guide-rails, or (in the future, when guide-framing has become obsolete) by the rigidity of the holder carrying the strains down to the tank. In some respects a gasholder

* See ante, p. 373.

resembles an inflated balloon, which has to be held down, previous to its aerial flight, by numerous guys; a slight wind being sufficient to cause it to plunge and sway in an alarming manner.

In this connection it seems proper to call attention to the system of guide-framing of gasholders invented by Joshua Horton, in 1851.* Whether this system was ever tried is not known to the writer; but, in view of what has already been done, in the way of dispensing with lofty guide-framing by Mr. Livesey, and the confidence with which he and other eminent English engineers express their belief in eventually changing completely the present system, a description of Mr. Horton's invention, and some proposed improvements upon it, are here given.

In a double-lift holder the guide-framing is carried up to one-quarter of the height of the upper section; and the guide-wheels at the top and bottom of the lower section roll against the guide-rail in the usual manner. Securely fastened on the top of the grip of the outer section is a column, extending half way up the side of the inner section; the base of the column being secured on the grip by a leg on the outside of the outer section. According to the description of the patent, the column is a combination of wood and iron. The columns are tied together by a T-iron. [The author then proceeds further to describe, by the aid of diagrams, Mr. Horton's invention, as well as his own improvement thereon.] The objection to this system is the added weight to the lower section; but this would be equally the case with any system dispensing with exterior guide-framing, particularly with Mr. Gadd's spiral system. The grips and cups would perhaps have to be made a trifle wider and heavier, to afford a better footing to the standard guiding the inner section.

It is no proof of the failure of Mr. Horton's system that no example of it exists now. Many good inventions have been condemned without a fair trial; and improvements now in common use have obtained recognition only after years of struggle and poverty on the part of the inventor. This system would fulfil the stated requirements of most of the engineers engaged in the discussion before described. The strains in the upper section would be transmitted to the tank guides, and the inner section would always be sustained for one-half its height. The standard on the tank wall could be a very light lattice column, extending from the top of the tank wall to a point not far above the top of the lower section, and carrying a guide-rail extending from the top of the column to the bottom of the tank. The system could be applied to a three-lift holder as well as any other, provided the lifts were of unequal heights, to admit of securing the column on the grip.

Holders to dispense with exterior guide-framing must, no doubt, be strengthened, particularly in the bottom curb. The sides could also be stiffened by diagonal or spiral bracing, consisting of light angle-irons placed about 2 feet apart. These need not be carried over the vertical legs, but could be secured to them and to the sheets. These braces would prevent the blowing in of the sides of the holder, so often seen in high winds.

It is well known that a holder, with short lifts in proportion to its diameter, will bind or get jammed much easier than a holder having longer lifts. Different authors give different proportions for height and diameter; but it is generally agreed that the height should not be less than one-quarter of the diameter. As the holder itself does not touch the guide-framing, except at the points of contact of the wheels and guides, it is evident that the farther apart these points are, the easier will the holder rise and fall. The example of a drawer sliding into a desk will illustrate this. If the drawer is long and narrow, it slides in easily without binding; but let it be short and wide, it will stick, first on one side and then on the other.

Now, in view of this well-known fact, why will not a holder depending on single rollers at the bottom have a greater tendency to bind than one having two or more series of rollers? A three-lift or a four-lift holder towering (say) 100 feet or more in the air, unsupported anywhere except at the bottom, and that only on the outer edge, will be a grand sight to the engineer; but it will be a long time, and by many short steps, that this desired system will be attained.

That much may be done in the matter of dispensing with lofty guide-framing is not only possible but probable; but the question of how much or how little will not be solved for some time yet. The first step—dispensing with the girders connecting the tops of the columns—no doubt can be easily and safely taken; and as they are about 6 per cent. of the whole weight of iron in a double-lift holder, the saving will be felt at once. Beyond this it will be wisdom to go slowly and by short steps.

When it is considered that the holder is the storehouse or reservoir from whence the consumers are supplied, and when the consequences of any failure in the supply are suggested and thought over, it looks as if there was no portion of the plant where experimenting would be more dangerous. Small companies, having but one holder, should certainly have that one guarded by every known means. The wrecking of that holder, or its partial destruction, would be disastrous in the extreme.

Here it may be well to put in a plea for covered holders. This subject comes under the general title to this article, as holders enclosed in buildings need very little or no guiding; and if the guide-framing can be dispensed with anywhere, here surely is the place. In the severe climate of America, with its blizzards and snowstorms, covered holders are perhaps more of a necessity than

in the milder climate of England. It may be argued against the use of enclosed holders that only smaller sizes can be economically covered. But very large ones have been enclosed on the Continent; and by using a dome-shaped roof, it would seem that there is no limit, within reasonable bounds, to the size of a holder that might be covered. The Providence (R.I.) Gas Company have several holders covered with domes; the largest covering a holder 136 feet in diameter. Colonel F. S. Benson, the well-known Engineer of the Nassau Gas Company, of Brooklyn (N.Y.), in a paper read before the Society of Gas Lighting in 1877, having for its title "Covered Holders," gave the advantages of this system at length. No doubt, if the matter rested entirely with the engineer, whose anxieties and trials are little known to the powers above him, many more holders would be covered; and the engineer would have that portion of his troubles mitigated.

One of the writers on the subject under consideration mentions the absurdity of using architectural columns for the guide-framing of gasholders. In this he is right, as the use of a column, where no structure is to be supported upon it, is ridiculous, to say the least; but that is not all. The ancients, who invented the orders of architecture, established a certain proportion between the diameter of the column and the height—the height varying in the different orders as follows:—Corinthian, height = 10 diameters, Ionic = 9, Tuscan = 7, and Doric = 8; and these proportions have proved to be the best. When we consider the height of a three-lift holder, surrounded by a frame with Tuscan columns, with the height exceeding 50 diameters, we can see what disproportionate things they are. In this city [New York] and its immediate vicinity may be seen examples of Gothic columns in clusters three tiers high, single Tuscan and Corinthian columns, and various nondescripts, equally out of proportion, but all used for the guide-framing of gasholders. The height of the absurd in this matter is reached in the framing of a holder at the Point Breeze station of the Philadelphia Gas-Works. This is probably a relic of the early days of gas lighting in America. The tank has a stone wall reaching 10 or 12 feet above the ground level, with enormous buttresses supporting the columns. These columns consist of four cast-iron standards to each, having at the base a spread about 10 feet square, and tapering to the top, where there is a room, formed within the enclosure made by the four standards, having glazed windows on all sides, and covered with a roof over all. The object of these enormous columns, as well as the rooms at the top, is a question as obscure as the use of the pyramids of Egypt; and, in fact, is a question for the antiquaries to solve. The rooms might possibly have served for the temporary banishment of refractory stokers, in the same way that sailors are sent to the masthead for petty breaches of discipline.

The use of cast iron for columns or guides is fast becoming obsolete; and very properly, as many accidents have happened from its use. At the present time, when wrought iron can be obtained in every variety of shapes, there can be no excuse for the use of cast iron, except for caps, bases, rollers, &c.

The author, in conclusion, explains that his criticisms, &c., were written at odd times during a busy season; and this will, he says, to some extent account for their disjointed character. He counsels his readers, in the matter of dispensing with the guide-framing of gasholders, to follow Pope's advice—not to be the first to try what is new, nor the last to lay aside what is old.

DOWSON'S WATER GAS PLANT.—For the last six months, says *Industries*, a Dowson gas plant has been in use at the works of Messrs. Spicer Bros., paper manufacturers, Godalming, Surrey, in connection with two "Otto" gas-engines, of 30 and 40 horse power respectively. The result has been so satisfactory that the firm have just ordered from Messrs. Crossley Bros., Manchester, two more engines each of 80-horse power. Messrs. Spicer are also preparing to use the Dowson gas in their paper-drying cylinders, instead of steam.

CONNECTING LIGHTNING CONDUCTORS WITH GAS AND WATER MAINS.—At the last meeting of the Society of German Gas and Water Engineers, held at Stuttgart, Herr Fischer made a communication on the above subject, based on a pamphlet published by Dr. N. H. Schilling. This gentleman came to the conclusion that "the connection of lightning conductors with gas and water pipes is neither necessary, nor for practical reasons advisable in the interests of gas and water works." Statistics show that houses provided with such piping do not incur greater risk from lightning; on the contrary, it probably acts as a protection. In only very few instances have pipes inside houses been struck; and the damage done was very slight. In those cases the damage concentrates itself on those points which lie on the shortest line between the outer wall and the piping. The gas and water pipes are only exposed to danger from lightning (1) when the lightning passes to it from a neighbouring lightning conductor, and this can generally be traced to defect in the conductor; (2) when the packing of the piping consists of a bad conducting material—e.g., india-rubber or wool, the use of which should therefore be avoided. The piping should not be connected with the conductor, as it is sometimes interrupted when repairs or a new arrangement of pipes is being carried out. Besides, the danger should not be forgotten to which workmen are exposed when repairing these pipes during a thunder-storm. A Committee was subsequently appointed to discuss the subject in conjunction with the Elektro-technische Verein and the Verband Deutscher Architekten und Ingenieure.

* Attention was called to Mr. Horton's patent (No. 13,436 of 1851) in a letter addressed to the JOURNAL for May 17, 1887, by Mr. W. Mann.

THE NEW HOLDER OF THE CONSOLIDATED GAS COMPANY OF NEW YORK.

A recent number of the *Scientific American* contained some particulars of the new holder which the Consolidated Gas Company of New York are erecting between Fifteenth and Sixteenth Streets in that city. As this is the largest holder in America, our readers will doubtless be interested in the following description of it, for which, as well as for the accompanying illustrations, we are indebted to the above-named publication.

The problem presented was the erection of a holder of the largest attainable capacity upon a piece of ground which was not only limited in area, but which was of the most unstable character at any great depth below the surface. To have made the usual excavation, and built within it a brick tank, would have entailed very great expense. The upper stratum of earth was made ground, composed of dumpings from all parts of the city, underneath which quicksand was liable to be found at all places. For these reasons it was decided to dispense with the brick tank, and to build an iron one resting practically on the surface of the ground. In order to economize depth, the holder, as will be seen, is a three-lift one.

The ground where the tank stands was levelled off by excavation to a depth of about 8 feet; and about a thousand 12-inch piles, 40 feet long, were driven over an annular area lying mostly within, and corresponding to the general circumference of the tank. This left in the centre a circular area without piling. Two feet of concrete were then laid; and on this the bottom plates of the tank were placed. The entire foundation is 200 feet in diameter.

The tank is of wrought iron. The plates at the lowest course

are $\frac{7}{8}$ inch thick, and are laid double, so as to give $1\frac{1}{2}$ inch thickness of metal; they are arranged to break joints. Where two plates abut, a strap of iron with six rows of rivets is carried over the joint. For each of these butt joints there is one strap, either inside or outside the tank, according to the locality of the joint. As the sides rise they diminish in thickness. The tank is 192 feet in diameter, and 42 ft. 9 in. deep. Around the top a box girder is carried which forms the curb; and upon this rest the 24 standards. These are made of iron channel bars, and are tied together by lattice girders, of which several courses surround them. Between the girders diagonal bars extend, crossing in the centre of the panel. At their crossing they are secured, so as not to strike against each other in stormy weather. Special trussing is used at the top, to resist any outward thrust that may be brought to bear upon the standards. The framework rises 125 feet above the curb, or about 150 feet above the level of the street.

The holder, as already stated, is in three lifts, each about 41 feet high. On its upper curb, each lift carries 24 roller brackets, provided with both radial and tangential rollers; this being, it is believed, the first application of this combination in America. The radial rollers are the larger and more securely fastened; the tangential rollers, which are comparatively small, being treated as subsidiaries. The crown is stiffened circumferentially by a box girder contained within the holder. The outer circle of top plates and the upper circle of side plates form two of its sides. A horizontal circle of plates within the holder forms the lower element; and the open side is filled with lattice trusswork, so as to allow the gas free access. The crown is provided with internal radial

trusses, extending to a central king-post, which carries their inward ends when the holder is empty.

The general structure is based on recent English practice. The old style of columnar frame is departed from; and the securely braced uprights, with horizontal and diagonal bracing, recall to mind the framework of the great Birmingham holders, full particulars of which were given in Vol. XLVII. of the JOURNAL. The capacity of the holder is 3,250,000 cubic feet. The inlet and outlet pipes are 30 inches in diameter. The illustrations convey a very good idea of the size of the structure, the erection of which has so far been unattended by accident.

REGENERATIVE GAS-ENGINES.

The next step in the direction of increased economy of fuel in gas-engines will most probably be, says *Engineer*, the utilization of the waste heat of the exhaust gases. The other important sources of loss—viz., radiation, and absorption of heat by the water jacket—may be regarded as unavoidable with motors of the present prevailing types. Engines have, no doubt, been proposed which dispense with the water jacket altogether; but there seems to be little probability of such machines coming into practical use. It is also significant that the most successful gas-engine builders appear to regard the method of external refrigeration as a necessary evil, and make no serious attempt to do away with it. Putting aside, then, the losses due to radiation and conduction (amounting in all to something like 66 per cent.), we have about 17 per cent. of the total heat of combustion converted into available power, while an almost equal quantity of heat passes away in the exhaust gases without performing any duty. In the Atkinson cycle engine, the quantity of heat carried off by the jacket is only about 19 per cent.; the heat converted into work is nearly 20 per cent.; and the heat carried off by exhaust is over 50 per cent. In gas-engines of good construction, the escaping gases have a temperature of about 500° C.; and if we assume the maximum temperature to be 1500° C., the theoretical efficiency would be 0.56. Now if we suppose the temperature of the exhaust gases to be usefully lowered to, say, 140° C. with the same initial temperature, the theoretical efficiency would rise to 0.76, with a corresponding gain in actual efficiency. It is not practicable to reduce the final temperature by further expansion of the gases in the cylinder; so that some form of regeneration affords the only means of a closer approximation to the conditions of maximum efficiency. The employment of regenerators with engines using town's gas is, for obvious reasons, out of the question; but for the rapidly increasing number of motors burning producer gas, the application of the regenerative system must lead to a large saving of fuel. Atkinson and Otto engines working with Dowson gas are at present using less than 1.5 lbs. of coal per indicated horse power per hour, as certified by their users, who can have no reason for understating their fuel consumption. In some cases it is said to be as low as 1.1 lbs.; and it may be safely assumed that gas motors using generator gas can be worked with an hourly consumption of 1.25 lbs. of coal per horse power—particularly if the engines are specially designed for burning generator gas, as ordinary engines have features which, though advantageous when gas of high calorific power is used, lead to considerable loss when fuel gas is substituted. Rankine estimated that 90 per cent. of the heat in the exhaust of air-engines might be retained for use by means of a regenerator. If we suppose, in the case of a gas-engine working in near proximity to the producer or generator, that 75 per cent. of the exhaust heat could be returned to the producer by means of a suitable regenerator, the fuel consumption would be reduced to less than 1 lb. per indicated horse power per hour—a result certainly worth striving for. The regenerative apparatus required is simple and inexpensive, and would require practically no attention, as the temperature of the exhaust gases is low enough to permit the use of continuous conducting regenerators. Gas generators working with cold air use about 5 per cent. by weight of steam with the air blast; and the percentage of combustible in the gas averages 40 per cent., with more than 50 per cent. of nitrogen. A hot air supply drawn from a regenerator would insure the decomposition of a larger proportion of steam; thus enriching the gas, and reducing the volume of useless nitrogen.

In a recent number of *La Nature*, instructions are given for the electric deposition of black iron upon ornamental metal articles, such as gas burners and fittings, to give all the appearance of highly finished wrought-iron work. Fine metallic iron, such as is prepared for rubbing parquetry flooring in France, and called *paille de fer* (iron-straw), is dissolved in commercial hydrochloric acid to saturation, which is shown by the appearance of a deposit at the bottom of the bath of liquid. A fiftieth part (by weight) of arsenious acid is added; and the whole is briskly agitated. The solution is not completed and ready for work until the whole of the latter constituent, which dissolves slowly, is completely absorbed. Articles to be treated are to be placed in connection with the negative pole of a battery and plunged into the bath; the anode being composed of old files and pieces of gas-retort carbon. Articles made of copper and brass blacken directly; but those of iron would be attacked and dissolved by the bath. It is therefore necessary to previously nickel them. In this way a brilliant deposit is obtained which is called black nickel. As the iron-electrode deposited by this process would quickly lose its colour upon exposure to a damp atmosphere, it is necessary to protect it by a colourless spirit lacquer.

THE RATHMINES AND RATHGAR TOWNSHIP WATERWORKS.

At the Meeting of the Institution of Mechanical Engineers, held recently in the Lecture Hall of the Institution of Civil Engineers, No. 25, Great George Street—Mr. C. COCHRANE, Vice-President, in the chair—a paper describing the above-named works was read by Mr. A. W. N. TYRRELL, M. Inst. C.E.

The author stated that the idea of controlling and utilizing the head waters of the River Dodder originated with the late Mr. Robert Mallet, who in 1846 was instructed by the Commissioners of Drainage for Ireland to investigate the feasibility and conditions of constructing reservoirs on some part of that river, "for the combined purposes of providing an unfailing and increased supply of water power to the millowners occupying the stream, and contingently of controlling the floods, which at frequently recurring intervals prove so destructive to property situated on its banks." After a lengthened investigation of the question, Mr. Mallet recommended the construction of a large impounding reservoir in the upper part of the Glensmoel Valley, by an embankment 1025 feet in length and rather more than 100 feet in height. The reservoir was to have a water surface of 142 acres, with a content of 227,843,645 cubic feet and a drainage area of 6070 acres. Nothing further, however, was done in the matter. Subsequently, in 1860, when an improved supply of water for the city of Dublin was under consideration by Sir John Hawkshaw, the Royal Commissioner appointed to investigate the subject, Mr. Mallet brought forward a project for procuring the supply from the Dodder. It was, however, rejected, for two reasons: Firstly, because the quantity of water procurable from the district would not be sufficient for Dublin; and, secondly, because, in order to obtain the quantity which it was stated the district would supply, it would be necessary to impound the whole of the water from the drainage area of 9½ square miles, about two-thirds of which is covered with peat, and excepting in very dry weather produces water more or less coloured thereby.

In 1877, the supply of water to the Rathmines and Rathgar township from the Grand Canal at Gallanstown being deemed unsatisfactory, a provisional agreement was arrived at between the Water Committee of the Corporation of Dublin and the Rathmines and Rathgar Township Commissioners, by which the former body were to supply the township from the city mains with an average of a million gallons of water daily for an annual payment of £2281 5s.; and any further quantity up to 1½ million gallons daily at the rate of 1½d. per 1000 gallons. This agreement not being ratified, the Rathmines Township Commissioners called in Mr. R. Hassard, M. Inst. C.E., to advise them as to the feasibility and cost of procuring an additional supply of water from the higher levels of the Canal, and as to obtaining an independent supply from the Corporation reservoirs at Stillorgan, supposing an arrangement as to price could be agreed on. In sending his report, Mr. Hassard laid before the Commissioners a project by which a supply of water might be obtained by gravitation from the tributaries of the Dodder draining into the Glensmoel Valley; and from this project the undertaking, since carried out, does not materially differ.

The principle of construction adopted was that known as the "separation" system, which has been carried out at Manchester, Halifax, and other places. The upper part of the Dodder drainage-ground, having an area of 4340 acres of granitic formation, is covered with peat, as already stated; but immediately below this district there occurs an area of about 3250 acres, free from peat, partly of granitic, but principally of metamorphic and silurian formation, producing water of great purity. It was evident, therefore, that if the water from the peat-covered area could be intercepted, and passed by or through the lower district without mingling with that to be obtained from the latter, a supply of excellent water could be secured for the use of the township. This arrangement has been carried out. The water, as taken from the streams in dry weather, contains about 4 grains of solid matter per gallon, and is of about 5° of hardness. A more desirable water it would be difficult to procure. The drainage area at its summit at Kippure Mountain attains an altitude of 2473 feet above Ordnance datum—giving an average inclination from the head of the upper reservoir of about 1 in 10; and the sides of the valley are in many places of steeper slopes, rendering it necessary to construct the flood channels of unusual size and capacity, as the rainfall is large, and during storms flows off the bare hillsides very rapidly. The watercourse for conveying the waters of the Dodder, the Cot Brook, and the Slade Brook, from the peat-covered district past the upper reservoir, is capable of carrying off 120,000 cubic feet of water per minute, or 27½ cubic feet per minute per acre of drainage; and the overflow weirs of the reservoirs are each 200 feet in length. The streams and springs on the western side of the valley, adjacent to the upper reservoir, are conducted into it by culverts passing underneath the artificial watercourse; and in the lower part of the valley the waters from the Ballinasorney and Ballymaico Streams, distant respectively 1½ and 2 miles, are intercepted, the direction of their currents reversed, and the water conducted back into the upper reservoir by catchwater conduits constructed along the hillsides. The Piperstown stream on the eastern side of the valley is carried across it by a syphon pipe 2 feet in diameter, passing through the lower reservoir, and delivering into the catchwater conduit on the western side.

It was at first intended to construct a reservoir of large storage capacity in the lower part of the valley, for impounding the water from the peat-covered district, and from this reservoir to give out not

only the amount of compensation water due to the lower district of 3250 acres, but in addition a largely increased supply for mill-owners' use, for which it was proposed to tax them per foot of occupied fall, as has been done in other places. The mill-owners objecting to this, it was arranged during the progress of the Bill through Parliament that the water from the upper district should be diverted past both reservoirs, excepting at such times as the volume of the stream flowing from it exceeded 1500 cubic feet per minute, which is as much as the mills can use; and that the Commissioners should have power to impound all water in excess of this flow. With this object, works and gauges have been provided which ensure that 1500 cubic feet per minute must pass down for mill-owners' use before any water from the upper district can flow into the reservoirs; and from the weir immediately above the lower reservoir the 1500 cubic feet per minute secured preferentially to the mill-owners is conveyed partly by an open conduit, and partly by a line of iron pipes 27 inches diameter, laid through the reservoir and terminating in the old course of the river below the reservoir embankment. Consequent on this arrangement, the lower reservoir has been constructed of much less extent and capacity than originally intended.

There was nothing very unusual in the construction of the works; the two embankments being formed in the ordinary way, with slopes of 3 to 1 on the inner and 2 to 1 on the outer faces. At both, however, there occurred on the eastern side of the valley veins and deposits of sand and gravel, extending for a considerable distance into the hill, and rendering it necessary to follow them in by headings driven one over another, and filled with concrete; the ground being too steep for open trenches. This operation was one of considerable difficulty, owing to the loose nature of the sand and the quantity of spring water met with. The lower heading at the upper embankment was extended 120 feet into the hillside, until the deposit of sand had been completely cut through and a wall of hard blue clay reached. Into this clay the heading was carried sufficiently far to ensure a sound junction being effected between the concrete filling and the impervious material at its termination. From the floor of the lower heading a trench was then sunk to a depth of 32 feet, when the hard clay was reached; and the whole was refilled with carefully rammed concrete. After this the next heading was proceeded with, and filled up with concrete in the same manner; and so on until a height of 84 feet from the bottom was attained, when the work was completed by a short length of open trench. The headings being only 5 feet in height and all heavily timbered, this part of the work was necessarily very slow and tedious, greatly retarding the progress of the upper reservoir embankment, and consequently the final completion of the works. The upper reservoir has an area of 57 acres, and contains 357 million gallons, its embankment being 70 feet in height at the deepest part; the lower one has an area of 80½ acres, and contains 160 million gallons, its embankment having an extreme height of 55 feet.

The eduction tunnels, through which the River Dodder was diverted during the progress of the embankments, are constructed in the solid ground on the western side of the valley, and entirely below the puddle trenches. They are in each case 11 feet in diameter, having a sectional area of 100 square feet; and with the exception of the central plugging, which is of brickwork, are built entirely of rubble masonry backed with concrete. The outlet towers are placed in close proximity to the fore-bays of the tunnels, and are reached by foot-bridges from the embankments. There are three openings in the outlet tower of the upper reservoir, through which the water is drawn off at different levels for the township supply; and from the base of the tower, extending through the eduction tunnel to the valve chamber, are laid two lines of pipes—one of 24 inches diameter for emptying purposes, and the other of 16 inches diameter for the supply of the township. A second emptying-pipe, 18 inches in diameter, is inserted in the plug, and discharges into the lower reservoir below the weir at the mill-owners' slot-gauge. From the outlet tower of the lower reservoir are laid two lines of pipes, of 27 and 24 inches diameter. The larger forms a junction with the line of 27-inch pipes laid through the reservoir; and the smaller extends through the eduction tunnel and valve-chamber to the mill-owners' gauge-basin below.

For township use the water can be drawn off from the upper reservoir at three different levels, as already stated; and, after passing through a gauge-basin, is conveyed by a line of 15-inch pipes, 4½ miles in length (with two intermediate relief-pits on its course) to a service reservoir at Ballyboden, distant about 2¼ miles from the township, at an altitude of 325 feet above Ordnance datum, and 175 feet above the highest part of the township at Tereure. From this reservoir, after passing through copper wire gauze screens, the water is conveyed to the township by a line of 18-inch pipes laid in the public roads. The water for mill-owners' compensation is drawn off from the lower reservoir, and, after passing through a gauge-basin, is delivered into the old course of the river immediately below it. The preferential supply of 1500 cubic feet per minute from the upper district is diverted past the lower reservoir by a weir placed across the old river bed, and is then passed through a slot-gauge which is capable of delivering the stipulated quantity with a mean head of 9 inches, this being the height of the crest of the adjoining weir.

The works were designed to secure a supply of 3,000,000 gallons daily for township use, and 2,100,000 gallons for mill-owners' compensation. From the register of rainfall on the site of the works, it has been ascertained that, at the termination of the unprece-

dent drought of 1887, which extended from May 23 to Oct. 31—a period of 161 days—there would have been in stock more than fifty days' supply for both township and mill-owners' use.

The works were designed and carried out by Mr. Hassard, in conjunction with the author; the contractors being Messrs. Falkiner and Stanford, of Dublin.

In the course of the brief discussion which followed the paper, Mr. MARTIN said that when the Institution held their meeting in Ireland, he had the pleasure of seeing the works which had been described by Mr. Tyrrell; and he was much interested at the way in which the difficulties were overcome in their construction. To the general members of the Institution, the author's very complete description of these works would be of great service. The problem, or rather the great difficulty, with which the Engineers had to contend was to carry a large quantity of water that was not fit for use in the town over the very area that was wanted for gathering good water. This, he considered, had been very ingeniously contrived, as Mr. Tyrrell had shown. When inspecting the works, he did not quite see why there should be a weir to raise the water into the main channel at all; and he did not also see why there should be a hole through the weir.

Mr. MAIR thought that Mr. Tyrrell and Mr. Hassard ought to be congratulated upon such a result as was shown in the paper—viz., that after 161 days' drought, there remained in stock in the reservoirs 50 days' supply. He presumed the water from the upper district—the peat area—was taken away by a separate channel altogether, and not allowed to flow down. As to the quantity of rain that fell into the reservoirs, he should think the rainfall there was very excessive.

Mr. TYRRELL, replying to the last speaker, observed that the water flowing off the upper district—the 4000 acres—was entirely unsuitable for the township supply, and was diverted past the upper reservoir by means of an artificial channel, and discharged into the lower reservoir. This channel would have to deal with floods of considerable magnitude; and it had been designed to carry off floods at the rate of 120,000 cubic feet per minute, which was equal to 27½ cubic feet per acre of drainage per minute, or at the rate of 27 inches of rain in 24 hours. The population of the township was 30,000; and the works would give 3 million gallons of water per day, which, at 30 gallons per head, would suffice for three or four times the existing population. As to the culverts through one of the weirs, these culverts were placed in the weir to carry off the ordinary flow of the river; and at times of heavy rainfall, when a large quantity of water was running down the channels, it would pass over in the usual way. The rainfall in this district was no doubt excessive. On the occasion, however, of the heavy flood to which he had referred, there was only about 1½ inches in Dublin.

The CHAIRMAN mentioned that he had seen it authoritatively stated that the average rainfall in Dublin was 25 inches.

A vote of thanks was accorded to the author of the paper, who acknowledged it in appropriate terms.

At next Friday's Students' meeting of the Institution of Civil Engineers, two papers are to be read—on "The Covered Service Reservoir of the Southampton Corporation," by Mr. E. T. Hildred, and "On the New High-Level Storage Reservoir for the Grand Junction Water-Works Company at Hanger Hill, Ealing," by Mr. Herbert Ashley.

A TEST for the detection of commercial saccharine in articles of food has been discovered by Herr E. Bernstein, and described by him in the *Zeit. für Anal. Chemie*. It is based on an observation of Remsen's, that when a minute quantity of saccharine is heated in a test-tube with a little resorcinol and some strong sulphuric acid, the mixture becomes yellow, then red, and finally deep green; sulphur dioxide being at the same time disengaged with effervescence. On cooling, the solution is diluted with water, and an excess of alkaline hydroxide added. The liquid now appears red by transmitted light, but has a strong green fluorescence. A milligramme of saccharine will yield 6 litres of fluorescent solution. In applying the test to articles of food, the substance is slightly acidified, preferably with phosphoric acid, and is then extracted with ether; the evaporation of the ether leaving the saccharine sufficiently pure for the reaction. Any fat present is removed by petroleum spirit before the extraction with ether.

THE Committee on Science and the Arts of the Franklin Institute of Pennsylvania notify that they are empowered to award the Elliott Cresson gold medal and the John Scott legacy premium and medal (\$20 and a copper medal) for meritorious discoveries and inventions tending to the progress of the arts and manufactures. The first-named medal was founded by the legacy of Elliott Cresson, of Philadelphia; and its award was placed in the hands of the Committee, who decided to bestow it for some discovery in the arts and sciences, for the invention or improvement of some useful machine or new process, for some combination of materials in manufactures, or for ingenuity, skill, or perfection in workmanship. The John Scott premium and medal was founded in 1816 by John Scott, a merchant of Edinburgh, who bequeathed to the City of Philadelphia a considerable sum of money, the interest of which should be devoted to rewarding ingenious men and women who make useful inventions. The premium is not to exceed the above-named sum, and the medal is to be inscribed "To the most deserving." The Secretary of the Institute (Mr. W. H. Wahl) will furnish any required information on the subject of these medals.

Register of Patents.

PIPES EMPLOYED IN THE MANUFACTURE OF ILLUMINATING GAS.—Firth, A. F., of Brighthouse. No. 16,631; Dec. 3, 1887. [8d.]

This invention relates to such metal pipes as in the manufacture of illuminating gas are exposed to considerable heat; the object being "to render such pipes more durable by preventing actual contact between the flame, or heated gas, and the pipe."

For this purpose the patentee employs, in combination with iron pipes, fire-clay, formed into segmental slabs or clips, two or more of which enclose the diameter of the pipe; while for such lengths of the pipe as are not supported, the blocks are flanged and secured to each other by bolts. The butt joints of the several lengths are also provided with projecting and cavity locking pieces. For curved portions of the pipe, the ends of the slab are cut at an angle, or on a radius line. The blocks or slabs can be of any convenient length and thickness; and they afford facilities for repairs by replacement of one or more slabs at any point where the ones previously used are defective or destroyed. As an alternative, the iron pipe may be encased in fire-clay, first thoroughly well tempered and worked, and afterwards steadily and evenly "fired."

PUMPS FOR GASES AND AIR.—Clark, E. B. Ellice, and Chapman, L., of Connaught Mansions, Westminster. No. 16,986; Dec. 9, 1887. [8d.]

This invention has for its object so to construct pumps—especially such as are used for pumping gases or air—that their action is much facilitated, as no inlet-valves have to be lifted against their own weight or stiffness, as has hitherto been the case. The piston of the pump, according to the present invention, works in an inner cylinder or liner, which is of less diameter and less length than the main cylinder of the pump. The inlet-pipe to the pump opens into the space between the liner and the cylinder. The outlet-valve is in the cylinder covers or ends, which are so situated as to be within the space included in the diameter of the liner. When the piston commences its stroke, the liner moves with it, until its forward end bears on the forward end of the cylinder, whereby an annular or circumferential opening is left between the rear end of the liner and the rear end of the cylinder; and thus the pump draws in at the rear side of the piston, through the space between the liner and the cylinder, and into the interior of the liner at the rear of the piston by the continued movement of the piston in the liner, the contents of the liner at the forward side of the piston being at the same time expelled through the outlet-valves. When the piston makes its back stroke, the liner moves back with it a distance sufficient to leave a similar annular or circumferential inlet opening between its forward end and the forward end of the cylinder, and to cause the rear end of the liner to bear on the rear end of the cylinder; and the same operations are repeated at the end of the cylinder the reverse of those already mentioned, and so on during the working of the pump.

PUNCHING, RIVETING, AND SHEARING MACHINE WORKED BY GAS.—Pinkney, C. W., of Smethwick. No. 639; Jan. 14, 1888. [8d.]

This invention consists in constructing and arranging the parts of gas-worked punching, riveting, and shearing machines so that they may work more efficiently than heretofore.

The principal or motive piston in a punching-machine and the charging-piston are fixed in the same hollow cylinder. The motive piston is uppermost; and its piston-rod passes out of the top of the cylinder and works in a tubular guide on the cylinder cover. The piston-rod of the charging-piston passes out of the bottom of the cylinder. The piston rod of the motive-piston is connected with the long arm of the lever, the short arm of which carries the punch. The long arm passes through an opening in the tubular guide, in which the piston-rod of the motive-piston works; and its rounded end takes into a slot in the piston-rod. By the ascent of the motive-piston, the short arm of the punch lever is forcibly depressed upon, and punches the article to be punched. The lower or charging piston is operated in the following manner:—To the lower protruding end of the piston-rod of the charging-piston, a cranked lever is jointed; the two arms of the lever being situated at a distance apart on a shaft. They are inclined to one another at an angle of about 50°; the fulcrum being at the angle formed by the junction of the two arms of the lever. The upper end of the short arm of the lever is jointed to the lower end of the piston-rod of the charging-piston; and the fulcrum on which the lever turns is carried by a sliding-block, which works in a horizontal guide on the base of the machine. The long arm of the lever terminates in a handle, by which the workman operates it. By depressing the long arm of the lever, the sliding-block, carrying its fulcrum is moved in its horizontal guide; the short arm of the lever approaching nearer and nearer to the vertical position as the long arm is depressed. When the long arm has been fully depressed, the sliding-block is brought to the end of the guide in which it works; while the short arm of the lever is vertical and in a line with the piston-rod of the charging-piston. The piston is then in its highest position; and the force of the detonation cannot communicate any motion to it. In the normal state of the parts of the machine, the motive-piston is at its lowest position—that is, a little lower than the middle of the cylinder; and the charging-piston at its highest position—that is, nearly in contact with the motive-piston. In the side of the cylinder immediately opposite the space between the pistons when they are in their normal position, is an opening, at which the mixture of inflammable gas and air is introduced, and at which the exhaust gases are expelled.

The action of the apparatus is as follows:—The parts being in the normal positions described, the workman raises and pushes over the long arm of the lever. The charging-piston is thus depressed; and the detonating mixture is thereby drawn into the cylinder below the motive-piston. The detonating mixture being cut off, the workman reverses the motion of the lever; and in that way raises the charging-piston, and compresses the detonating gaseous mixture between itself and the stationary motive-piston. When the compression has so far proceeded that the elastic force of the gaseous mixture exceeds the downward pressure of the motive-piston and its piston-rod, the piston rises, and causes the punch to descend and rest upon the plate or article to be punched. The charging-piston is supported firmly in the manner already described. The detonation is then effected, and raises the

motive-piston; thereby effecting the punching of the article. The gaseous mixture being ignited under pressure, detonation is effected by the heat of a red-hot tube. The exhaust-valve is operated by a hand-lever.

CARBURETTING GAS.—Doms, L., of Vienna. No. 13,147; Sept. 11, 1888. [6d.]

According to this invention naphthalene is used in the form of "cartridges" or compressed cylinders made of naphthalene-powder; and the gas-lamps in which they are employed are like candles. By this means it is claimed that the disadvantages arising from the melting and casting of the naphthalene are obviated; and moreover, owing to the form of the lamps employed, they can be more conveniently arranged on gas-brackets or chandeliers, and the flames do not throw any shadow downwards.

As shown in figs. 1, 2, and 3, the naphthalene contained in the receptacle B is evaporated by the heat of the burner D. Gas is introduced into the upper part of B; and after it has mixed therein with the naphthalene vapours, it passes to one or more burners C. Instead of using a flame D for heating the receptacle B, bent metal rods D¹ D² D³ can be used (as illustrated in figs. 4 and 5), which rods will conduct the heat of the flame to the receptacle B placed below. In order to enable the bent rods to be moved out of the reach of the flame, they are either hinged or pivoted as in fig. 4, or arranged to slide as shown in fig. 5.

For regulating the admixture of the naphthalene vapours to the illuminating gas, the regulator represented in figs. 1, 2, and 3 is used. By the perforated piston adapted to be displaced in the gas-admission pipe, the openings for admitting the gas to the receptacle B can be closed; and by means of valves, the discharge of the gas impregnated with the naphthalene vapours is regulated, whilst another valve controls the discharge of the unmixed gas. The displacement of the piston and valves is effected through the medium of a cam, which, on being turned, causes the rod carrying the piston and the valves to move upwards against the pressure of a spring.

ADVANCE IN THE PRICE OF COKE.—One of the Birmingham newspapers reports that a great advance has recently taken place in the price of coke, and that ironmasters are becoming alarmed. Derbyshire cokes, which six months ago were 7s. per ton, have rushed up to 11s. 6d. and 12s. Best Welsh cokes have advanced 2s.—making furnace sorts 14s. 6d. delivered in Staffordshire; and foundry, 21s. North Staffordshire have advanced 1s. 6d.; making furnace 14s. Gas cokes have risen 25 per cent. It is stated that this is due to the scarcity of slack, through the colliers working short time, and ironmasters competing for the diminished coke supplies.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

MR. ELLIS LEVER AND SALFORD GAS AFFAIRS.

SIR,—In one of your recent issues, I had pointed out to me an extract from one of my speeches during the municipal contest in Pendleton, Salford, bearing upon the now famous "Salford Gas Scandal." By that report, you will find I was one of the "young" members of the old Gas Committee, and that I interested myself in obtaining all possible information to enable me to take a useful part in the letting of the contracts in 1886.

I gather from the "letters" and "interviews" of Mr. Ellis Lever, that because he was not fortunate enough to get an order, he denounces everybody connected with that Committee as either fools or rogues. But so far as I am concerned, I refuse quietly to be considered either; and in justification of the action of the Committee, I shall be glad if you will publish the following further particulars.

In a letter to the *Manchester Examiner*, dated Sept. 26, 1888 (summarized), Mr. Lever says: First, he has been boycotted for nearly ten years by the Salford Gas Committee because he ventured to tell them they were being defrauded. Secondly, That the coal and cannell used in the gas-works is notoriously bad; being charged with poisonous impurities.

As to the first charge. It is true Mr. Lever has not had an order for some years; but his tenders have always been considered along with others. On the last occasion, he offered Bestwood cannell at 12s. 6d.; but as Hucknall was offered at the same price, it got the preference. The two collieries join each other; and the Gas Committee had good reasons for making the choice they did. Other offers were made at the same time; but his prices were not so favourable as those whose tenders were accepted.

There is no denying that there does exist a prejudice against Mr. Lever at Salford. It is not forgotten that, during Mr. Hall's management, Mr. Lever was sending in cannell at 37s. 6d. per ton—a much higher price than any other firm—nearly all of which had to be stacked; but the more recent transactions will be fresher in the remembrance of those concerned.

In the year 1876, Mr. Lever offered by tender to deliver cannell from either Hucknall or Bestwood colliery. It was resolved by the Gas Committee to order from him 20,000 tons at 13s. 6d. Mr. Lever accepted the order; but was unable to deliver, and letters received from both collieries subsequently stated "that Mr. Lever had no authority to offer either of these cannells, neither could he deliver them if he got any orders." The Gas Manager and Committee, instead of boycotting Mr. Lever as he richly deserved, arranged to allow him to substitute an order for 24,000 tons of coal, which he delivered.

The next order Mr. Ellis Lever got was in 1877—conditions and deliveries stated in tender. The delivery times, Mr. Lever did not comply with. He sent large quantities when not required, and when large deliveries were required he did not carry out his contract; so that other contractors were asked and delivered extra supplies. One of these was Mr. E. G. Wrigley (who is not one of Mr. Lever's closest friends). Mr. Lever failed in his deliveries about one-third, or between 7000 and 8000 tons. What he did send in was not all as contracted for. His contract was for Shirland cannell; yet more than one class of cannell was substituted—one being found 2s. per ton inferior, and another 1s. 4d. inferior—so that the Committee, on the information of their Manager (which was proved to be reliable), stopped further deliveries on the contract.

Does it not look more likely that Mr. Ellis Lever has been his own boycotter?

As to Mr. Ellis Lever telling the Committee they were being defrauded. He has often been requested to meet the Committee, and substantiate his charges; but hitherto he has failed to do so.

As to the second point, "That the coal and cannell used in the gas-works are notoriously bad; being charged with poisonous impurities." A portion of the cannell used is from the same pits from which Mr. Lever supplies Manchester, and none of the cannell used in Salford is inferior to that which he delivers to Manchester. As to coals, Salford buys the best gas-producing coals in the market. The new Gas Committee are so satisfied with the quality of coals that they have reduced the cannell, and increased the coal, in their manufacture of gas. Had the coals been bad, more cannell would have been required, instead of less. The purity of gas does not altogether depend upon the material used; but it is a question of purifying. It matters little what the quality of the material may be, so long as the purifying process is complete. The illuminating power does depend upon the material used, and during the late management there was very little fault to be found with the candle power of the gas they produced.

The new management have chosen to make gas after the Birmingham school—more coal and less cannell; but this is a question of policy not honesty. Coal may make as much gas per ton as cannell; but it has not the illuminating power, and costs more to purify. The consumer, to have the same light, must increase his burners, and consequently his gas bill; while the profits of the Committee go up nearly 7½d. per 1000 cubic feet.

Mr. Ellis Lever has also made the following statement, or is reported to have done so, to an interviewer from the *Pendleton Reporter*—viz., "That he offered to supply the Committee; and had they taken his tenders, it would have saved the ratepayers £25,000." Having the tenders in my possession, I find the following are the facts:—The Gas Committee required 50,000 tons of coal each year for three years. Mr. Lever offered only 10,000 tons of coal for two years—that is, he offered 20,000 tons, where the Committee wanted 150,000 tons. As to price, his quotation was 9s. 6d. per ton. In no single instance was any tender at 9s. 6d. considered. The average price paid by the Committee was 8s. 8d. per ton; and the gas-producing power and residuals of the average purchases are equal to Mr. Lever's coal offered. The Committee thus saved £6580, by not giving Mr. Lever the order, even if he *could* have delivered it. Of cannell the Committee wanted 40,000 tons each year for three years. It so happened that this was what Mr. Lever had to offer. But the average price of Mr. Lever's was 13s.; and the Committee bought a much superior average at 12s. 9d.—thereby saving

£1500, or a saving altogether of nearly £8000, instead of a loss of £25,000.

When Mr. Lever made this statement I wonder if he had calculated that it is nearly 2s. per ton on the whole 270,000 tons purchased. A margin of from 2s. to 3s. per ton for profit and lubrication to the fortunate contractors is very comfortable. Perhaps Mr. Lever is used to it.

Mr. Lever's charges against individuals and corporate bodies are very numerous and grave. He evidently does not live in a glass house, hence he can safely throw stones, besides working through agencies divers and dark. Will Mr. Lever answer the following?

1. Is not Mr. Fox, who has distinguished himself at Halifax, in your employ?
2. Have you ever paid tips or commissions to gas officials?
3. Have you not paid such to Mr. Samuel Hunter, as well as to Manchester Gas-Works officials?
4. Did not both yourself and your daughter, Mrs. Church, offer to Mr. Hunter and family the use of your Colwyn Bay house free of charge, prior to the letting of the last contracts—1886? Also did you not offer him a large commission if he would secure you an order from his Committee?
5. Did you not pay Mr. Hunter a sum of money to withdraw his former action against you in the Civil Court, besides sending a cheque to the Wesleyan Chapel at Pendleton, where Mr. Hunter attended?
6. Is it not true that where you have made charges against either the Gas Manager or the Committee, Mr. E. G. Wrigley has been supplying that Committee? and that the origin of all the troubles in Salford was the refusal of Hunter to work with you, and against Mr. Wrigley?
7. Is it not your candid opinion that Mr. Hunter would not now have been in prison if he had kept friends with you and done as you wished him?

Albany Square, Pendleton, Nov. 23, 1888.

JAMES WARD.

THE POSITION OF GAS INSTITUTE MEMBERS.

SIR,—Upon reference to the rules of The Gas Institute, I infer that any member wishing to retire therefrom must give notice of his intention of so doing before the 1st of January in any year, or he will be held liable for his subscription for the next year. In August last, a circular was addressed to the members, asking them to refrain from resigning, as an extraordinary meeting would be held in the course of the autumn. The Council having since resolved not to hold such meeting, but to let matters, *re* Bray, stand over to the June meeting of next year, I should like to know in what position the members now stand as regards such notice of resignation as above stated.

I do not intend paying my guinea subscription, and expenses in travelling several hundred miles to participate in such disgraceful proceedings as have of late years taken place, to the discredit of the Institute. Cannot Mr. Bray be induced—now that the (to him) obnoxious members have resigned, and he being still declared a member—gracefully to promise not again to refer to a matter which has been distasteful to most of the members, and thus restore the harmony which formerly prevailed at these annual gatherings?

Nov. 22, 1888.

A PROVINCIAL MEMBER.

GASHOLDER CONSTRUCTION.

SIR,—My admittedly novel proposal for gasholder construction having received so much attention from the gas world, it may seem to some that I need not trouble to object to any little inaccuracies of description thereof. When, however, it comes to a comparison of my invention with another proposal, the suggestion for which it is admitted was taken from my own, I think it only right that inaccurate expressions of the more important kind, whether arising from bias or carelessness, should be put right.

In your summary of the meeting of the Southern District Association, appearing in the *JOURNAL* for Nov. 13 last, you say that "Mr. Livesey in turn demonstrates that the effect of Mr. Gadd's *long* spirals, going a *long* way round the tank, may be gained," &c. The italics are mine, and serve to show how the art of judicious tautology may be employed, so as to create an unfavourable prejudice. The inclined guides I propose to employ in practice, and have illustrated in my models, can in no sense be called "*long*" spirals, neither do they go a "*long*" way round the tank. As a matter of fact, an inclination for the rails of 45° forms a very short or quick spiral indeed; while one of 60°, of course, is shorter still, and goes a very little distance along the circumference of the tank.

With regard to making exceedingly short spiral guides in alternate directions, as I explained at the meeting, I had experimented with such to a modified size. I had not shortened the spiral to the extent proposed by Mr. Livesey, although I confess I am at a loss to see how very short spiral or inclined guides—being a matter of degree only—can form a new invention after spiral guides in alternation, or whatever size, have once been employed for the same object. If a holder turns on its central axis, and at the same time is raised or lowered, it will take some kind of spiral motion; and *inclined* guides of some description must be used. Perhaps we shall see presently some person proposing to reduce the length of the inclined guides for alternate motion to a still greater extent, and thereby making a supposed departure from Mr. Livesey's proposal. On this head I may fall back on the old adage that, "Imitation is the sincerest form of flattery."

I see, by the letter which appears in this week's *JOURNAL* (p. 897), that Mr. H. E. Jones thinks there is extreme liability to jam when the holder is flattened by side wind pressure. I find it difficult to quite realize the precise meaning Mr. Jones wishes to put on the word "flattened." Of course, if the holder were flattened to the extent of producing a major diameter greater than the diameter of the tank, it certainly would jam; and so I opine would any gasholder. Has this ever occurred? Short of this catastrophe, general or local flattening—supposing such to be possible—would not interfere, provided the bottom ring remained, with the rise and fall of a holder constructed in accordance with my invention.

Mr. Jones has also a difficulty as to submergence of the rollers; but are not all bottom rollers submerged? Nevertheless, I can assure Mr.

Jones that my rollers are not very particular about adjustment; and an inch or so of play between the rollers and guides will not trouble a holder the least in its working or stability. If it be esteemed necessary to readily get at the rollers, they may be arranged round the top of the tank, free of the water altogether, as has already been shown.

So far as I can see, the sole legitimate doubt is that so fairly put forward by Mr. Cripps at the Southern Association meeting—viz., the resisting power of the holder to the distorting tendency of the transverse strains induced by wind pressure. On this head I hope shortly to be able to report the results of certain experiments actually made with the model, and also some others which will, I think, throw some light on the subject.

I am further hopeful it will not be very long before all concerned may be able to see a working holder on a practical scale, when the question will once for all be set at rest.

Manchester, Nov. 23, 1888.

W. GADD.

[The question of the accuracy of our comments upon the positions respectively occupied by Mr. Gadd's and Mr. Livesey's suggestions for guiding gasholders, must be decided by individual judgment. We can, however, and do distinctly repudiate the imputation in the second paragraph of the above letter, that in these comments we employed "the art of judicious tautology," with or without intent, to "create an unfavourable prejudice." We remain most deplorably ignorant of the existence of any "art of judicious tautology;" while pleading guilty to occasional indulgence in repetition of particular words, when the object is to emphasize a line of argument or to make an explanation specially clear. Mr. Gadd objects to our distinguishing his suggestion as a system of "long spirals;" yet he is fain to admit that Mr. Livesey's proposal is for "very short spiral or inclined guides"—much shorter, in fact, than he had ever attempted to make his own inclined tank guides. Where, then, is the error in our description of the difference between the two suggestions? We cannot profess to enlighten Mr. Gadd as to the degree of difference between two inventions, aiming at the same object, that may be legally held sufficient to constitute their independence. All that we can say is that we have tried to describe, for the benefit of our readers, what we have understood to be the obvious difference in the examples under notice; and if we have unwittingly done so in terms that displease Mr. Gadd, we are sorry for it, while still failing to see the heinousness of our language.—Ed. J.G.L.]

WATER BY MEASURE.

SIR,—“Positive” says that I have “not yet added anything to the discussion,” and he invites me to describe the meter on which my “conclusions,” as he correctly infers, “appear entirely to hinge.” The reasonableness of my position in basing my views on the merits of the meter is shown by “Positive” himself; for he says that his experience of low-pressure meters, is that they “are not so accurate as the present positive meters,” whilst all he can say of the latter is that he finds them “sufficiently accurate for all practical purposes.”

Previous to the enactment of the Act for regulating measures used in sales of gas, it was frequently said that gas-meters were “sufficiently accurate for all practical purposes;” but the Legislature brushed aside this vague expression, and prescribed the amount of error that would in future be allowed. This was declared to be 5 per cent.—2 per cent. in favour of the seller, and 3 per cent. in favour of the buyer; and we know that this has proved sufficient.

Now, if such a rule were applied to the water-meters “Positive” refers to, would they, one and all, or any of them, comply with it? If they would not, I, for one, would not consider them “sufficiently accurate for all practical purposes.” But, as has been rightly inferred, I have in view a meter which does comply with these conditions, and that too, under all possible variations as to quantity, between the full supply and the smallest drop. I shall therefore avail myself of your kind permission to send a description of this meter for an early number of the JOURNAL; and I am glad to learn from “Positive” that this will be “exceedingly interesting to all concerned.”

“Positive” says, “It is quite evident that ‘True Measure’ has not had experience, or he would not advocate meters at the end of a service;” and he adds that “gas men would not do that.” Now, is it not “Positive” whose “experience” is deficient? For do not “gas men,” in the majority of instances, do the very thing “Positive” says they “would not”? Is the gas-meter not, usually, placed at the end of the service? And has not the consumer full control of the pipes and fittings beyond it?

I may safely dismiss the suggestion of “Positive” that, with a meter on the end of the service—i.e., at the ball-valve of the cistern—pipes would be led from the service (behind the meter), and water would, through these, be stolen. There is no more reason to apprehend this in the case of water-meters than in the case of gas-meters; and whenever such a thing occurs in connection with the latter, gas companies know how to deal with it, and water companies would be no less equal to the occasion.

Nov. 23, 1888.

TRUE MEASURE.

A NEW WATER SCHEME FOR BARROW.—The General Purposes Committee of the Barrow Town Council have decided to promote in the next session of Parliament a Bill to empower the Corporation to take water from the River Duddon, and to construct weirs, settling ponds, conduits, &c. It is estimated that this work will cost £50,000. The reason the Corporation are promoting this Bill is because the Barrow Steel Company are requiring a further supply of water, which they are unable at present to obtain from the town's water supply; and, consequently, they propose to bring their own supply from the Duddon, unless the Corporation will agree to certain terms which at present are refused. Consequently, two separate schemes are being promoted for one object; but it is likely that a compromise will be effected, and that the supply will be provided by the Corporation.

Legal Intelligence.

HALIFAX BOROUGH COURT.—TUESDAY, NOV. 20.

(Before Mr. B. W. JACKSON and Mr. E. M. WAVELL.)

PROSECUTION OF THE LATE GAS-WORKS MANAGER.

This morning, Mr. William Carr, late Engineer and Manager of the Corporation gas undertaking was brought before the Court, having been arrested on a warrant issued at the instance of the municipal authorities. The warrant specified that “the said William Carr, then being Manager of the gas-works of a body corporate—to wit, the Halifax Corporation—unlawfully did, with intent to defraud, mutilate a certain book belonging to the said body corporate.”

The TOWN CLERK (Mr. Keighley Walton) appeared for the prosecution; Mr. WALTER STOREY defended.

The TOWN CLERK stated that the proceedings were taken under sec. 63 of the Act 24 and 25 Vict. cap. 96. He was not prepared to go into the case that morning, as Mr. Carr had only just been arrested; but he might state shortly that he would be charged with tearing out of a book belonging to the Corporation 79 pages. The pages contained very valuable information; and the absence of this information would prevent the Corporation from getting to the bottom of the “gas scandal.” He applied for a remand till the following Friday, and if necessary would call the Borough Accountant, Mr. Nichol.

Mr. STOREY (interrupting) said he did not object to the application at all. Mr. Carr, who had been in the South of England for a time, returned the previous Friday. He was in the town on Friday night, and had been about ever since. All sorts of rumours had been afloat—rumours that Mr. Carr was about to go to India, and other statements equally devoid of foundation. Mr. Carr was prepared to meet any charges preferred against him in the fullest manner at the proper time. He asked the Magistrates to fix bail; for there were many gentlemen in the town who had still confidence in Mr. Carr, and were ready to come forward as sureties.

Mr. WAVELL observed that the remand was only until Friday.

Mr. STOREY urged that the affair of the missing leaves was made public two months ago. Therefore, if Mr. Carr had wished to go away, he could have done so.

The TOWN CLERK said it was quite true that they knew about the missing leaves two months ago; but they did not until quite recently see the importance of the information which the leaves contained. Something had recently occurred of a very serious nature indeed, which rendered it most important that they should have these papers. They were more wishful to have the missing papers than that Mr. Carr should be punished.

Mr. WAVELL said the Bench as yet knew very little of the matter; but from what had been made public in the papers, the question as a whole was a very grave one indeed.

Mr. STOREY protested that statements in the newspapers ought not to influence the Bench.

The TOWN CLERK said he had no objection to bail.

The CHAIRMAN (Mr. Jackson) said that Mr. Wavell's remarks appeared to have been misunderstood by Mr. Storey.

After a short consultation, the Bench fixed bail—the accused in £500, and two sureties of £250 each.

FRIDAY, NOV. 23.

(Before Mr. E. M. WAVELL, Chairman, and Messrs. ARNOLD, WHITELEY, and HIGHLEY.)

MR. CARR COMMITTED FOR TRIAL.

Examination into the matter mentioned above was continued this morning.

Mr. BANKS, instructed by the Town Clerk (Mr. Keighley Walton), represented the Corporation; and Mr. McKEAND, instructed by Mr. Storey, appeared in defence.

Mr. BANKS, in opening the case, said he would state the facts very shortly. Mr. Carr was for some time Gas Manager to the Halifax Corporation; and on Sept. 28 last he was in possession of a copying-book which belonged to the Corporation. Some 79 pages of this book had been used for the purpose of copying gas tests; and on Sept. 28, the prisoner ordered a man named Milner—a clerk under him—to cut out the whole of these gas tests from the book. The following day, Carr left his situation. He (Mr. Banks) submitted that on these facts he should be entitled to ask their Worships to commit Mr. Carr on one or other of the two charges—or both—which he would quote. Under Vict. 24 and 25, cap. 96, sec. 83, he would submit that Mr. Carr did, being a public officer of a body corporate, mutilate a book belonging to that body corporate, with intent to defraud, although, of course, the question of intent to defraud was clearly a matter for a jury. The other section which he submitted would meet his case was the 67th section of the same statute, which set forth that any servant stealing a document should be guilty of a felony. As to the question of value, it was perfectly clear that the sheets had been taken; and if they were of no value, why should they have been torn out of the book? It was clear that they would have been of some value to the Corporation if they had been left there; and it was equally clear that they were of some value to the prisoner, who had taken them away. He would call the Borough Accountant to prove the ownership of the book; and then the clerk whom the prisoner instructed to remove the sheets.

Mr. James Nichol, Borough Accountant, said that he had held his present position for nearly thirteen years, and knew Mr. Carr as the late Gas Engineer and Manager to the Halifax Corporation. The foolscap copying-book produced was used at the gas-office, and was the property of the Halifax Corporation. The book was purchased in February, 1876, and had been in use since that time. He identified the letters produced, one from the Town Clerk asking for certain tests, and the other a reply from the prisoner informing the Town Clerk that he had not got the tests spoken of—that they had been submitted to the Committee, and he had not seen them since.

Cross-examined: The copying-book had been in Mr. Carr's possession from the time it was bought. He did not know that the book contained private analyses of coal made by Mr. Carr. There were 79 pages missing. He knew that Mr. Carr was allowed to make private analyses of coal submitted to him, unconnected with the Corporation altogether; and these private analyses would not have anything to do with the Corporation funds or with Corporation affairs.

Mr. J. Milner, Chief Clerk in the Corporation Gas Offices, deposed to having torn a number of leaves out of the copying-book, at Mr. Carr's request, on Sept. 28.

Mr. BANKS: What did Mr. Carr say to you?

Witness: He told me to take the coal tests out of the book.

Can you tell us how many pages you took out?—I cannot say. I was asked the question before; and I thought about 20 or 30, but could not tell.

Why did you select those sheets?—Because Mr. Carr told me.

Were those all the coal tests you could find?—Yes.

By the MAGISTRATES' CLERK: I gave the pages to Mr. Carr. As far as I can say, the book was intact before I commenced to take out the leaves.

Examination resumed, witness said that all the sheets he took out of the book were coal tests; and they were in his (witness's) own handwriting.

Mr. BANKS, at this point, said he would like to make one matter a little more clear. In a letter of the 28th of September last, Mr. Carr, in answer to a letter from the Town Clerk, asking him to forward the coal tests referred to in the report of June 1, said that he had not got them. On the following day the sheets were gone from the copying-book.

Cross-examined: Witness said he knew that Mr. Carr made private analyses; but he did not know that he did so with the consent of the Corporation. He found out after Mr. Carr had gone away that Mr. Berry, Alderman Midgley, and Alderman Riley were cognizant of his having made private tests. The surplus coal that was left after a private analysis had been made went to the Corporation.

Mr. M'KEAND: The pages which you tore out of the book related entirely, did they not, to private analyses?

Witness: I do not know, Sir.

What did he tell you to tear out of the book?—He told me to tear out the coal tests.

And you know that the coal tests you tore out were all private ones?—No, I do not.

There is one of the leaves (produced). As far as you know, it refers to a private analysis?—Yes, Sir.

Has it anything to do with Corporation business or funds?—The Corporation have never had any dealings with the person mentioned.

I will not put the whole of the sheets in; but only a few for the purposes of this cross-examination. That sheet marked "G" is also a private one?—Yes; this appears to be a private test.

Is the sheet marked "H" a private test?—Yes.

You used to copy these things?—Yes, Sir.

Did you ever yourself make a mess in copying these things, and have to tear a leaf out?—Yes, Sir.

Can you tell us, roughly speaking, how often you suppose that will have happened during the last twelve years?—I cannot say.

It might have happened eight or nine times?—It might; it is impossible to tell exactly.

You remember the tests referred to in the letter which has been mentioned?—Yes.

Had the tests referred to in the letter anything to do with the tests I produce to-day?—No.

Mr. M'KEAND (addressing the Bench) called attention to this last admission, and asked that it should be inserted in the depositions. Otherwise it would appear, from the letters, that the prisoner had told a deliberate falsehood.

The MAGISTRATES' CLERK said the Court was dealing with the question of mutilation. It would be for a jury to say whether there had been any fraudulent intent.

The CHAIRMAN said he took it that the duty of the Bench was to decide on the question of mutilation; and, if there were reasonable evidence, to then send the case on to another tribunal for further consideration.

Mr. BANKS: The witness was told to take out the coal tests, and he took out all the coal tests he could find.

The CHAIRMAN: He speaks to 20 or 30 sheets; while you refer to 79.

Mr. BANKS: That is his recollection of what he took out. I submit there is a strong presumption, which it is for the defendant to rebut, and which he must rebut before a jury. He is asked for the coal tests; and the very next day he tells this witness to take every coal test out of the book. Here is the book; and every coal test is gone. That is mutilation; and there is really no other inference to be drawn but fraudulent intent.

The CHAIRMAN: Do you propose to give any evidence as to the importance of these leaves?

Mr. BANKS said it would be some time before the trial came on, should the Bench choose to commit; and the interval would be spent by those who instructed him in strengthening the case in every way they could.

Mr. M'KEAND: You ought to do it to-day.

Mr. BANKS: Not necessarily. You shall have notice of all evidence in the usual way.

The CHAIRMAN asked the extent of the transactions which the missing sheets covered.

Mr. BANKS: Our discoveries are only very recent; but I believe the amounts are very large.

The CHAIRMAN suggested that it would have been the fairest course towards the defendant to have put in any general evidence which was in possession of the prosecution.

Mr. BANKS said the defendant should have notice of it as soon as possible.

Mr. M'KEAND: That is cruel.

Mr. BANKS submitted that the prosecution had made out a case of mutilation, and also of larceny.

Mr. M'KEAND said he believed that the rules observed at that Court would not allow him to go into the facts; but he would like to address a few observations to the Bench on points of law. He submitted that there was no case to go to a jury. His first argument might perhaps sound ridiculous at the outset; but he did not mean it to be so. He contended that there was no evidence of the existence of the Corporation of Halifax; and it was necessary, for the purpose of a criminal trial, that there should be a certificate of incorporation put in by a proper person to show that in fact the Corporation did exist. He had successfully upheld that objection over and over again; and he trusted that he should succeed once more. Apart from that, he had to urge that, unless they had some evidence to show that there was intent to defraud, there was no evidence to go to a jury. The inference drawn by the prosecution was that because the defendant had mutilated a book, therefore he had mutilated it with intent to defraud. But his friend was not in a position to call any witnesses to connect the transactions of the Corporation with the leaves which had been torn out; and this being so, there was absolutely no evidence of any intent to defraud. Mr. Carr was willing, and, indeed, he desired, to court the fullest investigation, because they had no fear of the issue, whether disposed of there or at the Assizes. He would be set right in the eyes of the public of Halifax, he was perfectly confident; but, under the circumstances, it was a cruel thing that a gentleman in his position should be kept waiting for his trial on such a serious charge. He (Mr. M'Keand) would wait the decision of the Bench with confidence, only observing that he could and would produce every one of the sheets about which complaint was made.

Mr. BANKS: That will be a question for the jury.

The Magistrates then retired for a few minutes; and on returning into Court,

The CHAIRMAN said they had decided to send the case for trial.

On being asked if he had anything to say, Mr. Carr intimated that he would reserve his defence.

Mr. M'KEAND: I suppose the Bench will allow Mr. Carr out on the same bail as before?

The CHAIRMAN: I should be glad if Mr. Banks could give me any idea, from general figures, of the amount of the transactions which these 79 sheets cover.

Mr. BANKS: It is almost impossible to say.

The CHAIRMAN: Is it tens of thousands?

Mr. BANKS: It may be; but that we cannot say. The amount must be very large.

The CHAIRMAN: The question of bail is always regulated by the circumstances of the case. In this case, as it is not opposed, the Bench will accept bail—Mr. Carr himself in £2000, and two sureties of £1000 each.

Mr. Carr was then formally committed to take his trial at the next Leeds Assizes.

At the close of the remaining business before the Bench,

Mr. STOREY said there were two or three gentlemen who would be willing to act as sureties for Mr. Carr, but only one was in Court. One was in Leeds, and another was in bed with rheumatism, but he was willing to attend as soon as possible. He (Mr. Storey) suggested that Mr. Carr should remain where he was until his sureties were able to attend. The latter would be men who would satisfy the Town Clerk and the Chief Constable.

The CHAIRMAN asked if it was not usual in such cases for the other side to concur in the bail offered.

Mr. STOREY said that was so; and he submitted that, the Chief Constable and the Town Clerk being satisfied, the rule was to allow the accused his liberty. To be sure, the Bench could make any rule they pleased.

The CHAIRMAN asked if it was not necessary that this should be done before a Justice.

Mr. STOREY said undoubtedly it was necessary; but any Justice would do.

The CHAIRMAN: You will, of course, take one who is not a member of the Town Council?

Mr. STOREY: Oh yes.

The CHIEF CONSTABLE said he thought it might be arranged during the afternoon or evening.

Among the witnesses said to have been subpoenaed by Mr. Carr, were Alderman Riley, Alderman Midgley, Mr. William Berry (three ex-Chairmen of the Gas Committee), and the Town Clerk; but as the defence was not entered upon they were not called. It is understood the three ex-Chairmen would have been called to show that it was customary for Gas Managers to be allowed to make private tests of coal.

Later in the afternoon, Mr. W. Longbottom and Mr. W. Swale offered themselves as sureties for Mr. Carr, and were accepted.

WESTMINSTER COUNTY COURT.—THURSDAY, NOV. 15.

(Before Mr. FRANCIS BAXLEY, Judge.)

THE GASLIGHT AND COKE COMPANY v. NORTHFIELD.

In this case, the point in dispute was as to whether or not it is necessary for a consumer to give notice in writing to the Company supplying him of his intention to discontinue the use of gas. The amount claimed by the Company was £1; being the value of gas consumed on the premises in question from April to August of this year.

Defendant stated that he left the premises referred to in 1880, and he informed the Company's collector of the fact. Since then the place had been let to two different tenants, whose names had been put up over the shop. He had been a customer of the Company for 40 years; and he believed he was doing what was right when he told the collector that he was leaving the place.

On behalf of the plaintiffs, it was pointed out that, under the Act of Parliament, it was necessary that notice to discontinue the supply of gas should be given to the Company in writing; and this was stated on the card which was left with each consumer.

His Honour, after referring to the Act, said that the defendant must pay the amount claimed—a written notice ought to have been given to the Company.

THE GASLIGHT AND COKE COMPANY v. HUSSEY.—A DEPOSIT QUESTION.

This was an action to recover £7 13s. 6d. from the defendant, who carries on business in Mare Street, Hackney, for gas consumed between Nov. 11, 1887, and June 19, 1888. The Company allowed £3 off this amount—being the sum paid by defendant as a deposit. The claim was admitted; but the defendant made a counter-claim for damage caused through the Company cutting off the supply without proper reason.

Mr. W. Barker stated that he made the contract on behalf of the Company to supply gas to the defendant's shop. He took £3 as deposit. The contract stated that the £3 would be deducted from "a" winter's quarter. A day or two before the contract was signed, he wrote a letter to the defendant, in which he said the deposit would "be returned on the winter's quarter." The word "the" was put in instead of "a" by mistake.

Defendant said that he forwarded to the Company the amount for the gas consumed, less the £3 paid as deposit; and it was returned. He sent it again; and it was returned. Soon after this the Company cut off the supply; and it caused him great inconvenience. He would not have signed the contract, unless the deposit was credited to him on the first quarter, as that was the winter quarter.

His Honour said it was clear that Barker had made a mistake in his letter, by writing the word "the" for "a;" and there must be a verdict for the plaintiffs on the claim and counter-claim.

FRIDAY, NOV. 16.

THE GASLIGHT AND COKE COMPANY v. LEACH.

In this case the amount sued for was £8; being for gas supplied to Messrs. Leach and Co., Wine Merchants, of Charterhouse Street.

On behalf of the Company, it was stated that the contract to supply the above-named firm with gas was entered into in 1878; and they held them liable for the gas consumed.

For the defence, it was alleged that in the year 1879 Mr. Leach left the firm, and gave notice to this effect to the Company; and the account now sued for was for gas consumed after his interest in the firm had ceased. When he left Charterhouse Street, he took offices in Fenchurch Street, and the Company supplied him with gas there; nothing being said as to the account at Charterhouse Street. He had never attempted to evade payment, because he did not consider he was liable; in fact, he knew nothing as to the amount of gas used after he left.

His Honour said he was not satisfied with the evidence; and he would therefore adjourn the case for the production of books and documents.

NEW RESERVOIR FOR THE HOBART WATER-WORKS (N.Z.).—The formal opening of the storage reservoir of the Hobart Corporation Water-Works, New Zealand, was celebrated a short time since. The reservoir, which was full to overflowing, contained 47 million gallons of water, which will be only drawn upon when the ordinary supply from Mount Wellington runs short. The cost of the work was £40,000.

Miscellaneous News.

SALFORD CORPORATION GAS SUPPLY.

THE HUNTER CASE.—THE GAS COMMITTEE AND THE PRESS.—MR. ELLIS LEVER'S CHARGES AGAINST THE DEPARTMENT.

At the Adjourned Quarterly Meeting of the Salford Town Council last Wednesday—the Mayor (Mr. Alderman A. L. Dickens) presiding—the above-named matters were under consideration.

Mr. LORD, Chairman of the Gas Committee, moved—"That, as recommended by the General Purposes Committee, a previous resolution appointing eight members of the Council to form a Consultative Committee in relation to the matters pending in connection with the Hunter case be rescinded, and that the Mayor and four members of the Council form the Committee."

Alderman HALL seconded the motion.

Mr. RYCKOFF proposed an amendment to the effect that the Committee consist of six members of the Council and the Mayor *ex officio*. He remarked that the Committee being a General Committee, it could not legally be composed in the manner suggested. Each district of the Council, he maintained, ought to have an equal representation on such a Committee. His object in moving the amendment was that Mr. Hewitt and himself might be placed on the Committee. When the Investigation Committee was being dissolved, he desired to be placed on the Consultative Committee; and the Investigation Committee in the first instance nominated Mr. Hewitt and himself as members of the Committee. But—under the influence of the late Town Clerk, he believed—Mr. Hewitt, himself, and Mr. Mandley were excluded from the Committee. However, he did not complain of the past. As the questions which would come before the Committee involved legal points, he thought Mr. Hewitt and himself, being members of the legal profession, ought to be on the Committee, so that they might give as much assistance as they could to the Committee and to the Town Clerk. In the past the Consultative Committee had been oblivious to what was going on; and were only called together when it suited the late Town Clerk. He wished to have a Consultative Committee which would endeavour to understand the position of matters, and do its work promptly, and with decision.

The Mayor assured the Council that it was desirable that things should be done quietly, and that the Committee should be as small as possible. Information had been conveyed to him since the last Consultative Committee meeting, which showed him very clearly that the result of the appointment of a large Committee would simply be to undo the work that was being done. The important information which would by-and-by be placed before the Council would show that the Committee had done its work.

Mr. DAVIS seconded the amendment.

After a short discussion, the vote was taken, when 26 were in favour of the amendment and 21 against. The amendment was then put as a substantive resolution, and adopted.

The Council then appointed the Committee "in relation to the matters pending in the civil action against Samuel Hunter;" and they were authorized "to take such legal or other proceedings as they may think fit in all matters that may arise in such action or actions, reporting from time to time their proceedings to this Council." The Committee consists of Alderman Husband, Mr. Phillips, Alderman McKerrow, Mr. Hewitt, Alderman Walmsley, and Mr. Ryckoff.

In reply to a question, it was stated that the Committee would have power to start an action against a coal contractor.

Mr. RUSSELL next moved—"That inasmuch as it is desirable that the ratepayers should know more about the Council proceedings, the General Gas Committee be and is hereby instructed to admit to their General Committee meetings the responsible representatives of the local and district press, on the understanding that it be in the power of a majority of the members then present to declare any matter before them to be private, and to consider the same during or without the presence of the reporters as they may see fit." He considered the time had arrived when something ought to be done in the direction he had indicated. Past affairs connected with the gas-works had occupied a good deal of attention lately; and he thought that it was desirable they should attend still more closely to present affairs. He believed the ratepayers wished for, and were entitled to more information than they had at present with regard to the work of the Gas Department. With more publicity, the members of the Committee would receive greater credit for, and more support in their work than they did just now. Rightly or wrongly, Salford was under a cloud, and the Gas Department in particular; and he believed publicity would do much to clear away this cloud. With regard to recent proceedings connected with coal contracts, with the question of stokers' wages, and other matters, publicity would have saved a good deal of misapprehension.

Mr. RUDMAN seconded the motion.

Alderman BROWN observed that, while Mr. Russell had put the matter in a fair and reasonable way, in his opinion, a wiser plan than that proposed would be for each Committee to take its own special circumstances into consideration, and decide for or against reporters being present. He moved, as an amendment, that the matter be referred to the Gas Committee for consideration.

Alderman MCKERROW, in seconding the amendment, said they had had experience of the presence of reporters at meetings of the other Committees of the Corporation. He did not say that any serious mischief had arisen from it; but he certainly felt that any advantage there had been connected with the opening of the Committees had been counterbalanced by the inconvenience which had been occasioned. He thought that of all the Committees of the Corporation, the one that was most likely to have delicate matters to negotiate—such matters, for instance, as the coal contracts and the selling of the bye-products—was the Gas Committee; and this being so, he thought Mr. Brown's proposal was a reasonable one. As a matter of policy, he thought it was inexpedient to admit reporters.

Mr. ROGER supported the amendment, and expressed a hope that the Gas Committee would decide to adopt the proposal in the resolution.

Mr. LORD said he was not unwilling that the question should come before the Gas Committee; but personally he agreed with Alderman McKerrow that as a matter of expediency, and in the interests of the ratepayers, it was better their proceedings should not be reported.

The amendment was adopted.

Mr. PHILLIPS subsequently said he desired to know whether any further communication had taken place with Mr. Ellis Lever with the view of obtaining from him the information which, in his letter to the local papers, he offered to communicate to a Committee. On Oct. 31, the Council adopted a resolution he proposed, accepting Mr. Lever's offer; but Mr. Lever had refused to go on because of certain statements with which the resolution was weighted—because of the Mayor's declaration that he would take care to be present, and that there would be shorthand notes taken of all that took place. He thought it was most desirable to

get to the bottom of the statements which had been made by Mr. Lever; and this being so, he wished to know whether the Mayor and the Council would not accept Mr. Lever's terms pure and simple, and allow him to make his communication to the three gentlemen who might be appointed.

The Mayor said he would be prepared to agree with Mr. Lever to the extent of dispensing with the shorthand writer; but if Mr. Lever met the Committee in the Town Hall, he would insist upon his right as Mayor to be present.

Alderman WALMSLEY hoped the Mayor would be present at any meeting of the Committee appointed.

The Mayor observed that if the persons chosen met outside the Town Hall, the matter would be different; but if they met there, he must be present.

It was then resolved, on the motion of Mr. RUDMAN, seconded by Mr. ROBINSON, to accept Mr. Lever's terms unconditionally.

THE BLYTH GAS COMPANY AND THE COWPEN LOCAL BOARD.

THE PUBLIC LIGHTING QUESTION.

In the JOURNAL for the 6th inst. (page 815), we briefly noticed an extraordinary meeting of the Blyth Gas Company, which had been convened for the purpose of considering the dispute that has arisen between the Directors and the Cowpen Local Board. A resolution was then passed, to the effect that an offer should be made to the Board to elect three of their number to meet an equal number appointed by the shareholders of the Company to discuss the matters at issue between the two bodies. At the succeeding meeting of the Local Board, the Clerk read two letters from the Gas Company, in which it was stated that they had appointed Messrs. Lynn, Walker, and Keenlyside as a deputation to meet a Committee of the Board. He also announced that these three gentlemen were in attendance. It was agreed to at once hear the statement of the deputation. On entering, Mr. Lynn (speaking on behalf of himself and his two colleagues) briefly referred to the proceedings at the meeting of the Company at which they were appointed to discuss the matters in dispute with a Committee of the Board; but to save time the deputation had decided to wait upon the Board that day. He had to ask them to re-open the negotiations which had been so abruptly closed; and he was sure that if they were inclined—and he did not anticipate any difficulty—they could bring the matter to a satisfactory termination. The unfortunate dispute, he believed, first arose with regard to the purchase of the lamps; and he found in the report of the Board's meeting that there was an offer made by the Board's Committee of 30s. per lamp all round. This offer the Company then refused. To show, however, that they were now prepared to waive everything they possibly could, and to avoid any question of arbitration, they would sell them at the Board's own price. He thought that this was as far as they could go in the first instance. In the discussion which ensued, the Chairman (Mr. W. Robinson) said that the whole of the ratepayers were against buying the lamps; and he thought the only thing which would meet the case would be a reduction in the price of gas, and a cheap rate for the public lighting during the remainder of the season. To this Mr. Lynn replied that the Company had very carefully considered the lighting of the district for the remainder of the season; and they had arrived at a lump sum, which was the lowest they could possibly do it for. At the meeting of the shareholders, he understood that there was no dispute as to the price of the gas; but he would take it upon himself, on behalf of the shareholders, to say that they would supply the Board with gas at 15 per cent. below the ordinary price. Certain members of the Board said that they should object to this arrangement, unless some concession was also made to the consumers. After further discussion, Mr. Lynn expressed the willingness of the Company to light the district for the remainder of the lighting season—from Nov. 22 to May 15 next—for £258 net; but he was not prepared to say that the Company would afterwards continue on these terms. The Chairman promised that the suggestions of the deputation should be considered; and the members then withdrew. A representative of Messrs. Jeunings and Co., electricians, of London, then had an interview with the Board. He said they were prepared to light the town for £600 a year; he gave it as his opinion that 18 electric lamps would suffice. The shortest period for which his Company would tender was seven years.

An Adjourned Meeting of the Local Board was held on the 13th inst.—the CHAIRMAN (Mr. W. Robinson) presiding—to consider the matters referred to above. A communication was read from the deputation of the Gas Company, offering to light the district from Nov. 22 to May 15 next for the sum of £258.

Mr. HEDLEY thought the time was come when they should adopt some mode of lighting the district. They had been in darkness too long; and he believed it was owing to the high price the Gas Company had been charging for their gas. The fact was apparent that other lights could be had more cheaply. He thought there would be improvements in electric lighting; and it would be wise for the Board only to have it for a short time, so that they might probably get better terms with the electric light company which they had been in treaty with for some time. He considered, if the electric light was adopted, it would be to the benefit of the community, and might tend to increase the consumption of gas for other purposes than those which it had been hitherto used for. He moved that the Board adopt the electric light for lighting the district.

Mr. TODD said if Mr. Hedley would move that they should accept the tender of the electric lighting company, he would second it.

Mr. HEDLEY consented to do this.

Mr. TODD seconded the motion. The residents in the district, he said, had been very patient; and he thought that that night the Board should come to some definite conclusion. He believed electricity would be the cheapest illuminant in the long run. This might be questioned; but he pointed to the £390 which gas would cost without the plant, and they would require 50 other lamps if they took Cowpen Colliery into the lighting area. Altogether it would cost about £550. He supported the idea of electricity, on the ground that it was the unanimous wish of the ratepayers that they should have the electric light, and crush the monopoly with which they had been for so many years contending.

Mr. JOBLING desired to point out what he conceived to be the greatest drawback to the adoption of electricity, and that was the seven years' agreement. By it they shut themselves out of all improvement, which they should be careful to watch. If they could by any means reduce the period to a shorter one—say, three years—it would be better for them.

Mr. NIXON suggested that they should try and get better terms for the electric light.

Mr. LEE said he went down one of the back streets during the exhibition of the electric light; and he certainly was not satisfied. He thought the back streets were the most important parts of the town. He also took exception to the seven years' contract, as it was a long time to be tied down. He should like to ascertain whether they could not have the district lighted with oil-lamps.

Mr. HINDMARCH considered that a four years' contract would be more reasonable.

On the motion being put to the vote, it was negatived by 5 votes to 3. Mr. NIXON then moved that a Committee be appointed to confer with the electric light company, to see whether a shorter term than seven years could not be arranged for a contract.

The words, "and with the gas and oil companies" having been inserted, the motion was carried.

It was decided that the Clerk should acknowledge the receipt of the letter from the deputation of the Gas Company, and inform them that it was not satisfactory, and that they could not entertain it.

At a Special Meeting of the Local Board, held last Wednesday—the CHAIRMAN (Mr. W. Robinson) presiding—the public lighting question was again under consideration.

The CHAIRMAN reported that the Committee appointed at the last meeting of the Board had fully considered the subject of public lighting, and had come to the conclusion to recommend the Board to make an offer to Messrs. Nicholson and Jennings. They were to be asked to supply electricity at the rate of £550 per lighting season for 18 arc lamps of 2000-candle power, for a period of five years, subject to conditions and arrangements to be mutually agreed upon; the work to be satisfactorily completed within a period of two months from the date of signing the contract.

Mr. BRYSON inquired whether any counter-proposals had been received from the Gas Company.

The CLERK said they had not. He had had a letter from Mr. Lynn, acknowledging the receipt of the communication which he (the Clerk) was instructed to send him, and expressing regret that the Board could not see their way clear to accept the offer made by the deputation on behalf of the Gas Company, so that the town might be lighted pending negotiations.

Mr. LEE said he thought it was a pity the Gas Company could not see their way to offer terms for three years which might have met with the Board's acceptance.

Mr. TODD moved that the recommendation of the Committee be adopted. Mr. HEDLEY seconded the motion.

Mr. WHITEMAN proposed that the words, "Further, that all arrangements and sanctions necessary from the Board of Trade be obtained by contractors," be added to the recommendation of the Committee.

This proposal having been agreed to, the Committee's recommendation was unanimously adopted.

One of the local papers reports that the Gas Company are removing their lamps and placing them in store; and this action, it says, puts "an element of uncertainty out of the way, it reissues the Company in a position of dignity and self-respect, and is a virtual intimation to the Board that it is at liberty to proceed with its alternative method of lighting."

MOSSLEY CORPORATION GAS SUPPLY.

AUDITOR'S REPORT.—THE LEAKAGE.

At the Meeting of the Mossley Town Council on Thursday, the 15th inst., the Mayor (Mr. Alderman R. S. Buckley) presiding, the Auditors presented a report on the gas accounts for the half year ending Sept. 29 last, in the course of which they stated as follows:—

The total make of gas during the half year, according to the Manager's report, has been 19,704,900 cubic feet. The sales have been as under:—

	Mossley. Cubic Feet.	Saddleworth. Cubic Feet.	Total. Cubic Feet.
Private consumers	7,721,300	5,587,800	13,309,100
Public lamps	705,100	59,200	764,300
Used on works	258,200	—	258,200
Total	8,684,600	5,647,000	14,331,600

leaving a balance unaccounted for of 5,373,300 cubic feet, or 27·27 per cent. on the total make. For the corresponding half year in 1887, the loss or balance unaccounted for was 26·86 per cent. We have before remarked that this loss is exceptionally heavy; and we still think that it requires very careful attention. The following is a comparison of the amounts charged for gas (inclusive of lamps and works) for the corresponding periods of 1886, 1887, and 1888:—

	Half Year ending Sept. 3.		
	1888.	1887.	1886.
Mossley	£1221 4 7	£1193 15 4	£1308 4 10
Saddleworth.	848 9 8	893 9 4	881 5 4
	£2069 14 3	£2077 4 8	£2189 10 2

Although the amount for September, 1888, is slightly less in comparison with September, 1887, there is an actual increase in the consumption of gas—the relative quantities, in cubic feet, being 14,331,600 and 12,926,600; the difference in value arising from the reduction of 4d. per 1000 cubic feet from March 25 last. The arrears of gas-rentals at Sept. 29 amount to £96 16s. 10d., of which £11 8s. 4d. has since been written off as irrecoverable. This compares very favourably with the state of the arrears in September, 1887, when the amount was £227 2s. 11d. New mains have been charged during the half year with £136 3s., being the proportion of the Staveley Coal and Iron Company's invoices of £301 10s., and representing the difference in the cost of the 10-inch, as compared with the 6-inch mains for which they have been substituted in the Saddleworth district.

The Mayor, referring to the increase in the leakage, said it was not more than they expected, because there naturally was a considerable amount of gas lost during the laying of mains. The result of the experiment of putting down larger pipes in Saddleworth had yet to be proved; but it was expected that its effect would be to much reduce the leakage. They were already supplying gas to Saddleworth at lower pressure than at the same time last year, and they were hoping that the leakage would be proportionately reduced. If this did not result, they would have to adopt other and more decided means to reduce it. Of course, it was only during the summer months that it was so heavy. It was not probably half the amount during the winter. Still, unless the leakage was reduced, the anticipations of the Chairman of the Gas Committee this year would not be realized. With respect to the income from the supply of gas, there was one pleasing feature. In 1887 the total receipts from March 25 to Sept. 30 were £2077; and this year they were £2069—a difference of only £8, though during the interval the price had been reduced 4d. per 1000 cubic feet. He thought this a matter for congratulation.

Mr. MARLAND asked if the consumption at the works was registered. They put it down at £48; and he wished to know the basis on which this was calculated.

Mr. J. MAYALL thought the Gas Manager should be instructed to check the consumption in different parts of the district, both Mossley and Saddleworth. It was impossible for 26 per cent. of gas to escape; and it seemed to him it was being consumed without being paid for.

The Mayor said, with regard to the registration of the gas at the works, that Mr. Marland was a member of the Gas Committee, and if the meter was there he should see it. Mr. Mayall was also on the Committee. The point he had mentioned was one that had occupied his (the Mayor's)

attention very seriously. Eighteen months ago he would have called in an expert to ask his opinion as to the loss of gas. It had been in the hands of the Committee, and they decided to put down new and larger mains, and see whether or not they could reduce the waste. They must try this now; but he would have resorted to stronger measures.

THE LONDON COAL DUES.

THE DIVISION OF THIS YEAR'S SURPLUS.

In the course of a long letter, a correspondent of *The Times* last week discussed the subject of the distribution of the present year's surplus of the London Coal Dues. He commenced by pointing out that the Metropolitan Board of Works are not entitled to receive the duties collected in respect of coal brought into London since July 5 last, although the duties remain to be payable till the corresponding date next year. The continuing Act of 1868 specifies that, in the event of there being a surplus, the same is to be applied "as Parliament may hereafter direct." Speculation is already rife as to how Parliament will "direct," and already, as will be seen later on, suggestions have been made as to suitable objects on which to bestow the remaining funds. The duties produce annually about £450,000; and according to a statement prepared and issued last year by the Metropolitan Board of Works, the cost of freeing the bridges—the main purpose of the dues—amounted to £353,618. Consequently, there will be about £100,000 to dispose of, which amount will probably be available somewhere about September next. Any disposition concerning it must, therefore, be made next session. In view of this state of things, two notices have already appeared in which claims are put forward to some portion of the dues. Under one of them it is proposed to apply for an Act to appoint trustees to take charge of the surplus of the London coal and wine dues, and to apply the same, "together with any other moneys that may come to their hands by gift or otherwise," as follows:—"In the purchase of lands, rights, and easements, and for providing the expenses of erecting a monumental chapel or other buildings, in proximity of, or contiguous to Westminster Abbey; the preservation of open spaces within or near to the Metropolis; and generally to apply such surplus, or portion thereof and other moneys in or towards one-half the expenses of such monumental chapel, and other works, public buildings, and improvements within the Metropolis, as defined by the Metropolis Management Act, 1855, or within the area of the Metropolitan Police district, or such objects as will be named in the Bill, or as Parliament shall direct; the other one-half part of the expenses to be incurred in or about such works, public buildings, and improvements being provided from other sources." A second and independent notice contemplates an Act to authorize certain lands and houses at Westminster being purchased, by compulsion if necessary. It is proposed to remove the houses situated in Old Palace-Yard "for the purpose of opening out a view of Westminster Abbey, the Chapter House, and other buildings, and to appropriate a portion of the site so cleared for the erection of a monumental chapel in connection with Westminster Abbey, and in the improvement of the approaches to the Abbey." To aid in effecting these objects it appears to be intended to ask the sanction of Parliament to apply the whole or some part of the surplus coal duties for the present year. These notices, it was remarked, "foreshadow a regular scramble."

Proceeding to explain how the dues are raised, the writer observed that, as is well known, the whole of the Metropolitan Police District contributes to them. This district extends far beyond the Metropolis, and comprises Cheshunt on one side of London and Epsom on the other. "It is not likely," he said, "that the Local Authorities of the extra-Metropolitan district will very quietly stand by and see the surplus duties of the present year appropriated to improvements in Westminster. It is true that the toll bridges which are freed by the present year's duties are not bridges which afford much convenience to the City or to the Westminster ratepayers; but on the other hand, the coal consumers in the extra-Metropolitan districts have for many years contributed to the duties which have been exclusively laid out within the Metropolis. It may, at any rate, be fairly argued that, as the Legislature only gave the Metropolitan Board of Works the coal duties up to the 5th of July, 1888, and then partially appropriated the duties for the following year, it was considered that the Metropolis had received all the benefit it was entitled to from the coal duties levied for a great number of years over a large outside area. Another question may arise in connection with this surplus. The Act of 1868 is not very clearly drawn; and it will be open to the Corporation of the City to urge that the surplus wholly belongs to them. Their right to this depends upon the construction of the Act of 1868 and preceding enactments. Although, however, the question of interpretation may be discussed, there can be little doubt that Parliament will consider that it is able to exercise the power, which in 1868 it reserved to itself, of dealing with the surplus as it should 'hereafter direct.' When, in the early part of the present year, the Metropolitan Board and City Corporation offered the Local Authorities of the outside area a tempting bait if only they would help them in getting the coal duties re-imposed, a statement was published by the Corporation of the City indicating what, in the judgment of the Corporation, was a fair proportion of the duties to be repaid to the Local Authorities in the non-represented area."

The net amount produced by the coal duties being £450,000, as collected for a year from a district having a net rateable value of £38,000,000, it was estimated that the amount collected in the area outside the Metropolis was, in proportion to rateable value, equal to about £85,000. Dividing the assumed surplus of £100,000 on a similar basis, the Metropolis would be entitled to about £78,000 and the outside districts to about £22,000. Worked out on the same principle, the writer considered that the following counties would be entitled to the amounts named:—Middlesex, £9410; Surrey, £5720; Essex, £4410; Kent, £1810; Herts, £650. He thought, however, that the districts comprised in these counties had a claim to a much larger sum (£100,000 was named), divided in similar proportions to the £22,000 mentioned above.

ROSARIO WATER COMPANY, LIMITED.—The ordinary general meeting of this Company was held on Monday last week, at Winchester House, Old Broad Street—Mr. J. Morris in the chair. The report stated that the gross revenue from the opening of the works on Aug. 1, 1887, to June 30 last had been £7776, and the expenses £4858; leaving a balance of £2918, which had been carried to the credit of net revenue account. After charging that account with the debenture interest and interest on loans for the year ended June 30 last, there remained a balance at the debit of the account of £5195. Last December a concession was granted by the Municipality for the drainage of the city, one of the terms of which was that the taking of the Company's water was obligatory on all the houses connected with the drainage system. An English Company had been formed for carrying out this concession; and the works, which were being proceeded with, were expected to be completed within two years. The Chairman, in moving the adoption of the report, referred with satisfaction to the progress of the undertaking, which he believed had a bright future before it. The motion was adopted.

BAHIA GAS COMPANY, LIMITED.

The Half-Yearly General Meeting of this Company was held last Thursday, at the London Offices, No. 7 and 8, Idol Lane, E.C.—Mr. E. HORNER in the chair.

The SECRETARY (Mr. A. J. Head) read the notice convening the meeting; and it was agreed to take as read the Directors' report and the statement of accounts for the half year ending June 30 last, which were summarized in the JOURNAL for Nov. 13 (p. 851).

The CHAIRMAN said that the first resolution he had to put before the shareholders was—"That the report and statement of accounts now presented be and is hereby adopted." In proposing this, he did not think there was a great deal for him to say. He had carefully gone through the figures in the accounts; and he made out that there were certain items in them on the expenditure side which had, taking them together, risen to £618 more than in the previous half year. On the other hand, there were decreases which amounted in all to £1090; leaving a considerable balance in favour of the Company. One of the principal causes of this result was the rate of exchange, which, fortunately for the Company, had gone up very much. They were £687 better off in this respect in the present half year than before. On the other side of the account, there were items that showed a decrease together of £189; while the other items exhibited an increase of £588. This result was very satisfactory. There was no doubt about the fact that exchange had gone up at last; and he hoped, looking at the low rate of interest which now prevailed in the country in which they carried on their operations, that it would not be so bad again as it had been. The gas made during the half year had been scarcely so much per ton of coal carbonized as previously. This was due to the fact that they had been using up the stock which had been on the works a long time. Of course, in a hot climate, the coal, if kept in stock a certain time, would not yield so large a quantity of gas as when fresh. They were now using a new lot of coal, and they were producing quite as much gas per ton as formerly. In conclusion, he remarked that the Board hoped to be able to meet the shareholders on future occasions in just as happy a position as on the present.

Mr. HORATIO BROTHERS seconded the motion.

Mr. MACHELL asked the amount of the unaccounted-for gas, as he did not see it mentioned in the report. At the last meeting, this matter was referred to; and it was stated that the leakage was largely caused by the traffic and the opening up of the ground in Bahia, which greatly injured the pipes.

The CHAIRMAN said that the leakage in the previous accounts was 9·6 per cent.; and on the present occasion it was 10·1 per cent.

Sir H. E. CARTWRIGHT inquired whether the Directors had been able to sell any of the Bahia provincial bonds since last year. A certain number appeared in the accounts; and he was aware that there was at present an impression that bonds of this sort were not so saleable as they were some time ago. There was some expressed fear as to the uncertainty in Brazilian politics just now. For his own part, however, he believed the bonds were good.

The CHAIRMAN said they had sold £3800 of the provincial bonds during the half year. They could have disposed of more; but they did not care to do so.

Mr. J. W. MASON said that at one of the previous meetings a question was asked as to the large amount of preliminary expenses which was standing in the balance-sheet of £10,000. The reason given, he recollected, as to why this particular item was kept in the accounts was that it might influence the position when the Company was taken over, or the concession that would be moved for by-and-by. In the present accounts he noticed that £8000 of this amount had gone somewhere since the last meeting; and he should like a little information respecting this point.

The CHAIRMAN observed that this matter referred to a time prior to his connection with the Company; and he would ask Mr. King to explain the matter.

Mr. A. J. KING said it was true that the item alluded to stood in the previous accounts at £10,000. The original estimate of preliminary expenses was £16,914; and this had been partly written off by successive sums of £1000 from revenue account since 1880 till now. The reason of the £8000 disappearing now was this: It seemed a very extraordinary thing that, after 28 years' existence of the Company, it should have any preliminary expenses at all; and the Board asked the Accountant to prepare an analysis of the balance still remaining of those expenses, and say whether it was all properly chargeable as such. He reported that no less than £8000 should be charged as investment; and the Board had carried this sum to investment—leaving only the balance of £2000, which would disappear in due course by successive half-yearly amounts. He thought they were perfectly justified in dealing with the £8000 in this manner.

Mr. MASON said that, to his mind, it had taken a long time to come to the conclusion that this sum should have been charged to another account. If care had been taken in working out the accounts originally, this amount would not have appeared so long in the balance-sheet.

Mr. KING remarked that the present Board inherited the accounts from their predecessors.

The motion was then agreed to.

The CHAIRMAN moved the declaration of a dividend for the half year ending June 30 last at the rate of 10 per cent. per annum, less income-tax, on the 10 per cent. preference capital, of 7½ per cent., less income-tax, on the 7½ per cent. capital, and of 10 per cent., free of income-tax, on the ordinary capital of the Company.

Mr. MACHELL seconded the motion, which was carried unanimously.

On the motion of Mr. BROTHERS, seconded by Mr. A. M. CLARKE, Mr. Horner was re-elected to his seat at the Board; as was also Mr. A. J. KING, on the motion of Mr. H. FINLAY, seconded by Mr. CLARKE.

The CHAIRMAN and Mr. KING having acknowledged their re-election,

Mr. T. GUYATT proposed, and Mr. ESCOTT seconded, the re-election of the Auditor retiring by rotation (Mr. Magnus Ohren, Assoc. M. Inst. C.E.). The proposition having been agreed to,

The CHAIRMAN moved a vote of thanks to the Superintendent (Mr. F. Hooper), the Secretary, and the other officers of the Company.

Mr. BROTHERS seconded the resolution, which was heartily approved of. Sir H. E. CARTWRIGHT said that the shareholders were indebted to the Directors for the successful working of the past half year. It had been a fairly difficult position; and he hoped that the Board would work on with the same success in the future. He suggested that the Directors should use proper influence in the necessary quarters, and forestall any arrangement that might be made as to the continuation of the concession. This was a serious matter that the Board had in hand; and they would have to exert every possible influence they had in all quarters, so as to ensure the future success of the Company. He concluded by proposing a vote of thanks to the Chairman and Directors.

Mr. MACHELL seconded the motion, which was agreed to *nem. con.*

The CHAIRMAN thanked the shareholders for their recognition of the Directors' services. Referring to the question of the concession, he said that there was a large gas company working in Europe whose concession lately expired; and they had done what he should like to see carried out—that is, have an interminable concession. They would be able to put such

a case before the Government or the Corporation of the town as would give them an immediate profit, so that they would never terminate with the Company at all. Even if the shareholders took a little less dividend and succeeded in this way, it would be of permanent interest to the Company.

The proceedings then terminated.

THE AFFAIRS OF THE QUEENSTOWN GAS COMPANY.

The Auditor appointed by the Queenstown Commissioners (Mr. M. P. Buckley) to investigate the accounts of the Queenstown Gas Company has presented his report, dealing with the accounts for the year ending June 30 last. He says the quantity of coal carbonized in this period was 1530 tons 18 cwt., which cost £1038; or an average of 13s. 6½d. per ton. The total make of gas was 14,394,000 cubic feet; being equal to a production of 9400 cubic feet per ton of coal; and the loss by leakage was 1,914,400 cubic feet, or 13·35 per cent. The working expenses for the year were £2429 4s.; and the total receipts amounted to £3939 3s. 10d. The outlay on the Company's permanent investment, which now stands at £19,794 4s., was £11 12s.; while the paid-up share capital and debentures is only £19,672 16s. 11d.—thus showing an outlay of £125 8s. 1d. on capital out of revenue. The result of the year's working shows a profit balance of £1509 19s. 10d., which is allocated as follows:—Debenture interest, £209 13s. 3d.; dividend at the rate of 6½ per cent. on "A" shares; 3½ per cent. on "B" shares; 4½ per cent. on "C" shares—in all £815 8s.—and depreciation £80; leaving a surplus of £404 5s. 4d. Mr. Buckley says that if the shareholders had received their usual full statutory dividend of £1247, instead of £815 18s., and the Directors and Auditors their usual fees of £115, the year's working would show a deficit of £142 6s. 8d. The surplus assets of the Company now stand at £248 12s. 8d., as compared with £2916 1s. 3d. for the corresponding period of 1887. In other words, the surplus assets of the Company are now less by £3071 13s. 11d. Since the last audit, certain defalcations, amounting to £991 13s. 11d., occurred in the office, owing to a system of fraud carried out by the former Secretary through the medium of the rental journal. Mr. Buckley shows how this was effected. Supposing a consumer owed £7 10s., and paid his bill in due course, the Secretary (who was also Cashier and Collector) appropriated the amount and allowed the sum named to stand in the books as against the consumer. He explains that all the books were certified as correct before he commenced his annual audit; and he therefore concluded that the balance brought down at the foot of each consumer's account was strictly accurate. He also mentions, in justification of the Company's Auditors, that the skilful manner in which the frauds were effected almost prevented detection. He confesses that he attributes this loss to the false economy practised by the Directors in entrusting the duties of Secretary, Collector, and Cashier to one individual, and not having ample security with a person occupying a position of such responsibility. Mr. Buckley takes exception to the allocation of £2150 among the shareholders of the old Company, with the sanction of the Master of the Rolls. This sum is composed of two items; £1593 18s. 11d., being surplus assets as shown by the balance sheet of 1879; and £556 1s. 1d., interest allowed thereon from this period up to June 29, 1888. As regards the item of interest, he finds that the sum of £1593 18s. 11d. realized to the Company during the nine years only £419 1s. 4d., yet £556 1s. 1d. has been paid to the shareholders of the old Company—showing a loss of £136 19s. 9d. On this subject Mr. Buckley remarks: "I am of opinion that the Directors of the new Company should have calculated on the actual amount of assets realized, and they certainly ought to have been satisfied with the amount of interest accrued thereon, as it was they who invested the money, and consequently they ought, to say the least of it, to be content with the result of their own investment. Now, what is the fact? £153 15s. 7d. of the amount put down as surplus assets was never realized; and not only did they receive this amount, to which they had no claim, but they were actually paid 4 per cent. per annum interest on it for nine years. I may mention that the 1000 shares of the old Company in 1879 were held by 35 shareholders, 23 of whom have retained 822 of them and since considerably added to this number; so that in point of proprietary, the old and new Company are, with few exceptions, virtually one. As your Auditor, I have done all I could to prevent what I considered misappropriation of the Company's assets, as I respectfully submit the Legislature never contemplated such allocation of them when granting the Queenstown Gas Act of 1879; and I am still of opinion that my contention is based upon equity and common sense." Accompanying Mr. Buckley's report is a copy of the "opinion" of Mr. J. Atkinson, of Dublin, to the effect that the profits of the old Company do not properly form part of the reserve fund, but under the 7th section of the Queenstown Gas and Light Act, 1879, are assets to be applied to the purposes of the Company.

THE PUBLIC LIGHTING OF BUTTERSHAW.—At the meeting of the Buttershaw Local Board last Thursday, it was reported, on behalf of the Gas Committee, that trial had been given to several types of oil-lamps for street lighting purposes, but none had proved satisfactory. In the point of cost, too, they found there would be no economy in working expenses as compared with gas, and there would have to be a large outlay in the purchase of the new oil-lamps. In this condition of affairs, the members were of opinion that oil lighting could not be entertained at all; neither could the Board, in face of the expressed opinion of the ratepayers, take steps to light the existing gas-lamps. It was therefore decided to take no further action in the matter of the public lighting of the place.

THE LIVERPOOL CORPORATION AND THEIR "WATER FAMINE" RATES.—Last Wednesday, at the County Magistrates Court, the Liverpool Corporation sued a Solicitor (Mr. W. Cowl) for a sum of £1 for "garden water" supplied during the past summer. It seems that early in the present year the Corporation, owing to the short supply of water available, determined to raise their scale of charges for the supply of water through garden hose. Mr. Cowl was formerly charged 10s. 6d. a year; but the charge was increased to £1, and the demand note for this sum was served in June. No objection was raised until November, when Mr. Cowl pointed out that he had a special contract as to the price at which the Corporation were bound to supply him with any water that he might require for the purposes of his garden. As a matter of fact, however, for three months out of the four, when it was ordinarily necessary to use the hose, the supply was curtailed; the water being turned off for the greater part of the day. He had no notice of the increased charge until June, when the year was half through; and he contended that the Corporation had they no power to make the increase, and that, under the circumstances, it was unreasonable to demand payment of the full amount. But he offered to compromise the matter on an equitable basis. Mr. Barber, on behalf of the Corporation, produced the contract, and said in pursuance of the terms therein mentioned, they had the power to vary the charge. Had Mr. Cowl communicated his objection soon after he received the demand note, as others did, the charge would in all probability have been reduced; but nothing was heard from him until the present month. After an ineffectual attempt to compromise the matter, the Bench made an order for the payment of 10s. 6d.—thus supporting the defendant's contention.

GAS SUPPLY IN SOUTH AFRICA.

COMMENCEMENT OF GAS-WORKS AT WOODSTOCK.

On Saturday, Oct. 20, the foundation-stone of the works which the South African Gas Company are erecting at Woodstock, for the supply of that town and the neighbouring villages on the road from Cape Town to Wynberg, was laid by the Mayor of Woodstock (Mr. W. Searle). The formation of the Company, with a capital of £100,000, was noticed in the JOURNAL about a year ago; and a joint concession from the Municipality of Woodstock and the Cape Town Divisional Council having been obtained, a site was secured at the former place as the centre of operations. The works have been designed by Mr. E. Herbert Stevenson, of Westminster; and, of course, will be furnished with the latest appliances for the economical manufacture of gas. They will cover an area of about two acres, and be capable of producing 100,000 cubic feet of gas per day. The retort-house will contain three settings of six retorts on the regenerative system; though two will be sufficient to meet the first requirements. All the necessary auxiliary apparatus will be provided, as well as offices and buildings for the accommodation of the Manager and his staff. The gasholder will be a two-lift one, contained in a wrought-iron tank. It will be 60 feet in diameter, and have a capacity of 88,000 cubic feet. Already 4000 out of the 5000 yards of mains (ranging from 12 down to 4 inches in diameter), which it is intended to lay, have been put down; so that as soon as the manufacturing plant is in order a supply of gas will be at the command of the inhabitants. The Municipality of Woodstock have arranged to light the streets. The works are in proximity to a railway line, with which they will eventually be connected by a siding; thereby facilitating the delivery of coal direct into the works from the docks. It is expected that everything will be ready for lighting Woodstock in about three months from the present time; and on their completion, arrangements will be made for giving a supply of gas to the villages of Rondebosch and Claremont. Mr. J. Maxwell is the contractor for the works; the Resident Engineer being Mr. Arnott. After the ceremony of laying the stone had been performed, the Mayor gave a brief address, in the course of which he remarked that the introduction of gas into the streets of Woodstock meant far more than the mere substitution of one mode of lighting for another. It was, to himself, conclusive evidence that the inhabitants were determined to take advantage of all the comforts of modern civilization, and thus render the suburbs of Cape Town more attractive, and, furthermore, to enhance the value of property. Not only would the interior of houses in the Municipality be rendered more comfortable by a superior method of illumination, but the streets would be lighted, and those crimes for which the hours of darkness were peculiarly suitable and generally chosen would naturally decrease. The ceremony of that afternoon, therefore, marked an important period in the history of Woodstock; and they might well pride themselves upon being the first of the suburban municipalities to take steps for the supply of gas and water. He need scarcely assure the Company that, as soon as they were in the position to supply gas, they would find the inhabitants ready and wishful to do their part in making the venture remunerative. The charge for gas would be 8s. per 1000 cubic feet, or somewhat less (by 2s. 6d.) than the rate charged in Cape Town. He was only giving expression to the sentiments of the public when he said that he wished the South African Gas Company every success in their enterprise. Subsequently the toast of "Success to the South African Gas Company" was proposed by Mr. Atmore, and responded to by Mr. W. E. Moore (one of the local Directors) as representing the Board.

THE HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY, LIMITED.

In view of the fact that this Company is the first to propose giving a supply of electricity to private houses of any size on terms at all analogous to those under which gas is furnished, it may be interesting to reproduce in our columns some extracts from a circular now being sent out to residents in Brompton, Earl's Court, South Kensington, and the immediate neighbourhood. It is intimated that, consequent on the approaching completion (on the 15th prox.) of their West Brompton Central Electric Lighting Station—adjoining the West Brompton Station of the Metropolitan District Railway—the Company are prepared to contract with residents in the neighbourhood for a supply of electricity to their houses on the following terms:—

Supply of the Light.—The householder can have any number of lamps installed on his premises; but in pursuance of the regulations of the Board of Trade, he is obliged, in demanding the light, to state the maximum supply he requires—i.e., he must declare the greatest number of lamps he may want to use at any one time. The householder need only avail himself of the maximum supply (which he can compel the Company to have always available for his use) to such extent as he requires. In the event of the householder wishing temporarily to increase the number of lamps available for use beyond that stipulated for in his maximum supply, he can do so by arrangement on giving 48 hours' previous notice in writing to the Company. The maximum supply demanded by the householder will be conveyed to his premises from the central station either by means of underground or overhead mains as the local authority may determine. After passing the main switch in the house, a simple but *absolutely reliable* meter will register the quantity of electricity actually consumed in the lamps. When any lamps are turned on or off, a greater or lesser amount of electricity is being consumed, and a greater or lesser amount is consequently passing through the meter; so that the quantity registered is exactly in proportion to the number of lamps in use from time to time.

Cost of the Light.—The quantity of electricity actually consumed on the premises will be ascertained quarterly, and the following charge made on the basis of a sliding scale, varying with the maximum supply demanded by the householder, as follows:—

1. At the rate of 1s. per Board of Trade unit* for the first 100 hours' consumption of the maximum supply demanded.
 2. At the rate of 8d. per Board of Trade unit for the second 100 hours' consumption of the maximum supply demanded.
 3. At the rate of 4d. per Board of Trade unit for any further quantity consumed.
- Rent of meter, instruments, &c., 5s. per Board of Trade unit of maximum supply demanded per quarter.

For example, suppose that 40 lamps are installed on premises in respect of which a maximum supply of one Board of Trade unit (which will permit of about 20 incandescent lamps of 16-candle power, or their equivalent, being alight at any one time) has been demanded, and that during the heavy winter quarter 20 lamps have been in use on an average for five hours each evening, the total consumption of electricity registered by the meter would be: 20 lamps × 5 hours × 92 days × 50 watts per hour = 460,000 watt-hours, or 460 Board of Trade units (50 watts per hour being the quantity consumed by a 16-candle power incandescent lamp of the best

* A Board of Trade unit (1000 watt-hours) may be estimated to supply about 20 incandescent lamps of 16-candle power (or an equivalent number of lamps of smaller candle power) for one hour.

efficiency). Then, the maximum supply having been fixed at one Board of Trade unit of 1000 watt-hours—i.e., the electricity required for 20 16-candle power lamps for one hour—and the actual consumption having been 460 Board of Trade units, the amount payable would be as follows:—

First 100 units at 1s.	£5 0 0
Second 100 units at 8d.	3 6 8
Balance of 260 units at 4d.	4 6 8
Lamp renewals, say 9 at 4s.	1 16 0
Rent of meter, instruments, &c.	0 5 0
	£14 14 4

Equal to an average charge of 6½d. per Board of Trade unit of electricity or less than 4s. per 1000 cubic feet of gas. In making comparison with gas, however, it must be remembered that greater economy can be exercised in the consumption of electricity by the facility with which the light can be turned on and off, and the consequent avoidance of the necessity of keeping the lamps alight when not required. In the event of such an extension of the Company's business as would permit of a reduction of charge, all consumers, whether new or old, will enjoy the benefit of the reduced tariff; and it should be also noted that every improvement in the efficiency of incandescent lamps by reducing the quantity of electricity consumed will further diminish the cost of the light to the householder.

Lamps.—The cost of the renewal of lamps is to be borne by the householder, who may use those of any maker he may prefer. The Company will be prepared to supply lamps of the highest efficiency at the price of about 4s. each. The best lamps are extremely durable, and ordinarily last for 1000 hours; so that in the case of an installation of 40 lights, in which each light is, on an average, in use for 250 hours during the year, there will be an average renewal of about 10 lamps per annum.

Installing.—The cost of installing the electric light on the premises is to be borne by the householder, estimates for which the Company will be prepared to furnish free of charge. In the event of the premises being wired by others, the work is to be done to the approval, and subject to the test, of the Company's Engineer. As a set-off against this outlay, it must be remembered that a large expense, which would be otherwise incurred for painting, decorating, &c., will be avoided.

Fittings.—In cases where the householder may prefer not to do away with his gas-fittings, he can have the electric lamps attached to them. The beauty of the electric light, however, is greatly increased by the use of special electroliers and fittings, which appliances, by the best makers, can be supplied by the Company in great variety and on the most advantageous terms.

Summary of Cost of the Light for Various Sized Installations.

(Based upon the probable consumption for the heavy winter quarter.)

Twenty 16-candle power incandescent lamps, or the equivalent thereof, in a house where the maximum number required to be used at any one time is 10 lamps of 16-candle power, or the equivalent thereof = a maximum supply demand of 0·50 of a Board of Trade unit. 10 lamps × 92 days × 5 hours × 50 watts = 230,000 watts, or 230 units.

First 100 hours of maximum supply demand of 0·50 of 1 unit = 50 units at 1s.	£2 10 0
Second 100 hours of maximum supply demand of 0·50 of 1 unit = 50 units at 8d.	1 13 4
Balance of 130 units at 4d.	2 3 4
Renewal of lamps, 5 at 4s.	1 0 0
Rent of meter, instruments, &c.	0 5 0
	£7 11 8

Gas at 2s. 9d. per 1000 cubic feet £5 6 3

Forty 16-candle power incandescent lamps, or the equivalent thereof, in a house where the maximum number required to be used at any one time is 20 lamps of 16-candle power, or the equivalent thereof = a maximum supply demand of 1 Board of Trade unit. 20 lamps × 92 days × 5 hours × 50 watts = 460,000 watts, or 460 units.

First 100 hours of maximum supply demand of 1 unit = 100 units at 1s.	£5 0 0
Second 100 hours of maximum supply demand of 1 unit = 100 units at 8d.	3 6 8
Balance of 260 units at 4d.	4 6 8
Renewal of lamps, 9 at 4s.	1 16 0
Rent of meter, instruments, &c.	0 5 0
	£14 14 4

Gas at 2s. 9d. per 1000 cubic feet £10 7 5

Fifty 16-candle power incandescent lamps, or the equivalent thereof, in a house where the maximum number required to be used at any one time is 25 lamps of 16-candle power, or the equivalent thereof = a maximum supply demand of 1·25 of a Board of Trade unit. 25 lamps × 92 days × 5 hours × 50 watts = 575,000 watts, or 575 units.

First 100 hours of maximum supply demand of 1·25 of 1 unit = 125 units at 1s.	£6 5 0
Second 100 hours of maximum supply demand of 1·25 of 1 unit = 125 units at 8d.	4 3 4
Balance of 325 units at 4d.	5 8 4
Renewal of lamps, 12 at 4s.	2 8 0
Rent of meter, instruments, &c.	0 10 0
	£18 14 8

Gas at 2s. 9d. per 1000 cubic feet £13 3 0

One hundred 16-candle power incandescent lamps, or the equivalent thereof, in a house where the maximum number required to be used at any one time is 50 lamps of 16-candle power, or the equivalent thereof = a maximum supply demand of 2·50 of a Board of Trade unit. 50 lamps × 92 days × 5 hours × 50 watts = 1,150,000 watts, or 1150 units.

First 100 hours of maximum supply demand of 2·50 of 1 unit = 250 units at 1s.	£12 10 0
Second 100 hours of maximum supply demand of 2·50 of 1 unit = 250 units at 8d.	8 6 8
Balance of 650 units at 4d.	10 16 8
Renewal of lamps, 24 at 4s.	4 16 0
Rent of meter, instruments, &c.	0 15 0
	£37 4 4

Gas at 2s. 9d. per 1000 cubic feet £26 1 0

THE PRICE OF GAS AT ROCHDALE.—The newly-appointed Gas Committee of the Rochdale Corporation held its first meeting last Wednesday. Alderman Petrie was re-elected Chairman. The principal topic discussed was the suggested reduction in the price of gas. It was at first proposed that the reduction should be 2d. per 1000 feet; but ultimately it was unanimously decided to recommend the Council to reduce the price of gas supplied to consumers within the borough by 3d. per 1000 feet. If this recommendation is approved by the Council the prices will be, for prompt payment—Under 10,000 cubic feet, 2s. 9d. per 1000 feet net; 10,000 feet and under 50,000, 2s. 8d.; 50,000 feet and under 100,000 2s. 7d.; and above 100,000 feet, 2s. 6d.

THE PROPOSED TRANSFER OF THE PARTICK GAS-WORKS TO THE GLASGOW CORPORATION.

OBJECTIONS TO THE SCHEME.

When referring, in the last number of the JOURNAL (p. 901), to the position of the proprietors of the above-named Company in view of the proposed acquisition of the undertaking by the Glasgow Corporation, it was stated that at the meeting held on the 8th inst. no intimation was given by the preference shareholders of any intention on their part to oppose the propositions of the Directors. We find, however, that these gentlemen are still dissatisfied with the agreement entered into by the Directors for the sale of the works; and they have addressed to their fellow-shareholders a circular setting forth their views on the subject. They consider, in the first place, that the price offered for the undertaking is, considering its prospects, ridiculously small; and they charge the Directors with having surrendered to the Corporation without discretion. They review the position of the Company, as shown by the last balance-sheet. According to the revenue account, there was a gross profit of £13,245. After providing for interest on debentures, interest on the reserve fund, general interest, and the dividend on the preference shares for one year, there was left a balance of £9047. A portion of this was employed in meeting several extraordinary items, amounting together to £5242. Out of the balance (£3805), the Directors wrote off certain amounts for depreciation, and for interest on the depreciation fund. This the preference shareholders regard as an injudicious act, in view of the possible annexation, inasmuch as the writing off of these sums had the effect of lowering the net profits, and consequently the selling price of the concern; and, moreover, they question the necessity for taking this course, seeing that the works have been kept in efficient repair, year by year, out of revenue. It is contended that, after reducing the price of gas to meet the reduction made by the Corporation, the profits of the Company in ordinary years are sufficient to pay a 6 or 7 per cent. dividend; and they say that no body of business men would come to an agreement by which a concern capable of paying 7 per cent. is bound down to pay only 4 per cent., and the shareholders' capital locked up for two years with this inadequate rate of interest. The lump sum of £122,370 proposed to be paid for the works, they maintain is not based upon any fair valuation of the property as a going concern capable of earning good dividends. The figure should, they think, be nearer £200,000 than £120,000. The circular concludes as follows:—"If we assume that the profits admit of a dividend of 7 per cent. being paid—and that is well within the mark—then 25 years' purchase of it (£7000) and the preference dividend (£1650) = £8650 amounts to £216,250. The price agreed on is not even based upon the low rate of interest accepted by the Directors pending the handing over of the concern to the Corporation; for if we add the preference interest or dividends, £1650, to the ordinary dividends at 4 per cent., £4000, and multiply the total, £5650, at 25 years' purchase, we get £141,250 as the value of the property, or over £18,000 more than the price agreed upon. The want of firmness in standing out for an equitable price, has greatly prejudiced the value of the property." These being the views of the representatives of the preference shareholders, it is probable that the proceedings at the adjourned meeting will be anything but tranquil. The opinion of the objectors to the scheme is that better terms may be secured by the Company defending their interests in Parliament when the Corporation apply for power to extend their boundaries.

IMPROVED GAS LIGHTING IN NEWINGTON PARISH.—At the last meeting of the Newington Vestry, the Works and Sanitary Committee recommended that new lanterns with single 10 feet burners should be fixed to the 148 columns in the eight main roads of the parish, at a first outlay of £173 18s. and afterwards at an annual charge of £303 4s. 4d. The recommendation of the Committee was adopted.

THE NEW WATER SUPPLY FOR WAKEFIELD.—A sample of the water now being supplied to Wakefield, and which is obtained from the Rishworth Moors, on the Peuline Range or backbone of England, was recently forwarded to Dr. C. Meymott Tidy, for examination; and he has just made a report to the Corporation as to the result of his analysis. He states that it is "most excellent water for a town's supply."

THE ALDERSHOT LOCAL BOARD AND THE GAS AND WATER COMPANY.—About the middle of last month, the Aldershot Gas and Water Company intimated to the Local Board their intention to apply to the Board of Trade for power to increase their capital by £20,000, to purchase 20 acres of land, and to supply gas and water beyond the district of the Local Board. The matter was referred to a Committee, who obtained a legal opinion from Messrs. Wilkins, Blyth, and Dutton, who pointed out that as the money proposed to be raised was for gas capital, the water and gas capital of the Company should be separated. There was a proposal to adopt the sliding scale for gas, which they advised the Board to oppose unless the Company would fix an initial price of 3s. per 1000 cubic feet. The clause in the proposed Order exempting the Company from penalties was also objectionable, as it practically prevented penalties being enforced by suggesting a regulation answer. A special meeting of the Board has been held since the receipt of the letter to consider the matter; and a communication was then read stating that the Company had decided to withdraw their application, on the ground that there was no time for further discussion before the advertisements should be issued to the papers. After an animated discussion, it was decided—notwithstanding the decision of the Directors—to meet them, if possible, on an early date to see what arrangement could be come to.

THE GAS QUESTION IN HAWES.—The township of Hawes-in-Bedale is, says the *Yorkshire Post*, at present the centre of a lively discussion on the respective merits of coal gas v. water gas for illuminating purposes. The leading men of the district have been agitating the community to bestir itself to introduce an illuminant to supersede the old-fashioned and dangerous paraffin lamps; and, after some correspondence on the matter, it was determined to invite representatives of the coal-gas interest and the British Water Gas Syndicate to meet the inhabitants and discuss the different methods. The coal gas representatives did not "turn up." But Messrs. Wildy and Brewer, from the British Water Syndicate, did; and a goodly number of representative Hawes men listened with deep attention to a most interesting and instructive lecture on water gas by Mr. Wildy, who illustrated the method of manufacture of gas from water by diagrams on a blackboard. Mr. Wildy, in suitable language (avoiding as much as possible all technical terms), made himself thoroughly understood to his audience. The pertinent questions put to the lecturer by some of those present showed that the subject was one which had already been carefully considered; whilst the suggestion of a well-known gentleman in the room, to raise a subscription there and then to send delegates to Leeds to see the water-gas plant at the Leeds Forge, showed the practical Yorkshire mind. The result of the suggestion was that a sum of money was raised, and three gentlemen were selected to represent the meeting, and visit Leeds to view the water gas making, and witness experiments as to its illuminating and heating properties.

STOCKTON AND MIDDLESBROUGH WATER BOARD.

THE WORKING DURING THE PAST HALF YEAR.

The accounts of the Stockton and Middlesbrough Water Board for the half year ending Aug. 13 last have just been issued. They show that there has been a capital expenditure in the half year of £17,994; bringing the total cost of the undertaking up to £1,238,738. Of the capital expenditure, the principal items are as follows:—On account of the Hury reservoir, £10,288; reservoir at Sadberge, £2437; conduit No. 5 (Sadberge to Stockton), £125; pumping plant at Broken Scar, £1368; reservoir at Fighting Cocks, £683. The sums received on capital account during the half year amounted to £30,000; bringing the total amount up to £1,243,094—being £4355 in excess of the amount expended. The revenue account shows the income to have been £28,347; being an increase of £837, as compared with the preceding half year, and of £1054 13s. as compared with the half year ending Aug. 13, 1887. There was an expenditure on revenue account during the half year of £6703 12s; being an increase of £24, compared with the previous half year, and of £277 16s. as compared with the half year ending Aug. 13, 1887—this increase being more than accounted for under the head of rates and taxes. The balance carried to the net revenue account is £21,643, as compared with £20,829 19s. in the former half year, and £20,836 in the six months ending Aug. 13, 1887. The net revenue account is debited with £290, in respect of sundry charges for interest, and is credited with the rents of land in Baldersdale, and interest received from the bank. After being so dealt with, there remains a balance of £21,431, of which £18,000 has been paid to the Corporations and the Local Board; and there remains a balance of £3431, which it is proposed to carry forward, as it is understood that the effect of clause 12 of the Act of 1885 is to relieve the funds of the constituent authorities of any charge on revenue account for the past year. During the summer the works in connection with the Hury and Sadberge reservoirs have made excellent progress; the latter may be expected to be ready for use in the early part of next year, and the former probably in the early part of 1890. The Sadberge reservoir mains are in such an advanced state that they will be ready for use simultaneously on completion of the reservoir, when it is confidently expected that the numerous complaints of want of pressure in the mains will be remedied. The growing demand for water for manufacturing purposes, to which attention was called in the last two reports, it is stated has continued without interruption during the past half year. The prospect of a still greater demand in the immediate future, and the best means to meet it, have engaged the serious consideration of the Board; and, after much deliberation, it has been decided that it is not safe any longer to defer the commencement of the construction of the Blackton reservoir. The Engineer has therefore been instructed to prepare the plans and specifications requisite to enable the Board to enter into contracts for the works; the land upon which the reservoir is to be constructed having been acquired by the Board some years ago.

BRADFORD CORPORATION WATER SUPPLY.

THE PREVENTION OF WASTE.

The Engineer of the Bradford Corporation Water-Works (Mr. A. R. Binnie, M. Inst. C.E.) has just presented to the Water Committee a report on the working of the Deacon waste-water meter system, which has now been in use in the borough for about three years.

In commencing the report, Mr. Binnie states that the whole borough has been divided into 38 districts, governed by 29 6-inch and 9 4-inch meters. In beginning work in any district, a complete register is made of all the circumstances of each particular supply included in it. As soon as this information is obtained, outside stop-taps and Deacon's detection meters are fixed, and the district under observation is ready for inspection. In working it is assumed that, between the hours of twelve midnight and five a.m., all ordinary use of water is at a standstill, and that which is found passing through the pipes is running uselessly to waste. Of course, as is pointed out, this is not exactly the case in any town, and is far from being so in a large centre of manufacture like Bradford. As soon as the meters are set to work, several trials are made of the flow through them into the district between the hours of midnight and five a.m. The lowest flow per hour is noted on the diagram; and the result, multiplied by 24, is, for the purpose of the work, assumed to be waste—the object being, by the detection and repair of leaks, to reduce this night, or rather early morning flow to the smallest possible amount.

The modes in which, in the first instance, leakages are detected are two. First, as to the distribution-pipes in the street. The meter having been set to work between midnight and five a.m., each of the branch-pipes is in succession shut off. It is clear that if no water is passing through them, this will have no effect on the meter reading; but, should leakage be going on, the cessation of its flow is at once recorded on the meter diagram, which records the exact time of such cessation, and, as a record is also made by the inspector of the time when each street was shut off, a comparison of his note-book with the meter diagrams at once detects in which particular street the leakage was situated. The first preliminary trial, the report says, generally detects large flows from defects in the iron pipes, which between 1886 and 1888 have been as follows:—From pipes of 1½ inch diameter, the number of leaks has been 1; from 2-inch pipes, 4; from 2½-inch, 1; from 3-inch, 146; from 4-inch, 41; from 5-inch, 5; from 6-inch, 20; from 9-inch, 2; from 12-inch, 4; from 18-inch, 5; from 30-inch, 1. The total number of leaks was 230, exclusive of 35 similar cases detected by the same means previous to 1886. The second mode of detecting leakage refers to such as occurs in private houses. When it is believed that all the iron supply-pipes in the district are in good order, but that leakage is still detected going on in the district, that street in which it is suspected is shut off and isolated from the others. The meter diagram then records the flow in that particular street only. The inspector afterwards visits each outside stop-tap which governs the private supplies, listens with his stethoscope, and if he hears water running, closes it. As he always notes the time at which he does so, a comparison of his book with the meter diagram at once indicates in what particular house supply the leakage is situated. By this means many hidden and underground leaks are detected, which by mere visual inspection could never be discovered; and householders are saved the annoyance of useless visits from inspectors, as they are enabled to go at once to the exact house where the leak exists instead of visiting all the houses in a street to find perhaps one or two faulty taps, cisterns, or broken pipes. Between 1886 and 1888 the following causes of leakages were detected:—water-closets, 145 taps, 1498; lead water-pipes, 851; urinals, 15; fire-plugs, 91; valves, 30; ferrules, 43; water-taps left open, 80; and miscellaneous leakages, 220—making a total of 2973 leakages.

Speaking of the outcome of the work in the whole of the 38 districts combined, Mr. Binnie says that, when they introduced the system the assumed night leakage was at the rate of 4,080,600 gallons per 24 hours, which, after inspection and repair, has been reduced to 1,041,600 gallons per 24 hours; showing that a leakage of 3,039,000 gallons has apparently been prevented since commencing the work in 1885. As latterly the staff work with greater accuracy due to increased experience, and many

of the meter's diagrams are often taken on Saturday and Sunday nights so as to avoid trade meter supplies interfering with the result, and which was not done in all instances at the commencement of working, Mr. Binnie is inclined to think that the actual daily saving is less than the above figures really show, and which he estimates at about 2,000,000 gallons a day actually saved. But, he continues, even the whole of this saving of 2,000,000 gallons a day cannot any longer be reckoned on as available for use, as between 1885 and 1887 the trade supply by meter has increased nearly 500,000 gallons a day, and the supplies to property within the borough have increased in the four years 1885 to 1888 by 2809.

As to the expense incurred in the whole of the work since 1885, the following is a brief summary of the charges up to date:—Capital for meters and stop-taps, £5152; salaries and working expenses, £2631—or a total of £7783. At first sight it would appear, continues the report, that there have been saved about 2,000,000 gallons a day, or 2,190,000,000 gallons in three years. As the gross expenditure has been £7783, this would be at the rate of 0·85d. per 1000 gallons. But although such a rough mode of viewing the question is satisfactory in showing the generally economical nature of the work, yet the correct method is to take the capital and working expenses in proper proportions for one year only. The capital charges are supposed to be paid off in twelve years; therefore one-twelfth of £5152 equals an annual charge of £429 6s. 8d. Salaries, &c., for the past year amounted to £1102 8s. 4d. These two amounts added together make £1531 15s. (estimated in 1885 to cost £1540) as the total annual expenditure in saving 2,000,000 gallons a day, or 730,000,000 gallons per annum. This is at the rate of 0·503d. (say ½d.) per 1000 gallons; the value of the water saved, at the rate of 6d. per 1000 gallons, being, of course, £18,200.

PROPOSED PURCHASE OF THE TONBRIDGE WATER-WORKS BY THE LOCAL BOARD.

A Meeting of ratepayers was held at Tonbridge last Wednesday to consider the question of the Local Board acquiring on behalf of the town the property of the Water Company. Mr. W. Hodgeskin, who presided, in opening the proceedings, remarked that he was in the awkward position of being a shareholder and Director of the Company; but whatever the ratepayers decided upon, he would concur in. Mr. Rice addressed the meeting at length. He considered the report of the Local Board was in favour of the purchase of the works; and he was afraid that if they did not acquire them now, they would lose this valuable property. Two or three years ago he addressed a letter to the ratepayers on the question, when he submitted that the purchase of the works would be a distinct advantage to the town. The greater part of the loans would be paid off in 30 years; the works would be the property of the town; and the revenue would, to the extent of £1200, go to reduce the general district rate. He went on to refer to a circular which had been distributed by the opponents of the project, in which, among other things, it was stated that the Local Board would not pledge itself to borrowing the money for the purchase at 3½ per cent. for 30 years; but a private gentleman had given him (Mr. Rice) permission to say that he would find the money at that rate of interest. Then, it was asserted that the Company's profits were less than £1000 per annum; but, by their own showing this was incorrect. With regard to the statement that the mains had been in use 30 years, and in a few years would have to be renewed at a cost of £1000 per mile, if this were true, it was strange that the Company should want to retain their undertaking. He thought the town would make a mistake if they did not purchase the undertaking. A number of questions were then put by various ratepayers; and subsequently Mr. Rice moved a resolution urging the Local Board "without delay to carry out the terms of the Provisional Order, by the immediate purchase of the water-works undertaking." Mr. Millidge seconded the motion; and after some further discussion, it was carried with but two dissentients. It was then decided to forward the resolution to the Local Board, a Committee of which body have already reported in favour of the purchase.

LEAD POISONING AT PUDSEY.—At the meeting of the Pudsey Local Board last Wednesday week, the minutes of the Sanitary and Hospital Committee contained a report made by Messrs. Reynolds and Branson, of Leeds, of an analysis of the water supplied by the Calverley Water Company to the Pudsey district. The Chairman said they were told that not fewer than from 40 to 60 cases of lead poisoning had occurred in the town; and it was highly desirable that the ratepayers should be placed in possession of the facts which had led to the water supplied to the district being sent for analysis, as he was of opinion that the remedy was largely in the hands of the ratepayers themselves. The Clerk then read the report, which showed that the samples of water submitted contained as much as 13·20ths of a grain of lead per gallon, which the analysts regarded as a distinctly injurious quantity. The Chairman said it appeared that the cases of lead poisoning had occurred in families residing in houses a long distance from the mains, and that the poisoning had resulted from drinking water which had been all night in the lead pipes conveying the water from the mains to the houses in question. He was of opinion that the people themselves could obviate a great deal of the mischief if they allowed the water to run to waste every morning for some time, so as to empty the pipes before drawing water for domestic use. After some conversation, it was decided that a copy of the analysts' report should be sent to the Calverley Water Company, and that, after their answer had been received, further action could be taken in the matter.

THE WATER QUESTION AT BRIGHOUSE.—A Brighouse correspondent writes, under date of Nov. 16, that "the Directors of the Rastrick Water-Works Company, Limited, have given notice of their intention to apply to Parliament during the ensuing session for an Act incorporating their Company, and conferring upon them the customary statutory rights and privileges, and restrictions usually vested in and imposed upon undertakings of a like nature. The Company," it is remarked, "was established shortly after the very serious drought and scarcity of water that prevailed in the year 1868; and for the space of 20 years it has solely supplied the district with water. The present action of the Company in seeking incorporation and more extensive capital powers is the outcome of the growing requirements of the district, which causes a corresponding increase in the consumption of water, to cope with which the Company are intending to make considerable extensions in their works. At present they supply the bulk of the water in Rastrick for domestic and other purposes; the Local Board having no interest whatever in the water supply. Some half-dozen years ago a vigorous agitation sprung up in the district in favour of the Local Board purchasing the Water Company's plant; but the proposal was contested, and was ultimately allowed to lapse. The proposed action of the Directors came as a surprise yesterday to the bulk of the water consumers and ratepayers in the district; and opinions were freely expressed that the Bill should be opposed by the Local Board; and that the opportunity should also be taken to 'buy out' the Company before any further capital is sunk in the undertaking. The capital of the Company is £6000, in 2000 shares of £3 each, all of which are fully paid up. Last year the Company paid a dividend of 8 per cent."

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

The Dundee Gas Commission met for the first time after the election on Tuesday. Almost the only business transacted was the appointment of officers. Mr. Nicoll, Treasurer of the town, was re-elected Convener of the Finance Committee; and Mr. Lindsay, Convener of the Works Committee. In acknowledging his re-election, Mr. Nicoll said he hoped the finances of the Commission would prove as satisfactory this year as last; and he added that, so far as the year had gone, there was every reason to expect that the accounts would turn out favourably.

The storm which I mentioned last week, as having damaged several gas and water works, was the occasion of a peculiar effect at Portobello. The large gasholder got twisted by the gale; and while it was being adjusted, unpurified gas was allowed to enter the mains by the bye-pass valve. This is the explanation given by the Gas Company. What the inhabitants of the town felt was a sense of oppression, and a difficulty of breathing, in apartments where gas was burned. On Saturday night shopkeepers were obliged to keep the doors of their premises open; and on Sunday the odour in the churches was of so sulphurous a nature, that the congregations could scarcely remain in the buildings. It was reported locally that the occurrence was owing to the mistake of a workman, committed while the Manager was giving his attention to the gasholder.

Mr. Adam Pratt, whom I have before referred to as the head and front of the agitation in Aberdeen upon the alleged overcharges for gas, having been returned to the Town Council, this body have done the wisest thing possible in unanimously appointing him to the Gas Committee. Now that Mr. Pratt is on the Gas Committee, he may get his eyes opened to the extent of being obliged to look at things in a different light than when he was an agitator. Can this be the explanation of his attitude at a meeting of the Gas Committee on Thursday? At that meeting, Mr. Clark drew attention to the long delay in receiving the report as to the gas consumers' grievances, and asked when it was going to be finally brought forward. Mr. Cook made a remark that he thought Mr. Pratt would have pushed this matter; but Mr. Pratt, in reply, said there was time enough when the report was before them. The Convener said the report would be before them very soon; and it was stated that the Sub-Committee appointed to furnish a statement would meet in a day or so.

After a good deal of difficult negotiation, the burgh of Linlithgow seems to be in a fair way to obtaining an additional water supply. The Local Authority are being pushed on to take this step, as well as to improve the sanitary condition of the town, by the Board of Supervision. A complaint by the Board against the Local Authority has been for several months before the First Division of the Court of Session; and procedure in it has been more than once delayed at the request of the burgh, to allow the negotiations for means to remove the evils complained of to be made. A report—the sixth on the subject—was made by the Local Authority to the Court on Thursday. In it they stated that they had resolved to impound the water on the estates of Hiltly and Preston; but that they had been threatened with legal proceedings by paper makers who use the water collected on the Preston estate; and that in view of this opposition, as well as the opposition of a minority of themselves who favoured a proposal to take the water from the Piccarton Burn, they had resolved to apply to Parliament for a Provisional Order authorizing them to have the Hiltly-Preston works executed. In addition, they are endeavouring to acquire, by agreement, the water rights of the two estates. The Court were asked to allow further delay; and this was readily granted. Mr. J. A. Warren, C.E., of Glasgow, has reported, with reference to the Hiltly-Preston water, that "it is free from sewage, and is an upland water of great purity, well suited for drinking purposes." The total addition to the water supply would be 27,967 gallons per day, or seven gallons per head per day. He proposes to construct a reservoir to contain 12 million gallons, and estimates the cost of the scheme at £3960.

The Edinburgh and District Water Trustees have issued notices that they propose to apply to Parliament for a Bill to increase their borrowing powers, to enable them to take steps to reduce excessive use of water, to terminate existing agreements for the supply of water to other Water Trustees in the district, and to enter into new agreements with these Trustees. It is proposed to increase the borrowing powers, which are nearly exhausted, by £50,000.

The water supply of Aberdeen does not appear to have benefited to anything like the extent expected by the opening of the two new reservoirs. The Water Committee on Thursday had before them complaints by residents in the higher parts of the city, that there was not sufficient pressure; and it was stated that the new reservoir at Mansfield had not given any increased pressure to parts of the town whence the complaints emanated. The Committee ordered reports to be prepared on the subject of the pressure in all the districts from which there were complaints, in order that they may be able to equalize it.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

There seems to be every probability that the next move of any importance in connection with gas affairs in the neighbouring town of Paisley will be the abolition of the meter-rent. This matter came prominently forward in the late municipal elections. An opinion was expressed at a meeting [of the First Ward electors that, as they had now such cheap gas in the town, the Gas Trust should turn their attention to a reduction of the charges for meter-hire; and Mr. Smith, a member of the Council, in replying, stated that he had canvassed the members of the Town Council with considerable success to have the meter-hire abolished. He promised that if he was sent back to the Council, he would press the matter to an open division. At the same meeting an elector, after assuming that the meter-hire would be abolished, asked what consideration the members of the Gas Trust would give to those consumers who had purchased their own meters. Ex-Bailie Macfarlane remarked that the subject broached by the elector would doubtless receive attention; and those persons who had purchased their meters would likely be recompensed. On this point, the Chairman of the meeting suggested that a portion of the annual gas surplus might be used in the event of the meter-hire being abolished to recompense those who had purchased meters; and Ex-Bailie Macfarlane stated that he was quite willing that this should be done.

Complaints are being made in various towns as to the inadequacy of the street lighting. At the meeting just referred to, one of the speakers stated that there was an insufficiency of lamps in certain streets in the burgh; and that, in fact, the streets throughout the whole of the West-end were not half lighted. Then, as regards the street lighting in Greenock, a correspondent in one of the local newspapers calls attention to the condition of several parts of the town; one portion named, he says, being at nights and in the early morning in a state of utter darkness. Referring to the complaint made by the correspondent, the Editor of the paper says that there is a great amount of truth in the accusation, and

asserts that at the present time, even when all the shops are lighted up, the main thoroughfare of the town has a very gloomy appearance.

The subject of insufficient street lighting was also before the Town Council of Stirling, at the monthly meeting last Monday. A long minute in reference to the public lamps was submitted by the Lighting Committee, in the course of which it was stated that the Convener had asked the Gas Manager (Mr. P. Watson) to take out of the lamps all the No. 4 burners except four. The Committee had compared the light given by such a burner in one lamp with that afforded by a No. 3; and they were of opinion that the difference of the light was not worth the additional cost of 10s. per lamp. They recommended that only No. 3 burners should be used in the lamps. In the course of the discussion, several complaints of insufficient lighting were made by members of the Council; and a motion was subsequently made by Mr. McQueen, and agreed to, to the effect that the Lighting Committee should be empowered to improve the lighting in certain districts.

On Thursday of this week business was done on the Glasgow Stock Exchange in the shares of the Partick, Hillhead, and Maryhill Gas Company, when 81s. per share was paid, which showed no change. Sellers were wanting 82s. Yesterday business was again done at that price.

Sulphate of ammonia is steadily advancing in value; the spot price this week having reached £12 15s. per ton, and close on £13 per ton has been named as the forward price.

A very material advance has been obtained by the Johnstone Gas Commissioners in this year's contract price for the residual products—£220, as against £149 last year. Some years ago more than £500 was obtained at Johnstone for the residuals.

After a little irregularity in the early part of the week, the Glasgow pig iron warrant market has for the last day or two presented more firmness; the week closing with a very hopeful tone. Over the week Scotch warrant iron has fallen in price about 3d. per ton; Cleveland, 6d.; and hematite iron, 2d.

The local coal trade continues to be exceedingly active in almost every department, with firm prices. All fears of a strike among the miners have disappeared, as the advance of wages conceded by the coalmasters has generally been accepted.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Nov. 24.

Sulphate of Ammonia.—There has been some further improvement in sulphate; but unfortunately the nitrate market exhibits symptoms which do not augur well for the immediate future. The gravamen of the moderating attitude of nitrate values is evidently found in the figures cabled in reference to the November shipments. These are apparently thought heavy (105,000 tons), especially as the loadings for December are stated to be close upon this figure (102,000 tons). Adding thereto the probability of large shipments by steamers, the doubts as regards any deficiency during the early spring months seem to have been palpably removed. As it may be interesting to compare the shipments and loadings of previous years, they are given below. After saying this much about nitrate, which has been made responsible for the recent advance in sulphate, it remains but to be remarked that, whatever decline may take place in nitrate rates, it does not necessarily follow that sulphate will adopt the course of nitrate in this direction. It has been stated before that sulphate did not advance quite as much as nitrate; and it cannot be gainsaid that the position of the former is exceptionally strong—admitted, though it be, that very large quantities are held in second hands for speculative account. It must be assumed that the demand is far from satisfied; but the upward tendency will receive a check because the impetuous operations of consumers, excited by the nitrate movement, will now cease, and they may hold off until the time of actual requirements. The production (now getting very heavy) does not so far clog the market, which closes very steady at £12 12s. 6d. to £12 15s., at the various ports. Nitrate on spot is quoted at 11s. 3d. per cwt., and is somewhat dull.

Nitrate Shipments to Europe during November 1884-1888.

1888.	1887.	1886.	1885.	1884.
Tons 105,000	102,000	69,000	46,000	52,000

Loading on the 1st of December.

LONDON, Nov. 24.

Tar Products.—There is a little better demand for creosote for burning purposes; and both crude and crystal carbolic acid are more inquired after. Benzoles are undoubtedly weaker; whilst pitch is nominally quoted higher, though buyers will not pay the prices now named. Prices may be taken as follows:—Tar, according to position, 17s. 6d. to 22s. 6d. per ton. Benzol, 90 per cent., 8s. 1d. per gallon; 50 per cent., 2s. 5d. Toluol, 1s. 7d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 1d. per gallon. Light oil, 8d. per gallon. Creosote, 2d. per gallon. Pitch, 17s. to 20s. per ton. Carbolic acid (crude), 3s. 9d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 5d. per unit; "B," 1s. 3d.

Ammonia Products.—Sulphate is in excellent demand; and the price continues to advance. Sales have been reported as high as £12 17s. 6d.; but the average price of the week will not exceed £12 10s. to £12 12s. 6d. per ton. Prices of other products are: Gas liquor (5° Twaddle), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £25. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Nov. 24.]

Tar Products.—The rise in value of tar products has not been without effect upon the price of tar. The last price we have heard of as being realized for tar of good quality is 29s. per ton at the gas-works, upon which there was a carriage of 1s. 10d. Benzoles continue firm; and last week's prices may be said to be ruling to-day. The demand for creosote and solvent naphtha is very good; and the effect of the Wells' light upon this market has made itself felt in the Manchester district. Crude carbolic acid is reported firmer; and at the same time crystals have a higher tendency, though some attribute this only to speculative agencies. Anthracene is very firm; and the report that a split had occurred in the foreign alizarine market is making producers here hold all the more firmly. To one maker, 1s. 6d. has been offered for "A" quality, and has been refused, as both he and others expect finally to get much more. Pitch has been rising lately; and we hear Beckton is asking 20s. per ton. To our own knowledge, business has been done in Yorkshire at 17s. 6d., and in other districts at 18s. f.o.b. As a specimen of inland business, the requirements

of the Manchester Corporation for the next twelve months have just been secured at 10s. per ton.

Sulphate of Ammonia.—The market in ammonia salts has been very firm indeed during the past week; and both sulphate and muriate have risen in price. Hull sulphate stands to-day at £12 16s. 3d. f.o.b.; the price at Leith being £12 15s. London outside makes are fetching £12 12s. 6d.; and though Beckton price is nominally £12 10s., they are not sellers for the moment.

A LAMPLIGHTERS' BENEFIT SOCIETY.—The lamplighters employed by the Manchester Corporation have formed a sick and superannuation society; and at its first annual meeting last Saturday week, it was reported that there are 101 members, with funds amounting to £378 8s. A burial fund has been added to the sick or superannuation branches. The subscription per member is only 6d. weekly, and an additional amount is received from fines.

SALE OF SHARES.—On Wednesday last, 100 new "B" shares in the *Horsham Gas Company*, of the nominal value of £10 per share, the maximum dividend on which is 7 per cent., were sold by auction at Horsham, in lots of from one to five. The following are the prices realized: Three shares sold at £14 2s. 6d. each; twelve, at £14 5s.; fifty, at £14 7s. 6d.; fifteen, at £14 10s.; fifteen, at £14 12s. 6d.; and five, at £14 15s.—the total amount produced being £1442 15s., or an average of £14 8s. 6d. per share.

THE NORTHERN COAL TRADE.—In the Northern coal trade, there is a good demand for steam coal; but it is less than it was, as is usual at this period of the year, and a further contraction of the demand must be looked for now the winter will close the ports. The current price for best steam qualities must be put at about 8s. 6d. It is believed that the wages agitation will be settled by the miners accepting the advance offered. In the gas-coal trade, there is difficulty in meeting contracts, owing to the miners restricting the output. One of the chief Tyneside gas-coal collieries used to obtain 2200 tons of coal daily; but it now rarely exceeds 1900 tons, and it is evident that the margin, after meeting contracts, must be a limited one. For that small margin, from 7s. 6d. to 8s. 6d. per ton is asked and obtained. There is, however, a probability that next month the miners will work better, as they usually do before the holidays. Household and manufacturing coals retain their old features; but coke sells more freely, and gas coke would realize 8s. 6d. to 9s. per ton for shipment, were it readily obtainable. The coal trade promises better even for next year—increasing cost of timber and increasing wages tending to make prices higher.

† Next dividend will be at this rate.

PORTSMOUTH WATER COMPANY.—At the half-yearly meeting of this Company on Thursday last, the Directors reported that the expenditure on capital account during the six months ending Sept. 30 was £10,286. Part of this outlay was on account of the new pumping station at Bedhampton Springs, with which good progress has been made. During the half year 3306 yards of additional street mains of various sizes were laid; and 663 yards of new mains in place of old. There were 694 additional house services laid on, including 25 meter supplies. The total number of premises now supplied by the Company is 31,759. The average daily supply of water for all purposes in the half year was 5,457,000 gallons; being a decrease of 31,000 gallons per day, as compared with the same period of last year. The revenue from all sources amounted in the six months to £23,313; and the expenditure, to £7817—giving a balance of £15,496. The sum available for dividend was £16,651 7s. 2d., subject to the usual deductions. The report was adopted; and dividends at the rate of 10 per cent. and 7 per cent. on the different classes of shares were declared. It was also agreed to carry £500 to the renewals account; leaving a balance of £2387 to be carried forward.

THE LONDON COAL DUES.—In the House of Commons last Thursday, Sir J. Pease asked the Attorney-General whether, on the expiration of the London Coal Dues in July, 1889, it would be within the power of the Corporation or other City authority to exercise an alleged obsolete right of measuring or weighing all coals coming within the Port of London under certain charters of James I. and James II., or other alleged title, and to levy therefor a due of 8d. or some other sum per ton; and, if so, whether Her Majesty's Government proposed to take steps to repeal such power. The Attorney-General, in reply, said he could not express an opinion upon an abstract and very difficult question of law, and one which depended upon the exact nature of any claim which might be made by the Corporation. With regard to the latter part of the question, he said he was authorized to state that in the event of any such claim being made, the Government would carefully consider the whole subject. Mr. Brunner pointed out that the matter was of great importance; and he asked whether the Attorney-General would undertake to inquire into the subject, and advise the Government to bring in a Bill before the claim was made. Sir R. Webster replied that it was impossible to give any such undertaking.

GWYNNE & CO., ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C. GWYNNE & BEALE'S PATENT GAS EXHAUSTERS & ENGINES.

Telegrams: "GWYNNEGRAM, LONDON." Telephone No. 2698.

Exhausters of nearly all sizes in Stock.

Prize Medals at all the Great International Exhibitions.

Exhausters equal to a total capacity of more than 26,000,000

cubic feet passed per hour have been supplied by us.

Our new Patent Non-Fluctuating Exhausters, to work without the slightest oscillation or variation in pressure, are strongly recommended.

MAKERS OF EVERY DESCRIPTION OF HYDRAULIC AND GAS MACHINERY.

Gwynne & Co.'s New Catalogue and List of Testimonials can now be obtained on application.

Exhausters and Vertical Engine as supplied for both the Fulham and Bromley-by-Bow Stations of The Gaslight and Coke Company.

We supply only the very highest quality of Machinery; and our Exhausters are constructed of large size to run at slow speeds.

OXIDE OF IRON.

O'NEILL'S Oxide has a larger annual sale in the United Kingdom than all other Oxides combined. Purity and uniformity of quality guaranteed. Pamphlet, "How to Purchase Bog Ore," to be obtained on application.

Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C.
JOHN Wm. O'NEILL, Managing Director.

ANDREW STEPHENSON, Agent for the GAS PURIFICATION AND CHEMICAL COMPANY, Limited, Palmerston Buildings, Old Broad Street, London, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 30, St. Andrew Square, EDINBURGH. } Scotland.
No. 54, BERNARD STREET, LEITH.

SULPHURIC ACID, B.O.V., for Sulphate of Ammonia Making. Guaranteed clear, of full strength, and to produce a fine white-coloured salt. Delivered in carboys or railway tank waggons.

For prices and terms address BALE, BAKER, AND CO., 120 & 121, Newgate Street, LONDON.

ADVERTISER seeks Engagement with a Gas Company. Considerable experience in all kinds of Stoves, Meters, and general Fittings, Accounts, Shorthand, and knowledge of Gas Testing. Age 28. First-class references. Address No. 1661, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

GAS Manager wants a Situation. Has been Six years in present appointment, and holds excellent testimonials. Thoroughly experienced, and not afraid of work. Age 33 years, and married. Apply by letter to No. 1660, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

WANTED, a Man accustomed to the Gas-Stove trade. Must be able to Fit and Sell. Address "GAS," care of Advertising Offices, 103, QUEEN VICTORIA STREET, E.C.

WANTED, a Second-hand Livesey WASHER, sufficiently large for 45,000 cubic feet per hour. Must be in good order. Price and full particulars to W. L., 55, Pyenest Street, Sbelton, STOKE-ON-TRENT.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE AND CO., 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56,

MILLBANK STREET, LONDON, S.W.
[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c.
** See Advertisement on Page III. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield,

AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings.
** See Advertisement p. 958 of this week's issue.
Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas- Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham.
Analysis of Coal, Oxide, and all Gas Materials.

WANTED, a Gas-Fitter, also a Main and SERVICE LAYER.
Apply to the MANAGER of the Gas-Works, HINDLEY.

WANTED, Tenders for Ammoniacal

LIQUOR 7° to 9° Twaddel. Must be removed in consignments of about 900 gallons every three to four weeks.

Reply to F. G. DEXTER, Manager, Gas-Works, WANTAGE.

FOR SALE—Suitable for a Gentleman's

Mansion, &c.—A COMPLETE 3-INCH GAS-WORKS PLANT, consisting of three Mouthpieces for Settings of Beds of two and one, with 5-inch Ascension Pipes, Cast-Iron Hydraulic Main, 12 inches diameter; Vertical Condenser, 10 feet high; two Purifiers, 4 feet 6 inches by 2 feet 6 inches by 2 feet deep, with Covers and Centre-Valve; Gas-holder, 25 feet 6 inches diameter 10 feet deep, with Tripod Framing, Chains, and Weights, Inlet and Outlet Pipes and Valves.
All in first-class order; erected 1880.

Further particulars and order to view to be obtained from the undersigned, to whom tenders are to be addressed on or before Dec. 8.

T. H. MARTIN, Assoc. M. Inst. C.E.
Gas-Works, New Barnet, Nov. 16, 1881.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized, White Enamelled, and Hydraulic Tubes and Coils JOHN SPENCER, Glohe Tube Works, WEDNESBURY and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.

Highest References and all particulars supplied on application.

HUTCHINSON BROTHERS, Barnsley,

Gas Engineers and Contractors, Makers of Gas-Meters and General Gas Apparatus, Sulphate of Ammonia Plant, Tools, and Sundries.

** See large Advertisement in last week's issue, page 911.

FOR SALE—A Station Meter in Round

Case, to pass 12,000 cubic feet per hour, with Clock Tell-tale, Water-Level Indicator, &c. The Meter is being removed to make room for a larger one. Inspection invited.

For particulars, apply to Mr. JOSEPH HEYDON, Gas-Works, MANSFIELD.

FOR SALE—A valuable French and

GERMAN PATENT for Gas Apparatus. Is Selling rapidly in England. Good testimonials.

For particulars, apply to No. 1658, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

(By Order of the ROYAL COLLEGE OF SURGEONS.)

CRYSTAL PALACE DISTRICT.

SALE OF GAS SHARES.

THURGOOD and MARTIN have received

instructions to Sell by Auction, at the Auction Mart, Tokenhouse Yard, E.C., on Thursday, the 6th of December, 1888, at Two o'clock precisely, in 219 lots cum dividend, £24,780 in the STOCK OF THE CRYSTAL PALACE DISTRICT GAS COMPANY, producing Dividends at the rate of 10 per cent., 7 per cent., and 6 per cent. respectively; also 375 £6 FULLY PAID 7 PER CENT. SHARES in the Capital of the same Company, which is a specially safe and easy investment for large or small sums, the dividends being secured against fluctuation by ample Reserve and Insurance Funds, and the increasingly profitable district of the Company.

Particulars and Conditions of Sale may be had of Messrs. WILDE, BERGER, and MOORE, 21, COLLEGE HILL, E.C., Solicitors; at the PLACE of SALE; and of the AUCTIONEERS, 27, CHANCERY LANE, W.C.

Shares may be paid up in full, and 5 per cent. Interest will be allowed upon Calls paid in advance.

THE SOUTH AFRICAN LIGHTING ASSOCIATION LIMITED.

Incorporated under the Companies' Acts, 1862 to 1886.

CAPITAL - - - - - £50,000,
IN 5000 SHARES OF £10 EACH.

PRESENT ISSUE, 5000 Shares of £10 each.—Payments, £1 on Application; £2 on Allotment; £2 a fortnight later; and the remainder in Calls of not more than £2, at intervals of not less than three months.

The intention being to call up the whole amount within 18 months.

ABRIDGED PROSPECTUS.

The objects of this Association are the providing of artificial light to towns in South Africa, the acquisition of existing and the erection of new works, and the supply of apparatus for lighting by Gas, Electricity, or Oil.

Acting on the advice of Mr. Corbet Woodall, M. Inst. C.E., who, in the autumn of last year, visited South Africa on behalf of the promoters of the Association, provisional contracts have been entered into for the purchase of the undertaking of the Port Elizabeth Gas Company, and for lighting King William's Town, both in Cape Colony.

At present Cape Town and Port Elizabeth are the only towns in South Africa which have a gas supply.

Negotiations have been opened by Mr. Corbet Woodall with other towns; and there is reason to believe that further contracts of a favourable nature will be concluded, in which event the Association will have the benefit of those contracts.

PORT ELIZABETH.—This is a considerable town of 13,000 inhabitants, and a port second only in importance to that of Cape Town. The Gas-Works have been established for over 20 years; and the Company has been earning large profits. A new Manager of much experience was sent from England at Christmas last, and has already brought about marked improvements in the working.

The Works are in excellent condition, and are equal to the

production, storage, and distribution of more than twice the present maximum requirements.

The Company has acquired the Works for £36,000 (which includes the provisional agreement for the King William's Town concession and the preliminary expenses), in addition to the value of the coal in stock.

KING WILLIAM'S TOWN.—This is a thriving town, about 40 miles from the coast, having a population of about 6000, and the centre of a large up-country trade. It contains good public buildings, churches, stores, &c. The Municipal Council have provisionally agreed to grant the exclusive right to open the streets for the purpose of laying gas-mains for a period of 25 years, and to take gas for lighting the public roads at a remunerative price.

The cost of erecting works and laying mains in this town, as estimated by Mr. Corbet Woodall, will not exceed £18,000; and it is confidently anticipated that the revenue derived therefrom will be sufficient to enable a dividend of 10 per cent. to be divided upon this capital.

The only contract which has been entered into is as follows, viz.:—A contract dated the 24th of October, 1888, between Mr. Corbet Woodall, of the one part, and William Cash, as a trustee for the Company, of the other part.

It is the intention of the Directors to apply for a Stock Exchange quotation at the proper time.

Prospectuses may be had of the Bankers, or of the Brokers, or at the Offices of the Company.
The Memorandum and Articles of Association can be inspected at the Offices of the Solicitors.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, DECEMBER 4, 1888.

ORNAMENT IN ENGINEERING WORK.

SOME short time since the American engineering press contained an account, in the usual "spread-eagle" style, of a wonderful piece of work that had been done in a locomotive engine-shop at Altoona, consisting in the erection of a locomotive and finishing it ready for steam in 16 hours and 50 minutes. This loudly-blazoned triumph of American mechanical engineering was criticized in *Engineering* as being somewhat too theatrical to really merit admiration. It was pointed out in the English print that a little previous arrangement will enable very ordinary people to perform very sensational feats in the way of despatching work; and the writer might have quoted the instance which so greatly interested our grandfathers, of a coat being made complete from the fleece on the sheep's back in a single day. The key to apparent miracles of this kind, which are at bottom mere conjuring tricks, is the preparation; and in engineering work

the meaning of the word completion as applied to a particular job is open to various interpretations. The Americans who put their engine together in less than 17 hours, of course started with a good deal of the heaviest work already done. The boiler was fixed on the frame, and the cylinders were in place. All the hoisting and lining-out had been finished, in short; and what was left was the assembling of the small pieces which had been already made to gauge. Thus in the same way the period required for "completing" any work will depend greatly upon the point of starting. In the example of the Forth Railway Viaduct, which has been in progress for years, and will yet take a long time to complete, the time will come when, by the placing of a last beam, and the closing of the last rivet, the great undertaking will be finished. By making a special effort, a great deal of this final work could be done in a very short time; but it would be an abuse of language to claim any special credit for thus expediting the "completion" of the work. So argued the writer in *Engineering*, and wound up his critical remarks by stating that, after all the heavy and particular work is done, it does not require much time to turn out a locomotive "resplendent with brass and paint." This last phrase has called forth a rather smart rejoinder from an American correspondent, who points out that the day is long past when locomotives in that country were usually smartened up in the fashion alluded to. They are all thoroughly, but soberly painted; and there is no brass. The writer goes on to say: "We are here becoming very sensible in matters of machine design; and I think that we can teach you in England a good lesson in the plainness and smoothness of machinery. Why," he asks, "do Doric and Corinthian architectures still flourish among the designers of your town water-works pumping-engines?" and so on to the same effect. We are reminded in reading this bit of satire, of the ridicule which we have on former occasions poured on the Siena marbled station-meters, and the ornate temples for enshrining these "things of beauty," with which well-meaning but inartistic gas managers attempt to relieve what they feel to be the dinginess and ugliness of their manufacturing stations.

The reappearance of this reproach in connection with machine design in general reminds one how deeply seated is the love of ornament in the human breast. The lowest savage may perforce dispense with clothing and ignore the advantages of cleanliness; but he must have his bead necklace and his tattooed skin decoration. And so it is up to the modern engineer, who in designing a beam engine makes his central pillar into the similitude of a fluted Doric column, and in erecting a gasholder disguises his cantilevers under architectural adornments borrowed from Corinthian temples. Drive the manifestation of this tendency under the surface in one place, and it breaks out again at another. If we forbid the gas engineer to make his gasholder look what Joe Gargery calls "much too architectooralooral," he will smarten up his station-meter; and if we deprive him of this solace, he will do something to the ridge and ventilators of his retort-house. Somewhere and somehow he will pay this homage to the tastes of his ancestors, unless all remnants of the transmitted propensity are purged out of him by severe discipline in the cold verities of Art. Most of us have need to watch over ourselves in matters of design, to see that we offend not in respect of unnecessary, ill-placed, or incongruous adornments. We can all smile at the florid decorativeness of the Renaissance, when natural philosophy was being painfully equipped with the apparatus which has done so much to unlock the secrets of the universe. If we look into any account of the origin and development of a particular philosophical instrument or pursuit, such as the telescope or ballooning, we cannot fail to be struck with the elaborate ornamentation, as contrasted with the intrinsic crudity of design of the early forms of these appliances. An old microscope was engraved, and fluted, and embossed with Medusa heads and festoons of fruit and flowers, which made it an extremely costly toy; while the vagueness of its defining power prevented it from being much more than an ornament. Half the cost of Montgolfier's balloon must have gone in the decoration of it by paint and gilding. This exuberance of ornamentation was toned down by degrees, although it yielded ground very stubbornly, and clung tenaciously to every part which seemed to harbour it. Thus, as the microscope was improved, ornament was banished from the tube to the stem and pillar—foliations and arabesques giving place to rings and lines, until at last all attempt to trick out the instrument was abandoned, and the makers grew content to take their

chance of the beauty that comes of fitness and good material well put together. The great solace is that this reward is nearer than seekers after ornament can realize. The truer a thing is to type, the more obviously designed with intelligent regard to its nature and office, the better it is finished—so much nearer is it to beauty. It requires high training or keen natural sense of beauty, or both, to appreciate this truth in its fulness, so as to rely upon it in deed as well as in thought. Unfortunately, we English as a people are anything but artistic, and Americans are no better. Some Continental and Oriental peoples have a true feeling for Art; but it is, naturally, confined to objects that have afforded opportunities for the growth of this feeling through past generations. Thus the Tyrolese will build a wooden cottage that it is a pleasure to look upon, just as naturally as he takes to playing the zither. The Briton of a similar class would never think of attempting to do either one thing or the other. The uninstructed Russian peasant makes and paints pretty as well as useful wooden articles which an artist delights to place upon his mantelpiece where he can have them before his eyes; while the English cottager buys of a hawker the most hideous earthenware dogs and horses, for chimney “ornaments.” It would be useless to ask the Tyrolese or the Russian to design a gas-bracket; for such an object would come from without the world of his sympathies and experiences. It is we inartistic British people who have originated steam-engines, gasholders, iron viaducts, and the host of other ngly modernities that harmonize so badly with pretty old-fashioned things; and when in our ignorance we try to break the shock of the contrast by “ornamenting” our harsh utilitarian creations with features borrowed from the older life, which was before these came, the result is an abominable monstrosity. If we let our work-a-day constructions alone, they are not always so utterly bad. We have, as a people, a sense of the proportion of the members of machines which is not to be seen in much of the best foreign work; and we make the best and neatest finish permitted by our materials, and required for the purposes intended to be served. No mechanic can compare British and (say) French workmanship in machinery, without noticing the difference in the styles in which such work is turned out of hand. When we build a gasholder, every plate is flattened, and every rivet regularly placed, although few people may see the work after it is done. In such towns as Berlin and Vienna, on the other hand, the windows of shops occupying the ground floor of magnificent blocks of buildings in the principal thoroughfares may be observed closed with miserably-made iron shutters, constructed of sheet iron buckled in all directions, so that work which we should be ashamed to put in a corner of an obscure gas factory our neighbours tolerate upon their house fronts. Let us then be content with that which we can do, and resign all attempts after what is beyond our reach. If the gasholder framing is taut and well proportioned, let us not sigh after ornate finials on columns or rosettes at the intersections of girders. If the station meter is well built and safely housed, it will not be improved by disguising it as a sarcophagus. Unnecessary ornament, when confined, as it must be, to particular spots, only makes the rest look nglier and more forlorn, like a diamond ring upon a dirty hand or a gold chain festooned across a shabby waistcoat. It may be hoped and believed that a sense of this truth is surely, if slowly, making its way among British engineers.

THE PARLIAMENTARY NOTICES FOR NEXT SESSION.

In another column will be found the list of notices given for the Private Bills relating to the supply of gas, water, and electricity which are to be submitted to Parliament next year. The measures relating to gas make a very poor show indeed. Only seven Bills in all mention gas supply; and there is not one of even second-rate importance, to say nothing about a higher class. The most interesting notice is that of the West Ham Gas Company; and the interest of this lies chiefly in the fact that the Company are asking for an extension of the amalgamation provisions of the City of London Gas Act, 1868, so that they may be enabled to unite, under the terms of the Act, with any neighbouring Company. It may be judged from this statement how meagre the crop of new Acts is likely to be, when this little scheme of a London Suburban Company has to be cited as the most striking notice of the whole list. Nor does inspection of the notices for Provisional Orders reveal any prospective activity of the Board of Trade by way of compensation for the poverty of Bills. Seven Orders are to be applied for, all by small Companies; and a

body of Improvement Commissioners intend to move the Local Government Board for powers to purchase gas-works at present in private ownership. On the whole the parliamentary outlook is dull in the extreme. Electricians are moving a little, as we notice in another column; the relaxation of the transfer clauses of the Electric Lighting Act having inspired speculators with the desire to make fresh attempts upon the investing public. If the legal aspect has improved in their eyes since this time last year, however, other circumstances are not more favourable. It may be mentioned that the Metropolitan Board of Works have given notice of their Bill for regulating the position of gas-mains in thoroughfares (as to which the views of the London Gas Companies are not quite in accord), in order that the County Council may be in a position to proceed with the measure if they think fit.

THE LAWRENCE GAS COMPANY AGAIN.

THE Lawrence Automatic Gas Company gave what is called a “private view” of their system of lighting to the usual knot of newspaper reporters on Wednesday last. Particular care was taken that no representative of the JOURNAL should be present, for reasons which we perfectly understand and fully appreciate. We had a look at the first display of this precious “invention” when it was shown in Fenchurch Avenue at the end of March last, and told our readers plainly what we thought about it. Since then we have had occasion to mention the subject again, *à propos* of the “puff” of the system which the Company have extracted from that celebrated expert, Dr. John Hopkinson, F.R.S., whose competency in such matters is attested by his confession that he had never previously heard of any arrangement for carburetting gas by volatile hydrocarbons vapourized without external heat! The Company have attempted to spawn some concessionary concerns, after the approved example of “Grandfather Brush;” but with what success we know not. Wednesday’s show, and the little lunch to follow, must have been intended to signalize the removal of the Company into Lombard Street. They will go a little farther yet, before they have done; for we do not entertain the slightest illusion respecting the fate of the Company. It will be kept afloat until some of those who are interested in it can “unload,” as the picturesque phraseology of the financial papers has it; and then it will sink like a stone. It is amusing to see how newspapers like *The Times*, which are popularly supposed to be well posted in regard to all matters of current interest, have reported Wednesday’s doings as though some of them had not published similar intelligence respecting the identical speculation months ago. As to *The Times*, one grows tired of pointing out how egregiously the Editor is misled by the people or person to whom he entrusts the preparation of paragraphs upon scientific matters; and nobody who ever saw the class of representatives that are sent by the conductors of London daily and weekly newspapers to demonstrations of this kind, could wonder at the rubbish they write respecting such subjects. These men might do very well at a fire, or the scene of a murder; but it is cruelly to expect them to write intelligibly—after a city luncheon, too!—about gas making. Yet these are the witnesses the Directors of the Lawrence Gas Company seek, instead of welcoming the criticism that comes from knowledge. Though we did not receive their invitation for Wednesday last, however, we willingly bestow this notice upon them. They may desire to exclude the unwelcome voice of warning; but it will not be silenced for all that, seeing that while the Lawrence Directors have their own object to gain by this practice of getting hold of ignorant press-men, we have also an end to serve, which is to prevent readers of the JOURNAL from falling into trouble. Meanwhile we notice that the great flourish made by the promoters of the Lawrence gas scheme has attracted another projector, in the person of a Mr. F. J. Lothammer, who also managed to get his wonderful invention described in *The Times*. This is, of course, a gasoline carburetter device, like the other, only the air is delivered under pressure, which is one more disadvantage. There will be plenty more of such schemes if the British public show the slightest tendency to “bite.”

A NEW SERIES OF PLATES ILLUSTRATING GASHOLDER DESIGN.

WITH this issue of the JOURNAL, we commence the publication of a set of drawings illustrating the large gasholder recently supplied for the Sydney Gas-Works by Messrs. C. and W. Walker, who are responsible for both the design and construction. It is a very creditable piece of work; and we publish it, with the description, in order to place it upon

record as one of the finest examples of modern gasholder construction. It is also a substantial proof of the material progress of the Australian colonies that they should now require such large provision for gas lighting in localities that but two, or at most three generations ago were wildernesses only lighted on dark nights by the bushmen's fires. And it does not appear as though any other means of artificial lighting that might be supposed to be able to supplant gas at the Antipodes has yet achieved sufficient success to alarm the Directors of the Australian Gaslight Company; seeing the splendid provision they are making for the future wants of the community which provides them with consumers of gas. At the present time, when the design of gasholders is very much before the attention of gas engineers, it is desirable that the actualities of construction should not be overlooked in the discussion of future possibilities. We cannot say positively what the gasholder of the future may be like; but we confidently recommend the subject of this notice as a first-rate example of the gasholders of the present. There is nothing strikingly novel about the design, which was indeed to be deprecated under the conditions; the holder being made in England and erected by the Gas Company's own workmen. It is all plain, straightforward design, realized in sound materials and good workmanship, such as any gas manager might be satisfied with. We understand that the holder is giving, in daily working; every proof of the excellence of its planning and execution.

Water and Sanitary Affairs.

ALTHOUGH not without importance, no very striking features offer themselves for comment in respect to the schemes coming before Parliament in the session of 1889, in connection with the water supply of the kingdom, and of which we give a complete list in our present week's issue. The Barrow Hæmatite Company, Limited, seek power to construct water-supply works, with power to transfer the same to the Corporation of Barrow-in-Furness. The Corporation, it will be seen, are going to introduce a Bill empowering them to construct new water-works, taking their supply from the River Duddon and elsewhere. The Hæmatite Company propose drawing from the Duddon and the waters of Crosby Gill. Bills are to be introduced for forming new Companies in some localities—including a district in East Kent, comprising Sandwich and other places, the works to be constructed at East Langdon; also for the supply of Bettws-y-Coed, Cwmdu, Llangeinor, and contiguous parts in Glamorganshire; the parishes and townships of Long Eaton, Sandiacre, and Stapleford, in Derbyshire and Nottinghamshire; and several small places in South Kent. Powers for the construction of additional works are sought by the Barrow Corporation, as already mentioned, as also by the Bristol Water Company, the Belfast Water Commissioners, the Corporations of Bury, Coventry, and Hythe, the Commissioners of the Deanhead Reservoir, the Eastbourne Water Company, the Kettering Water Company, Limited (who likewise propose a change in their legal status), the Newcastle and Gateshead Water Company, the Padiham and Hapton Local Board, the Plymouth Dock Water-Works Company, the Rastrick Water Company, Limited (to be transformed into a new Company), and the Yeaton Water-Works Company. An extension of time for works already authorized is sought by the Barrow Corporation in respect to works authorized in 1875; and by the Belfast Water Commissioners concerning works specified in their Act of 1884. The Wakefield Corporation seek similar relief for works authorized in 1880, including four reservoirs. The Swansea Corporation desire an extension of the time fixed by their Act of 1884 for the completion of the Upper Lliw reservoir and other works. An extension of time is sought by the Heywood Corporation in regard to a reservoir on Ashworth Moor. An enlargement of the statutory limits is proposed in several cases. Some of the Bills propose to regulate the employment of plumbers; Liverpool affording one instance. The misuse and fouling of water are the occasion of some preventive measures. The Corporation of Manchester seek for authority to alter certain lines and levels connected with their aqueduct from Lake Thirlmere to Prestwich. In London we meet with the Bill of the Metropolitan Board for regulating the laying of mains and pipes, and limiting the liabilities of Vestries and District Boards in the event of damage. The London Hydraulic Power Company seek to alter

some provisions of the Acts relating to their undertaking. The Rickmansworth and Uxbridge Valley Water Company propose to extend their limits so as to include Harmondsworth, Sunbury, Shepperton, and Littleton. New works are to be constructed by this Company, who also seek power to supply water in bulk to Water Companies and other bodies. The Corporation of Wigan have a somewhat ambitious scheme for extending the borough boundaries and absorbing the water undertakings of adjacent Local Boards. At Bury, Cleveland, and elsewhere, it is proposed that the charges for water shall be revised. The Huddersfield Corporation seek powers for the transfer to them of the property held by the Commissioners of the Wissenden reservoir. The Woodhall Spa Company desire to obtain the water-works situated in Lindley. There is thus a considerable amount of change contemplated, even though the individual projects are generally on a moderate scale. Among the more important schemes to which we have thus referred, attention might be called to the projects at Bristol and Newcastle. Further particulars concerning them are given in our "Parliamentary Intelligence." In each case a reservoir is to be formed by means of an embankment across a valley traversed by a river. It will be noticed that the Grand Junction Company are not proposing to re-introduce their Bill for drawing a supply of water from a source $3\frac{1}{2}$ miles above Windsor Bridge. The scheme has been highly commended by General Scott, the Metropolitan Water Examiner; but the ill-judged opposition offered this year in Parliament has frustrated the enterprise, despite its extreme importance to the Metropolis. So far, we have referred to the Bills which are to be brought into Parliament. In addition, there are a few applications to be made to the Board of Trade, which do not call for special remark at present.

THE NEW GAS MANAGER AT BATLEY.—The vacancy in the management of the Batley Gas-Works, caused by the removal of Mr. T. Holgate to Halifax, has been filled by the appointment of Mr. John F. Bromley, of Bolton.

THE SALFORD TOWN COUNCIL AND MR. ELLIS LEVER.—A meeting of the Salford Town Council will be held on Wednesday next, to consider, among other things, a communication sent to the Mayor from the Solicitor of Mr. Ellis Lever with reference to the resolution passed at the last meeting of the Council agreeing to the proposal of Mr. Lever as to the appointment of three members of the Council to whom he would disclose certain alleged frauds in connection with the Gas Department, which he now declines.

SACCHARINE.—Dr. Fahlberg, "the discoverer of saccharine," writes from Salbke, Westerhusen, to one of the Manchester papers, denying the truth of the allegation that coal tar saccharine is injurious to the human system. The origin of the statement, he says, is doubtless traceable to the report issued by the Commission appointed by the Conseil d'Hygiène et de Salubrité de la France, to inquire into the properties of saccharine, and also to the remarks made by Dr. Worms at a meeting of the Académie de Médecin in Paris, on April 10 last. The report, he avers, is objected to by all prominent men of science outside France, who have been consulted in the matter; that the words of Dr. Worms had become magnified and distorted by the French press, until they no longer represent what he did say; and that this distortion is malicious and is dictated by the fears of the French sugar industry lest sugar should be displaced. Dr. Fahlberg has delayed replying to the charges which have been made against saccharine pending the completion of experiments, impartially conducted, with a view to testing their veracity. Had they been confirmed he declares he should have discontinued the production or sale of saccharine.

THE LATE MR. JOHN COLLINS, OF BOLTON.—We have just learned some particulars as to the late Mr. John Collins, F.C.S., &c., of Bolton, whose death was briefly announced in our columns at the time of its occurrence. Mr. Collins, who was one of the most prominent Chemists and Gas Analysts in Lancashire, was born at Darton in 1832, and was educated at Chester College and South Kensington. He was identified with the gas industry all his life; and carried on an extensive practice, in association with his son, Mr. Walter H. Collins, Ph.D., F.C.S., &c., as an Analytical Chemist and Consulting Chemical Engineer, at Bolton. He was Chemist to the Ashton Gas Company, Gas Examiner under the Sale of Gas Acts for several Local Board districts in the neighbourhood of Bolton, Wigan, Liverpool, &c.; and he was at one time Chemist to the Bolton Gas-Works Committee and also Borough Analyst. He devoted a good deal of attention to water supply and pollution; and his experience of over thirty years in "scientific litigation" was very extensive. He was a familiar figure, as an expert witness, at Westminster and the new Law Courts. His health began to fail about three years ago, since which time most of his work has devolved upon Mr. Walter Collins. Mr. Collins was the originator of a most successful process for treating town's sewage, called the "M & C Process," in use at Bolton and elsewhere. His loss is felt by many gas engineers as a personal one. Those who were intimate with him find it difficult to name a man more equally or usefully accomplished. He had read deeply; and was a keen observer of men and manners in many countries.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 997.)

DURING the past week there has scarcely been any recovery effected in the Stock Exchange markets from the depression which characterized them the week before. From time to time there was a promise of some degree of rallying—according as more favourable views of the monetary position were formed; but it died away, leaving only fluctuation as the result. Still, on the whole, the week has closed rather better than it opened. Business in the Gas department may be written as decidedly quieter, especially in the Metropolitan Companies. Transactions in these have been marked at steady prices throughout the week, with very slight range of figures. Gaslight "A" has only varied from 251½ to 253. South Metropolitans have been quiet; and transactions have been mostly in the "A"—prices ranging from 300 to 301. For the "B," 235 has been the only price recorded; and the single transaction effected in "C" was at 246. In Commercial, the old stock has changed hands a few times at rather better than average figures; but it has not yet evinced that tendency to rise which we are inclined to believe is in store for it. All the Companies are, we believe, doing excellent business, not only in their residuals (the markets for which have greatly improved), but also in an increased sale of gas, which is the healthiest possible sign. Unless any abnormal circumstances and conditions of weather should occur to make this, the last month of the year, less prosperous than the rest, we shall expect that the accounts for 1888, when disclosed, will occasion a feeling of regret to those who have lately been parting with their stock. Among the Suburban Companies, Brentford has been done at rather easier prices; but the quotation is not affected. In the Foreign category, Continental Union, partly paid and preference, have advanced in view of the approaching improved dividend; and some Companies are quoted *ex div.*, at about equivalent figures. The Water Companies offer nothing particular to remark, except general firmness. Business in them has been very quiet; but some have made further advances in quotation. The only exception is Southwark and Vauxhall, the 7½ per cent. shares of which have lost the 2 that they gained the week before.

The daily operations were: Moderate business on Monday in Gas, mostly in the Metropolitan issues, without change of quotation. Water was very quiet indeed; but New River rose 1½. On Tuesday, business in Gas was more restricted; and again without change. Water was extremely quiet; but Kent improved 2. Wednesday's Gas business was only a shade more active, if at all, at previous quotations. A few Water stocks changed hands at good prices—especially East London, which rose 2; but Southwark 7½ per cent. relapsed to a similar extent. There was rather more doing in the Gas department on Thursday; but prices were only moderate. Water was quite stagnant. Friday was a very inactive day for Gas; but the figures recorded showed a very fair degree of firmness. Water again presented nothing to notice. Saturday's business in Gas was quiet, even for a Saturday; but the few prices marked were satisfactory. Continental new rose ½; and preference, 1. A little was done in Water; but all quotations remained unchanged.

ELECTRIC LIGHTING MEMORANDA.

THE COST OF ELECTRIC LIGHTING IN LONDON—PARLIAMENTARY NOTICES OF ELECTRIC LIGHTING VENTURES—FAILURES OF ELECTRIC LIGHTING IN GLASGOW AND PARIS.

LAST week we published a statement emanating from the House-to-House Electric Light Supply Company respecting the business which they contemplate doing in view of the immediate completion of their West Brompton lighting station. This statement calls for some comment. It will be noticed that in the first place the undertakers lay special stress upon the necessity for their being informed as to the maximum supply required by their subscribers. The importance of this direction becomes apparent when studied in connection with the experience of the customers of the Grosvenor Gallery Company, whose style of lighting is criticized in another column by an eminent correspondent. It is complained of the Grosvenor Gallery Company that they have taken on more subscribers than they are able to properly supply at the hours of greatest demand; and they accordingly have been driven to keep some consumers short while attending to others. The Charing Cross Railway Station has notoriously been made a convenience of in this way. Here the gas is always on; and when the electric lamps grow too dim, they are dispensed with for a time. When the Bond Street and Regent Street shops close, then the railway station gets its full current. Of course, the Grosvenor Gallery Company are not working under the restrictions of a Provisional Order, or these vagaries would not be permitted. The West Brompton station is not legalized either; but steps may be taken with this object, and the Company are wise to make sure of what they may be asked to maintain in the way of maximum supply during the heaviest hours of business. The Company's statements relating to the price of their supplies are worth noticing. By artfully manipulating the figures of imaginary rental accounts, they make it appear that incandescent electric lamps are to cost their customers but little more than gas at London prices. It is shown that 20 such lamps may cost for a winter quarter (reckoning five hours of lighting per night), the modest rental of £14 14s. 4d. Now this is equivalent to 46,000

cubic feet of gas for the same quarter, which at the same total cost would come to about 6s. 6d. per 1000 cubic feet. It is, however, waste of time to examine all these estimates. The best rule is that which we have already given in a previous issue: The price of electricity per Board of Trade unit, multiplied by 13, gives the equivalent cost of 16-candle gas.

The Parliamentary Notices, which appear in another column, contain several references to electric lighting. The Metropolitan Electric Supply Company seek powers by Bill for producing and supplying electricity in the parishes of St. James, Westminster, and St. Martin's-in-the-Fields, also over Waterloo Bridge and the Victoria Embankment. Then the Chelsea Electricity Supply Company mean to apply for Orders to enable them to commence business in the parishes of St. George's, Hanover Square, and Kensington. The Electrical Power Storage Company contemplate installations for the supply of Paddington and St. Martin's-in-the-Fields, and the Strand district. The Kensington lighting is to be scrambled for by the House-to-House and Kensington and Knightsbridge Electric Supply Companies. The London Electric Supply Corporation have given notice of their desire to occupy an enormous district extending from Chelsea to Whitechapel, and from Hampstead to Greenwich—all London, in short. In this ambitious scheme, they are rivalled by the Metropolitan Electric Lighting Company; and there are two smaller ventures, taking their names from Notting Hill and Westminster respectively, which are designed to pick up the crumbs that the others may leave in these parts. So that it will be seen how well provided London is to be with electric lighting in the near future—if all these schemes get successfully under weigh. This is, of course, a very big "if;" and we are a long way yet from the Royal Assent to all these projects. They will keep the Vestries busy for a few months, and give the new County Council something to think of.

The claims of electricity to be regarded as the safest of all possible means of lighting will not be helped by what happened on Monday last week at the Glasgow Post Office. About eight o'clock in the evening—just at the busiest hour, of course—all the electric lights went out, leaving the rooms in darkness. Soon it was reported that the roof was on fire. The fire brigade on the premises ran out their hose, and got the fire under with the assistance of the town force. It was found to have been caused "by some defect in connection with the electric lighting apparatus." For the rest of the night the building was lighted by candles. So the much-abused lights of other days have to be called in too frequently to supplement the defects of the light of the future. The incident is a serious one, not to be undervalued by those who wish to understand the exact position of electric lighting in this country. Professors pretend to cudgel their brains for reasons why electric lighting is not more prosperous than it is, yet somehow they always happen to forget these little mishaps, one of which does more harm to the prospects of electric lighting than a volume of lectures can repair. This class of misadventure is not confined to British electricians, for we read in the *Revue Industrielle* that the Paris Municipal Council Chamber and also part of the Hôtel de Ville have been lighted by electricity; and at the first sitting after this improvement had been completed, there was a sudden extinction of all the lights. Darkness cut short the business of the evening; and, no preparation having been made for such an eventuality, the municipal councillors were fain to find their way to the doors as best they might, adjourning their usually lively debate to the third day after. The electrical plant is fixed in the cellars of the Hôtel; and, naturally, all the arrangements of the lighting service are the best that money can procure. The occurrence is remarkable in connection with the fact that the Municipal Council have decided to embark in the business of electric lighting in the market quarter of the capital. Warnings against their undertaking any such business have been vainly addressed to them; and now they have been so dramatically reminded of the risks and uncertainties of electric lighting, people are asking the question how the Municipality can expect to do a satisfactory business of the kind in a large out-of-door district, when they cannot depend upon having a proper light in their own house? These considerations are not, however, likely to trouble municipal authorities bent upon spending public money in furtherance of their own ideas.

THE Directors of the Anglo-Spanish Gas Company have appointed Señor Francisco Ivern y Roig to be General Manager of their Játiva and Denia stations.

THE Directors of the West Kent Gas Company have appointed Mr. Albert Box to the post of Manager of the Erith works of the Company, vacant by the recent death (already announced) of Mr. Daniel Vincent.

NEXT Thursday, at 5 o'clock, there will be a meeting at the Sanitary Institute, Margaret Street, Regent Street, W., to hear a lecture by Sir Douglas Galton, K.C.B., F.R.S., on "The Future of the Amalgamated Societies—the Parkes Museum and Sanitary Institute of Great Britain."

THE Buenos Ayres Co-operative Gas Company have accepted the tender of Messrs. Gibbons Bros., of Dudley, for the erection of retort-benches at the new gas-works now in course of construction. The system of firing is entirely regenerative—as designed by Mr. G. Ernest Stevenson, C.E., the Company's Engineer—and consists of 32 beds of 8 retorts each, in four benches. The Company hope to make gas by Jan. 1, 1890.

DESCRIPTION OF A THREE-LIFT GASHOLDER FOR SYDNEY.

DESIGNED AND CONSTRUCTED BY MESSRS. C. & W. WALKER, ENGINEERS, OF LONDON AND DONNINGTON.

By the courtesy of Messrs. C. & W. Walker, we are able to present to our readers a series of actual working drawings used in the manufacture, construction, and erection of one of the largest and handsomest gasholders in the world. This gasholder was specially designed by Messrs. Walker for the Australian Gaslight Company, to be erected at their works at Sydney; and everything has been so arranged as to give the least possible trouble in erection—the Company themselves undertaking this part of the work.

It is, of course, obvious that a firm of engineers like Messrs. C. & W. Walker, who are constantly making and erecting gasholders, not only from their own designs but from designs by all the most eminent gas engineers of the day, must be in an advantageous position for determining the most economical and effective design to fulfil given conditions. So many gasholders pass through their hands that they can tell at once the best form to adopt to attain the maximum of stability with the minimum of work for the given capacity.

The gasholder we have to describe is a three-lift holder, of the following dimensions:—

	Ft. In.
Inner lift.	199 0 diameter by 40 feet deep.
Middle lift	201 6 " " "
Outer lift	204 0 " " "
Tank	206 0 " " "

The total capacity is about 3,750,000 cubic feet.

The guide-framing consists of 22 lattice standards of T section, connected by three tiers of warren girders, and diagonal ties. The tops of the standards are braced together horizontally by wind ties; and the whole guide-framing forms a complete, rigid structure, entirely independent of the gasholder bell for its preservation of form, and therefore able to give it perfect support and guidance in the operation of rising and falling.

The cost delivered f.o.b. Liverpool was about £11,000, or less than £3 per 1000 cubic feet capacity—a remarkably low sum, when the substantial character of the work is considered; and especially when everything was done to lessen the cost of erection, freight, &c.

General Principles to be Observed in the Design.

- I.—Gasholder to be erected, thousand of miles away, by strange hands. Necessary, therefore, that the difficulty and labour of erection should be reduced to a minimum.
- II.—In order to reduce "freight," the weight of the holder must not be greater than necessary.
- III.—For the same reason, the shape and size of the pieces in which it is sent away must conform to the shipping requirements.

These three points had to be borne prominently in mind; but are influenced greatly by the following considerations, or axioms, which affect the designing of gasholders generally:—

(1.) Saving weight in a structure does not always mean saving cost, because, to get the same strength and durability, the work and labour expended upon the manufacture and erection of a light, flimsy holder of complex form, may more than wipe out all the estimated advantages due to reduction of weight.

(2.) In many ways the less pieces there are to handle and connect in a holder, the less will be the cost; and if this can be attained by a little extra weight, it is a good compromise.

(3.) It is far cheaper to do as much work as possible on a low level where everything can be got at for rivetting, &c., and where every appliance is handy for doing the work in the cheapest form, and then lift the holder up in the bulk so to speak, than to build it up in fragments, piece by piece, towards the sky. It is also easier to get at it for inspection, sounder work is secured, and it is much easier to get everything plumb and true. This applies more particularly to the guide-framing.

(4.) As far as possible, special sections of iron should be avoided—viz., unequal sided tees or angles, and of unusual thickness and widths, as they entail extra cost, and are difficult to get rolled in a hurry. Sometimes a job is kept waiting a long time because the makers of the iron will not put in the rolls for an awkward section, which an engineer insists on having. Of course, there are special cases where it is an advantage to use an irregular section, where the strength or convenience of construction demands it.

(5.) A number of different sections of iron (angle, tees, &c.) should be avoided. As far as can be arranged, the same section should be used throughout the work—e.g., how often do we find gasholders with top purlins of several different awkward sections, when one or two at the most of some regular size would do. This rule is particularly necessary to observe in the case of channel and rolled joist iron, as they invariably take longer to get than ordinary bar iron. Moreover, if only a small quantity of several sections are ordered, the makers will not put in the rolls for them until they get orders for the same section, from other sources to make it worth their while; whereas with the same total quantity of one or two sections, there would probably be little trouble in getting them in good time.

(6.) One part should be the duplicate of another, or in other words everything should repeat itself as much as possible; and everything should be arranged symmetrically. For instance, the gasholder should be constructed in bays, corresponding in number with the number of columns or standards. By this

we mean that the number of pieces into which each ring, whether top curb, bottom curb, or hydraulic cups should be divided must equal the number of columns; and they should all be of equal length. The number of vertical stays, guides, &c., should also be a multiple of the number of columns. By this means every bay with its system of curbs, cups, dips, vertical stays, guides, rollers, &c., is repeated throughout the holder.

(7.) Welded joints and turned or joggled corners of angle or tee iron should be avoided where a substantial joint can be made in other ways. This will be understood when we come to consider the framed standards hereafter described, which are singularly free from unnecessary bending and welding of the iron.

(8.) Plates cut out in hollow curves should be avoided, as the pieces have to be punched out, which occupies much time. Thus to cut out the shaded piece in "A" it has to be done inch by inch, and then trimmed on the raw edge. It is far better to leave it

A.

B.

straight on the edge; for the value of the piece of plate saved is nothing compared with the trouble of cutting it out. Of course, plates can be sheared with convex curved edges without any trouble. For instance, cutting away the shaded part in "B" only requires a few strokes of the shearing-machine.

(9.) A great and unnecessary variety in the sizes of rivets or bolts should be avoided, especially in the same member or bar—e.g., it is often advisable to put a larger rivet through a bar in a certain place than is theoretically required to meet the strain upon it, just to agree with other holes in the same bar which are required to be of that size. Otherwise the bar has to be lifted, and brought to the punching-machine two or three times, when once handling would do. The extra weight of the rivet is a mere trifle, compared with the saving in labour of handling. Besides, to have but little variety in rivetting, prevents mistakes being made. If it be said that the iron is weakened by putting through a larger hole than necessary, then use a heavier section to compensate for the weakening; it will be saved over and over again in the increased facility with which the work can be executed.

(10.) Many things might be mentioned respecting castings, especially relating to cast-iron columns; but as they do not enter into the construction of this holder, it will not be necessary to lay down minutely the rules for guidance in designing cast-iron work. We may, however, mention that: (1) The taper of a cast-iron column should always be $\frac{1}{8}$ -inch to a foot. (2) The lengths of each piece should not exceed 16 feet, except for special reasons. (3) All mouldings should be well bracketed inside. (4) The metal should be thickened up round holes for bolts, &c. (5) Never cast a guide-rail or other large projections on one side of a column. (6) The practical requirements of the foundry as regards moulding, &c., must be observed. (7) Square based, high pedestals, on which to stand the shaft above, are very bad; they crack in casting from contraction strains. (8) Cast-iron lattice-work must be avoided; it is very treacherous.

(11.) The depth of a gasholder should, if possible, never be less than one-fifth of the diameter. Messrs. C. & W. Walker have, we believe, made the shallowest gasholders in the world—viz., 165 feet diameter by 20 feet deep, each lift; the depth in this case being less than one-eighth of the diameter. From their experience, they assert that it would be absolute waste of material to make them any shallower; indeed, they should never have been this depth (as the expense was greatly increased thereby), if it had not been for very exceptional circumstances.

We will now give a description of each of the working drawings as they appear, calling attention to any details of special interest and give the reasons for the construction adopted.

DRAWING No. 1.

The Inlet and Outlet Pipes.—These are 3 feet diameter, and constructed of wrought-iron plates, made in handy lengths with angle-iron flanged joints, faced. The duck-foot bends and tees, however, are made of cast iron, as wrought-iron duck-foot bends and tees are very expensive to make. It is worth noting that the duck-foot is cast in separate pieces from the bend; the reason being that it avoids the cracking from contraction strains. In fitting together, there is the least possible work in chipping, as little snugs are cast on, which alone require trimming; the joints are also caulked up solid with borings to make a sound job.

Holding-down Bolts and Plates.—These are 2½ inches diameter, and about 16 feet long. There is no swelling up at the thread, because it is better to make the bolts larger in diameter (for their entire length) to allow for weakening due to screwing; and thus save the weld. The foundation plates are built solid in the brick-work; flat iron being used in preference to a large casting, as the latter destroys the continuity of the brickwork of the tank too much by cutting it away. For the same reason the foundation bolts are made with heads, instead of cotter ends, as cotters require large recesses to be left in the tank to get them in after the tank is built.

Tank-Guides.—The wrought-iron tank-guides are of channel iron

bedded flat against the tank wall all the way up, to avoid springing, and are attached by wings and Lewis bolts to the stones let in the tank walls. This is all clearly shown on the drawing.

Livesey Man-Lid.—Drawing No. 1 also gives a detail of the Livesey man-lid, which is coming very much into use, especially in large holders, as it admits of ready access to the inlet and outlet pipes inside the gasholder when the holder is at rest, without discharging all the gas contained in the crown of the holder. The construction shown is as effective and simple as it is possible to make it.

ELECTRIC LIGHTING STATIONS.

DURING the last few months a considerable amount of public interest has been aroused by reports of a prospective revival of enterprise in electric lighting from central stations. This was of course, the system upon which the pioneer electric lighting companies of ten years ago were supposed to work; and we all know how they fared. Then for some years past central lighting stations were only talked about between electricians as among the certainties of that future to which they have always looked with undimmed hope. But their only real business meanwhile was with special installations for lighting single buildings, or groups of buildings, and steamships. Yet through all this period of discouragement, the lamp has been kept burning in one or two places. There have still been a select few who would not give up the idea of distributing electricity for lighting like gas, and disdained to join in the scramble for isolated lighting installations in which others were fain to seek their livelihood. Now these persevering experimentalists seem to be forging their way to the front once more. The Electric Lighting Act has cleared the road for them, to a certain extent, and capital appears to be forthcoming to test the practical question whether the last ten years of probation have really weeded out weaknesses from the various surviving systems of electrical distribution. Mr. Killingworth Hedges has recognized the moment as an opportune one for the publication of a little work descriptive, from an ostensibly impartial standpoint, of these systems.* He confesses also to having another object—that of persuading British gas companies to “follow the example of the American companies, and take up the business of supplying electricity.” And as Mr. Hedges is a well-known writer on the subject of electric lighting, with some pretensions to be esteemed an authority upon electrical engineering, we are prepared to seriously examine his arguments.

In his preface, Mr. Hedges admits that the actual result of the application of scientific knowledge and large capital during the last ten years to the art of lighting by electricity, “appears to be discouraging.” He thinks, however, that “the era of central-station electric lighting, which has now commenced, ought to re-establish the position of electricity in financial circles, and afford a safe and profitable outlet for the surplus capital of the investor who buys gas and water shares to pay 4 per cent.” This passage is not so clear as could have been desired. It might be asked, for instance, in what sense the era of central-station lighting has “now” commenced? We have already shown that this was the purpose claimed by the companies which started, in the first years of the decade, with the expectation of driving gas lighting out of the kingdom. We are not aware that there exists any justification for the claim that there is at the present time anything more than a revival of interest in this subject, due in great measure to the amendment of the Electric Lighting Act. The demonstration of the scientific and commercial success of the idea which, with the ineradicable precipitancy of electricians, Mr. Hedges writes of as a fact, is something which remains to be proved. Mr. Hedges begins his book with a general explanation of what is meant by the term “Central-Station;” what such an establishment may be expected to do as a matter of work; and how it is likely to be supported. He then goes on to deal with the method of charging for electricity; and here he becomes misleading. In the first place, he does not explain the Board of Trade unit in a way that a non-technical consumer could understand; indeed, it is as much as we can do to follow him. He states that the Board of Trade unit is 1000 watts per hour, and that a 16-candle power Swan lamp is assumed to require 60 watts, which permits his readers to understand that 16 $\frac{2}{3}$ such lamps can be kept going (theoretically) with a consumption of one unit of current, which he says is supplied in England from 1s. to 7d. by different contractors. Now, 16 $\frac{2}{3}$ statutory gas-burners of 16-candle power will consume 5 cubic feet per burner per hour each, or altogether 83 cubic feet of gas per hour, which is consequently the equivalent of a Board of Trade unit of electricity. Therefore the ratio of the unit of electricity (which, as we see, equals in lighting effect 83 cubic feet of gas) to the usual unit of 1000 cubic feet by which gas is sold, must be as 83 : 1000, or a fraction ever one-twelfth. To find the equivalent price for gas, to give equal light, to electricity quoted at per Board of Trade unit, we must multiply the latter by twelve. Hence electricity at 1s. per unit is equivalent, light for light, to gas at 12s. per 1000 cubic feet. Mr. Hedges makes it 6s. 10d. Will he kindly explain how he gets at this figure? Even our calculation is scarcely fair to gas, for Mr. Hedges admits that Swan lamps require in practice about one-sixth more power than theory prescribes; and, further, that a 20-candle power lamp must be used to give the 16 candles actual illuminating power, so that his statement of equivalent values

is still more erroneous. Mr. Hedges would probably admit that the cause of electric lighting has suffered sufficiently in the past from exaggerated statements of its value as compared with gas; yet here, in the very opening of his new book, we detect him in an altogether misleading comparison, as flagrant in its way as the “French measurement” of illuminating power introduced and adhered to with such effrontery by the Brush Company. For the guidance of our readers, we have been in the habit of computing the Board of Trade unit of electricity as equal to 100 cubic feet of ordinary coal gas. Thanks to Mr. Hedges, we shall in future multiply the price of the unit by 13 to arrive at the true equivalent, unless he can correct us in this matter.

We cannot follow the author through all his descriptions of systems and plants, most of which are borrowed from published lectures and papers, and tell little or nothing that has not been already conveyed to our readers through our ordinary reports of such matters. For a subject that, according to the author's claim, is to be taken as the record of a scientific and commercial success, he has singularly few data to offer. All his statements of capital and working expenses are mere estimates, or apply to foreign or isolated examples, and not one of them can be cited as illustrating the financial circumstances of an English central electric lighting station. So far as we are informed, the Grosvenor Gallery people are the sole possessors of reliable information upon this head; and they are distinguished for keeping their knowledge to themselves. Mr. Hedges has a chapter, which he would probably regard as of peculiar interest for our readers, headed, “The Interests of Gas Companies as to Electric Lighting.” It begins with the statement that “the policy of gas companies with regard to electric light has, with few exceptions, been a state of indifference to the progress of things electric, with contempt for a rival whose opposition is not sufficiently powerful to be appreciated.” This, we venture to say, is altogether an error. Gas companies have looked upon “the progress of things electric” with much interest, since the memorable time when a Stock Exchange manœuvre sent their shares down to panic values. Mr. Hedges goes on to prophesy that the progress of incandescent lighting will infallibly displace gas lights; and he proceeds to argue that gas companies, being in a position which would enable them to acquire “almost as complete a monopoly of lighting by electricity as they have of gas,” should seize the opportunity. He employs the example of the Imperial Continental Gas Association in Vienna, and gas companies generally in the United States, to prove that electric lighting and gas can be satisfactorily supplied together. With much of his argument we agree. If it is possible to supply electric light well and cheaply, it can be done from gas-works, where fuel may be had at the minimum of cost, and the best experience in distribution is available. With Mr. Hedges's deduction, however, it is impossible to concur. Gas companies are undertakings for supplying gas, not electricity, with which they have no more warrant for concerning themselves than they have for selling petroleum. If electric lighting from central stations is ever made successful, it will not be by gas companies; and if money is lost in it, it will not be money subscribed on the faith of the gas business. Even if the idea recommended itself to gas shareholders (which it does not), local authorities would rightly object to such an expansion of the gas interest. Mr. Hedges knows little of the circumstances and motives of local authorities in the United Kingdom if he really believes that “a very little expenditure” would enable gas companies to enlarge their powers in the direction he contemplates. We do not presume to judge the conduct of American gas companies, whose circumstances differ radically from those of English gas undertakings. It would doubtless be very agreeable to electricians if gas companies everywhere would take electric lighting in hand, but it would be folly to encourage any delusions upon this point. Such a thing is not to be looked for in this country, where gas lighting is so settled by statute that the public are partners of the undertakers, which is not the case in any other part of the world.

On the whole, Mr. Hedges's book may be found a useful compendium of the information respecting its subject which may be regarded as generally available at the present time. The author has no original experiences to narrate, and has not discovered any useful secrets; but he is a very fair chronicler of other engineers' projects and reports.

At last night's meeting of the Society of Chemical Industry, Mr. A. H. Allen read a paper on “The Analytical Examination of Water for Technical Purposes.”

The County Justices of Suffolk have appointed Mr. G. Hodson, M. Inst. C.E., of Loughborough, to advise them upon the water supply of their asylum at Melton.

Last Friday week, Mr. Thomas Canning, Assoc. M. Inst. C.E., Engineer and Manager of the Newport (Mon.) Gas Company, was elected a member of the Town Council for the Central Ward of his borough.

TELEGRAPHIC information has been received that the formal contract for the acquisition of the Do Beer's Consolidated Mines Water Supply Act by the Kimberley Water-Works Company, Limited, has now been signed.

At the recent municipal elections, Alderman Samuel Haynes, Managing Director of the Lichfield Gas Company, was elected Mayor of the city, and his son (Mr. George Haynes) was elected High Sheriff of the City and County of Lichfield.

* “Central Station Electric Lighting, with Notes on the Methods used for the Distribution of Electricity.” By Killingworth Hedges, M. Inst. C.E., &c. London: E. & F. M. Spon, 1888.

Notes.

THE ADULTERATION OF COAL TAR NAPHTHA.

In a further note to the *Chemical News* (see *ante*, p. 934), Mr. Thomas T. P. Bruce Warren gives the following results of some ordinary commercial products, so as to show the value of the method he suggested:—

Designation of Liquid.	Iodine absorbed Per cent.	Remarks.
Benzol, 90 per cent. . . .	1.911	
Toluol, commercial . . .	4.046	Mean, 3.429 and 4.679 = 4.054.
Naphtha, solvent	3.808	Sp. gr. 875 at 15.5° C.
„ product, 142° C. . .	3.429	Sp. gr. 869 at 15.5° C.
„ „ 160° C. . . .	4.679	68 per cent. Sp. gr. 870 at 15.5° C.
„ „ residues	4.246	29 per cent. Sp. gr. 900 at 15.5° C.
„ with 10 % benzoline . .	5.742	3 per cent. Sp. gr. 750 at 15.5° C.
Benzoline	20.980	Sp. gr. 797.
Paraffin oil, white . . .	4.864	
Shale spirit	44.900	

The iodine absorption of the original naphtha was 3.808 per cent.; the absorption calculated on the products was 3.801 per cent. The addition of 10 per cent. of benzoline to the same naphtha should have given a calculated absorption of 5.525 per cent. The addition of petroleum products will, says Mr. Warren, evidently increase the iodine absorption. The specific gravity of the mixture with 10 per cent. of benzoline was 863 at 15.5° C.

THE DISTRIBUTION OF FRICTION IN STEAM-ENGINES.

Professor Thurston read a paper, at the last meeting of the American Society of Mechanical Engineers, upon the distribution of internal friction in steam-engines. In this he stated the results of a number of experiments conducted by himself and others under his direction. The idea of the experiments was to ascertain how the observed total friction was made up by the addition of the friction of the various sliding parts; and the method adopted for carrying out the investigation was by determining the total internal friction of the engines selected for testing, and then disconnecting the moving parts one after another, driving them separately from some other source of power. In this way it was ascertained that in a so-called "straight-line" engine, with a 6-inch cylinder and 12-inch stroke, working with a slide-valve, the internal friction amounted to 2.389-horse power, distributed as follows:—In the main journals, 35.4 per cent.; in the eccentric strap, 4 per cent.; in the crank-pin, 5.1 per cent.; in the crosshead, 4.1 per cent.; in the valve, 26.4 per cent.; in the piston and rod 25 per cent. In a new 12 inch by 18 inch "Automatic" engine, the main journals took 41.6 per cent.; the valve and valve gear, including eccentric, took 9.3 per cent.; and the piston, crosshead and crank took the remaining 49.1 per cent. It was found that the friction of all the engines tested was practically the same under all conditions of loading; even a compound engine exhibited substantially the same internal friction at all loads up to its full rated power, and also without any load at all. Several engines showed a different distribution of friction at different rates of speed; but the variation was in all cases slight. Consequently the writer concludes, as a general deduction, that in all ordinary forms of the steam-engine, and under all common conditions of working, the internal friction of the machine is practically invariable under variation of useful work, and is very nearly independent of piston speed.

THE MIXING OF CEMENT CONCRETE.

A recent number of the *Deutsche Bauzeitung* contains a contribution upon the subject of Portland cement concrete from a well-known German authority, Herr Dyckerhoff. The main purport of this communication is to emphasize the fact that careful mixing of the ingredients of concrete is tantamount to saving cement, seeing that a comparatively small proportion of cement thoroughly incorporated with the broken stone and sand is much more effective than a greatly increased quantity less perfectly mixed. For ordinary foundations, Herr Dyckerhoff recommends one part of cement to from six to eight parts of sand or gravel, or from eight to ten parts of broken stone. Where the substructure is likely to be subjected to heavy shearing stresses, these proportions should be slightly reduced—say, to one of cement to five or six of gravel. In cases of very important works, the writer recommends the carrying out of preliminary experiments to determine the best proportions of cement and sand, employing samples of the same sand that is intended to be used in the work, because sands differ very much in constitution, and often a dull and comparatively poor-looking sand will give much better results when tested in this way than sands of brighter and better appearance. This remark does not apply to the case of sands clearly containing clay. In the preparation of concrete the cement should not be measured but weighed. The sand and cement should be mixed dry in a wooden trough, and turned over three or four times with a spade, before any water is added, after which it is again to be thoroughly worked over until it forms a homogeneous and slightly damp mass. The broken stone, gravel, &c., which has been carefully washed and is still damp is then added; and the whole is thoroughly re-worked, so as to cover every fragment of stone with a coating of the cement, which is a point of the first importance. Care is taken to prevent the stone working to the top during the transit of the concrete from the mixing-table to the site where it is to be deposited, and

equal care is taken in depositing it in the trenches. For finishing off the surface of work, Herr Dyckerhoff uses a cement mortar composed of 1 part of cement to 2½ parts of sharp sand; to which, if the sand is very coarse, 0.1 part of fat lime is added, which makes the mortar spread more easily. Of course, old work is very carefully washed before the mortar is applied.

DIFFERENTIAL CHARGES FOR ELECTRO-MOTORS.

In a contribution to the New York Convention of the National Electric Light Association, Mr. H. C. Lufkin states that where motor energy is distributed by electrical currents, it is found more convenient to differentiate between the uses of power for various purposes, than to charge a uniform rate per horse-power delivered. Thus, for example, fans used in the ventilation of hotel dining-rooms and restaurants, being only required for a short time during the day and for a few months in the year, are charged at the highest rate for the horse-power required. The highest rate is also charged for working open tank elevator pumps for passenger use. An important source of business in connection with electric motor service is sewing-machines. In some cases the machines are driven from counter-shafting actuated by a comparatively large motor; and in others every machine has its independent motor of about ⅓-horse power—the latter being the more profitable system to the supplying company. It is stated that a company can make in the United States a better profit than out of lighting by lending out sewing-machine motors and supplying them with current at an average charge of \$1.25 per month. Picture-frame makers and moulding manufacturers are good customers to the electric power-supplying companies, and so are nickel and silver platers and polishers. Printers frequently take the electrical power for one or two job presses; and laundries are profitable. Coffee grinders, manufacturing jewellers, opticians, dentists, and church-organs are all in Mr. Lufkin's list, which illustrates the need experienced by modern town communities for small and convenient motors in substitution for manual labour.

The death is announced of Mr. Thos. Wheatley, Secretary of the Greenhithe and Northfleet Gas Company at the age of 40 years.

The Directors of the Abergele Gas and Water Company have appointed Mr. J. W. Wilson, of Crossgates, near Leeds, to be Manager of their works.

It has been decided to light the town of Puerto Real, near Cadiz, by gas; and the proprietor, Senor M. Diez y Carrera, has placed the order for the necessary plant, &c., with Messrs. Gibbons Bros., of Dudley, who expect to have all in readiness to light the town about the beginning of next March.

The greatest pressure recorded at the Forth Bridge during the gale on Friday, the 16th ult., was 27 lbs. per square foot on the large board of 300 square feet area, 41 lbs. on the small fixed, and 35 lbs. on the moveable boards. On the island of Inchgarvie are placed three wind-gauges or pressure-boards; the larger one, 300 square feet in area, is fixed square to the east and west winds, and of the two smaller ones of 1½ square feet area, one is fixed as above, and the other is free to swivel square to the wind in any direction. The wind, being south-west, did not strike the fixed board at right angles. At the other parts of the bridge, an average pressure of 32 lbs. per square foot was recorded. A pressure of 56 lbs. per square foot has been allowed for in the bridge calculation.

An interesting and most successful *conversazione* was given last Friday week by the Oxford Junior Scientific Society; the *élite* of Oxford society and learning being present in the Museum to listen to the lectures of Professor Milnes-Marshall, on "Animal Pedigrees," and Colonel Gourand, on Edison's new phonograph. Among the many interesting objects exhibited were a fine group of regenerative lamps of various kinds erected by the Oxford Gas Company. These included the "Wenham," the "Cromartie," and the "Schülke" lamps; the latter being shown in three sizes of 25, 15, and 4 feet per hour consumption. One of these was placed in a most trying position—opposite the entrance door, through which a furious gale was blowing; and those versed in such matters were struck by the remarkable steadiness of the flame under such difficult conditions. The whole display was a remarkable one, as showing the highest development which lighting by gas has reached at the present time.

A USEFUL recipe for a cement for stopping cracks in stone or brickwork is published in the *American Wood Worker*. The basis of the preparation is old paint scrapings from kegs, the skins formed in old paint pots, or any similar refuse which contains oil and zinc or other mineral. The mass is to be steeped in some cheap oil, and heated, if necessary, until soft enough to be capable of being stirred into a homogeneous paste, when it should be reduced by the addition of a little more oil, and then worked through a sieve, and ground in an ordinary paint-mill. A quantity of common whiting is next to be worked into the oil and paint, exactly as in the manufacture of putty; but the paste of whiting, oil, and paint should not be so tough as common putty. When the whiting has been thoroughly mixed in, and the mass well worked over, add a quantity of Portland cement, just sufficient to bring the paste to a consistency that permits ready handling. Cracks in brick and stone work puttied up with this mixture will be effectually stopped. The mixture sets, and hardens like iron, becoming impervious to moisture, and unaffected by any range of atmospheric temperature.

Technical Record.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

The Seventy-sixth Quarterly Meeting of this Institution was held last Saturday, at the Victoria Hotel, Manchester. The PRESIDENT (Mr. Thomas Duxbury, of Darwen) occupied the chair; and there was a fair attendance.

The HONORARY SECRETARY (Mr. Harrison Veevers, of Dukinfield) read the minutes of the last meeting, which was held at Doncaster, on Aug. 25 last, and they were unanimously confirmed.

NEW MEMBER.

Mr. J. C. Ingham, Manager of the Ramsbottom Gas-Works, was elected a member of the Association; on the motion of Mr. W. Woodward (Bury) seconded by Mr. J. DALGLIESH (Glossop).

ELECTION OF PRESIDENT.

The next business was to elect the President for the year 1889-90; the election, according to rule, preceding by three months the actual time of entering on the duties of the office.

The PRESIDENT remarked that the gentleman who was to succeed him in the chair was one who would fill it with credit to himself and honour to the Institution.

Mr. WOODWARD said he had a very pleasant duty to perform in proposing the election of Mr. T. Banbury Ball, of Rochdale, as President for the ensuing year. He did not know any member of the Institution who would fill the position with more credit to himself and to the Institution than Mr. Ball. His bearing and general manner towards the members of the Institution had been such as to make him many friends. His election would be a popular one; and he did not doubt that his occupation of the chair would give satisfaction to the members generally.

Mr. W. W. HUTCHINSON (Barnsley), in seconding the proposal, said that Mr. Ball's professional ability entitled him to the highest honour which the Institution could confer, while his integrity and gentlemanly bearing were qualities calculated to bring credit on the Institution.

The PRESIDENT observed that he wished to echo every word which the mover and seconder of the resolution had said in regard to Mr. Ball. That gentleman had had considerable experience in the management of Gas Institutions. He had been on the Council of The Gas Institute, and seen how things were there conducted; though, whether he had seen anything there to emulate might be a matter of opinion; still, he was a gentleman who would, as President, be calculated to enhance the interests of the Institution, if he retained his health. They were sorry that his health had not been all that they or he could have wished; but they were glad to have him amongst them, and they would do credit to themselves in electing him President of the Institution.

The resolution was carried by acclamation.

Mr. BALL remarked that no one was more fully aware than he himself of the few merits which he had to recommend him to their selection as President of the Institution. During the past year, occupying as he had the post of senior Vice-President, he was sorry to say that his attendances had been very few and far between. This, however, had not been his fault. It was partly owing to the fact that the works he had to superintend required a great amount of personal supervision. This was an experience known to many of them; for the technical assistance afforded them was, in many instances, of the most meagre description, and absence from home could not therefore be undertaken without serious thought and consideration. This was one of the reasons which had prevented him attending as often as he could have wished during the past year. By their kindly forbearance, these absences had been overlooked; and if his health was spared, he hoped, during his year of office in the chair, to pay better attention to the business of the Institution, and to attend oftener, so that at the end of the year he might deserve their confidence as he at present possessed it.

THE SECRETARYSHIP.

The HONORARY SECRETARY proposed an alteration in Rules 2 and 3, by the substitution of the words "two Honorary Secretaries" for "Honorary Secretary" in the places where these words occur. He said he suggested this alteration at the last meeting of the Committee, after filling the office of Secretary for nine months, and with an intimate acquaintance with the Institution from the commencement. The suggestion was not a new one with him; for he had advocated the appointment of a senior and junior Secretary for many years. The work at the meetings was—as Mr. Hutchinson, the late Secretary, would bear him out—really too much for one man. The issuing of circulars was a serious matter, for 120 of them had to go out four times a year; and this, with the engagement of rooms, and looking generally after the arrangements for the meetings, was too much for one gentleman to do with any degree of comfort. Then when the Secretary retired, a new man came who knew nothing about the work. If the resolution he proposed was carried, there would be two Secretaries. The senior Secretary would look generally after the conduct of business, and the other undertake the drudgery and detail work, and qualify himself for the senior position when it became vacant. He did not advocate this from any selfish motive, because his term of office was drawing to a close. He thought, however, that if The Gas Institute had done much the same thing, and had an Honorary Secretary as well as a paid Secretary—though he did

not advocate anything in the nature of payment here—it would have been very much better for the parent association. He had brought forward this proposal merely to see whether or not the members approved of it.

There was no seconder to the motion; and the President announced that, as this was the case, the proposal fell to the ground.

GENERAL BUSINESS.

The members then proceeded to discuss Mr. Dalgliesh's paper on "Oil and other Illuminants and their Effect on the Consumption of Gas,"* and Mr. Newbigging's paper on "Gasholders without Upper Guide-Framing,"† both of which were read at previous meetings. A report of the discussions will appear in next week's issue of the JOURNAL.

The PRESIDENT, in the absence of Mr. T. Newbigging (who, as announced in last week's JOURNAL, is on his way to South Africa), read a paper prepared by that gentleman, entitled "The Presence of Water or Moisture in Coal, and its Effects." This communication is given elsewhere to-day; and, on the motion of Mr. DALGLIESH, seconded by Mr. W. W. HUTCHINSON, the discussion was postponed until the next meeting.

The PRESIDENT, before closing the proceedings, took the opportunity of expressing, in the name of the Institution, their pleasure at seeing present Mr. Henry Woodall, the President of The Gas Institute. They were, he said, always glad to see the heads of the profession at their meetings, and to learn from the experience they had gained in the past.

Mr. WOODALL, who was received with applause, thanked the members for their kind greeting, and said he really ought to apologize for being so late. He came too late to contribute anything in the way of discussion. It was his loss that he was not present to hear the discussions; but it was his misfortune, on that and previous occasions, to have had business which had delayed him in another place until their meeting was well advanced. He was glad, however, to be with them; and it was always the greatest possible pleasure to him to be where gas managers assembled.

The members afterwards took tea together.

AMERICAN GASLIGHT ASSOCIATION.

THE ANNUAL MEETING IN TORONTO.

Having already noticed the proceedings on the first day of the annual meeting of this Association, held in Toronto last October, we proceed to give an account of those on the second day.

The first paper read was written by Captain Ross, of Cincinnati, and consisted of a description of his steam-stokers and improved charger. He remarked at the commencement, that the subject of working retorts by machinery was not novel; it had occupied the attention of some of the brightest and most intelligent gas engineers. Coming to his own apparatus, he said that the system of injecting coals into the retorts by means of steam had been objected to, as not capable of evenly distributing the coal, which might be packed at the front so as to prevent the free egress of gas; and it was stated that the concussion incidental to the blast might fracture weak retorts, or cause a variation in the seal. Questions had also been raised as to whether the condensed steam would not moisten the coal; and whether the weight of the charge could be properly adjusted. In reference to these objections, he said that by intelligently directed blasts, the coal was deposited in the retorts exactly as it would be by shovels; the first portion going to the end of the retort, the second striking on the first, and so on, thus securing even distribution. As the front part of the hopper did not cover one-half the superficial area of the mouthpiece, it was evident there could be no pressure inside the retort during the act of charging. A series of tests at the works of the Cincinnati Gas Company had proved that practically the seal was not affected; and in no single instance had a retort ever been blocked. Of course, a careless operator might distribute the coal irregularly, just as he might with the scoop or shovel; but, with the Ross machine, all the charging would be done by one man, who could be held responsible for its efficiency. Of the total volume of steam used, not exceeding 10 cubic feet could be retained in the retort; and this represented an insignificant quantity of moisture. The hoppers were gauged by ascertaining the number of cubic inches occupied by any given weight of coal to be charged, and the weight of each charge could be adjusted as easily as with the scoop. At the Cincinnati Gas-Works, the difference between the weight of the coal actually put in, and that calculated by theory, during a period of six months, was only 1½ per cent. Captain Ross next proceeded to describe the discharging machine, the construction of which is generally known, and passed on to a detailed description of the steam charger which he admitted was not perfect when first introduced, but had since been greatly improved. The working pressure was 60 to 80 lbs. per square inch, and three retorts could be charged concurrently in 5 seconds. From practical experience, he could say that, under the most unfavourable circumstances, the depreciation would not exceed 5 per cent. per annum. As evidence of the practical working of the machinery, some letters from well-known gas engineers were read. The first was from Mr. Keenan, Engineer to the Cincinnati Gas Company. At the East-end station, a pair of these machines were used for a stack of 224 retorts, charging every 5 hours with 333 lbs. of coal per charge. This required 45 retorts

* See JOURNAL Vol. L., p. 1091.

† See ante, p. 373.

to be drawn and charged per hour, and the work was usually done in 40 minutes, by a staff of 10 men, who worked 12-hour shifts. There were also one furnace man, three coke men, and four coal men, making a total of 18. There was one man on the discharger, two on the charger, and the remainder acted as lid men. The average yield of gas was 5·07 cubic feet per pound, representing a production of 908,000 cubic feet in 12 hours. From the results of several months' operations, it was found that the average cost, including wages, fuel, water, repairs, and sundries, was about £8, or 2·1d. per 1000 cubic feet of gas. The cost of effecting the same work by manual labour in the usual manner would be about £18, or 4·7d. per 1000 cubic feet. At the West-end station where the drawing machinery only was used, the cost was 3·1d. per 1000 cubic feet, as compared with 5·2d. under the old system. Mr. Keenan thought the Ross apparatus might be advantageously applied in any works using not less than 8 benches of sixes. He did not consider the depreciation exceeded that of hand tools; and the system had not injuriously affected his retorts. Letters from several other Engineers, including Mr. T. Forstall, of New Orleans, General Hickenlooper, of Cincinnati, and Mr. M. S. Greenough, of Boston, all certifying to the effect that considerable economy had followed the use of the machines, were also read.

After reading the paper, Capt. Ross replied to several inquiries. He said that the apparatus could be worked in a ground-floor retort-house; and a space of about 16 ft. 6 in. wide in front of the retorts was all that was really necessary. He preferred to use overhead store-bins for the coal; but these need not be higher than the level of the top of the charger. The discharger weighed 8 tons 10 cwt., and the charger 7 tons. Mr. G. Shepard Page said that the subject of stoking by machinery presented three aspects—philanthropic, as dispensing with hard work; prudential, as a remedy against strikes; and financial, as a means of reducing working expenses.

A paper on "Gas Coals, with Special Reference to Provincial Coal," was read by Mr. J. D. Perkins, of New York. After a few remarks of a general character, he gave a sketch of the early history of the subject in the United States. They were first discovered by Nicholas Denys, in 1672, at Cape Breton; and the first attempt in the way of regular mining was made in 1720 in the same locality. For some time after the first establishment of gas-works in the States, the principal supply of gas coal was imported from England. Even down to 1855, the only gas coal raised in the States was that from the Albion mines at Pictou, so that one company held the monopoly of it. Full details as to the establishment of the principal American gas collieries were next given, together with some details as to the working results and quality of the products. From these it appears that the Pennsylvania gas coals, on the average, yield 11,800 cubic feet of 16½-candle gas, and 15½ cwt. of coke per ton; and the Cape Breton gas coals, 10,800 cubic feet of 15½-candle gas, and 15 cwt. coke.

Mr. J. R. Smedberg followed with a paper entitled, "Observations during Many Years Experience in the Gas Business." Commencing with the year 1853, he remarked that exhausters were then matters of debate, clay retorts were unknown, and a favourite setting at Cincinnati, where he was then engaged, was one of three iron retorts. A Box washer, set next to the hydraulic main was considered to yield better results than a jet washer. The guide columns of Jeffreys great single-lift gasholder were handsome Corinthian shafts arranged in groups of three, and also adapted to serve as atmospheric condensers; and in small works the centre-mast gasholder was not uncommon. A yield of 4 cubic feet of gas per pound of coal carbonized was considered good work; and stoppages from naphthalene were rare. Mr. Smedberg proceeded to give an account of a number of interesting personal reminiscences relating to troubles experienced and overcome. In the course of the American War he ran out of coals and could not obtain a supply, so had to fall back on wood gas; and it was stated that a cord of ordinary fire-wood would furnish nearly as much illuminating material as that obtained from a ton of the best Pittsburg coal. A cord of dry oak was said to yield 16,000 to 17,000 cubic feet of 27-candle gas, consisting of 30 per cent. hydrogen, 33 per cent. marsh gas, 6½ per cent. hydrocarbons, and 26 per cent. carbonic oxide; and having a specific gravity of 0·580. Pine wood was found to yield a gas consisting of hydrogen 33 per cent., marsh gas 21 per cent., hydrocarbons 10½ per cent., carbonic oxide 27 per cent., and carbonic acid 5 per cent.; the specific gravity being 0·663. After this he began to make gas from the splendid light wood of Southern Georgia, producing 10,000 cubic feet per retort per day, or from 24,000 to 36,000 cubic feet per cord of wood, according to the quality. At Bluff, California, many years later, he found that the average cord of Sierra Nevada pitch pine weighed 3189 lbs. and yielded 21,000 cubic feet of nearly 17-candle gas. The volume, character, and behaviour of the product were largely modified by the amount of moisture present in the wood, the form and temperature of the retort, the weight and duration of the charge, and the kind of burner employed. He had found that the Hartley shale or Wollongongite of Australia yielded 14,000 cubic feet of 80-candle gas per ton.

Consideration of the "Question Box" was then proceeded with. In reply to the question, "What is the extra cost on wear and tear of meters where iron purification is used," Mr. Somerville said that the use of oxide certainly had the effect of stiffening the diaphragms of the meters; but he could not say what the extra cost was, though he believed it to be an important item. Mr. Scrivener felt warranted in saying that the use of oxide did not injure the meters at all. Mr. Young had not observed that the

use of oxide affected the meters in any way. Another question was: "What is the best way to treat men who are overcome by coal gas?" Mr. Clarke referred to a recipe given by a prominent physician, recommending that the man be laid on his back without the head raised, in the fresh air away from a crowd, that the clothing be loosened at the neck and waist, and a little brandy and water administered. A teaspoonful of a mixture of one part aromatic ammonia to 16 of water to be given every two or three minutes. The face and chest to be slapped with the wet end of a towel; and warmth and friction applied if the body or limbs were cold. If the breathing was feeble or irregular, artificial respiration should be used, and persevered with so long as there is any possible hope. Oxygen might be administered. Mr. White had been told by a physician that the best plan was, if the man was sensible enough to swallow, to give a tablespoonful of olive or common sweet oil. This might be followed by milk, brandy, or other stimulant. He had followed this plan in conjunction with the rules as to fresh air, loosening clothes, &c., as mentioned by Mr. Clark, for some years with success, and had had personal experience of its efficacy. Mr. Somerville remarked that the effects of coal gas soon passed off; but water gas seemed to influence the blood, and it was some weeks before it was got rid of. He would be glad to hear of a remedy for water gas inhalation.

A brief conversation subsequently took place on the "Advantages Gained by using Naphtha of High Specific Gravity in the Manufacture of Water Gas," on "Sunday Labour," and on the old bugbear "Naphthalene in Mains and Services;" but no new theories were advanced by any of the speakers on these questions. After the usual votes of thanks had been passed to the officers of the Association, the meeting terminated in the manner already detailed in our columns a few weeks since.

THE PRESENCE OF WATER OR MOISTURE IN COAL AND ITS EFFECTS.

By THOMAS NEWBIGGING, C.E., of Manchester.

[A Paper presented at the Quarterly Meeting of the Manchester District Institution of Gas Engineers, Saturday, Dec. 1, 1888.]

In my first paper, read before this Institution some time ago,* on the subject of "Water," I dealt with that substance *per se*—its physical character and effects, and its constituent gases and the properties of each. On the present occasion, I propose to speak of water in connection with the manufacture of coal gas. The part which water or moisture plays in the economy of gas manufacture is important and wide-reaching. Its presence is useful and even indispensable under certain circumstances; whilst in others it is highly objectionable. Let us now trace it throughout its various manifestations.

The spontaneous combustion of coal when stored in a dense mass, in a wet or moist condition, is a not unusual occurrence in the experience of gas managers. I do not know whether any of the members present have been unfortunate enough to have added this experience to their other qualifications; but if they have, I am sure they will be ready to admit that it is one of the most undesirable occurrences that has overtaken them during their professional career. I have had one experience of the kind; and the vivid recollection of it remains with me to the present hour. For several days I perceived in the retort-house a disagreeable smell, which produced a kind of sickly and choking or smothering sensation as I drew breath. At first, being inexperienced as to the cause, it did not strike me that anything was wrong, though the phenomenon was unusual and unaccountable. The objectionable smell continuing, and even becoming more pronounced, it suddenly dawned upon me that spontaneous combustion in the coal had taken place. A close examination of the heap of material (to the amount of about 1500 tons) stored in one of the adjacent coal-stores confirmed my suspicions; and without delay I had about a dozen men employed in reducing the thickness of the heap at the place where it appeared to me the fire was smouldering. The labour of getting down to the source of the mischief was one of great difficulty, and even danger. The centre of the mass began to give off suffocating and deadly fumes in considerable volume; and for hours the men toiled at the work—some of them being so far overcome as to be compelled to desist, and seek the open air to recover their breath. The fire had spread like the roots of a tree in every direction from the centre of the heap, and was only extinguished with difficulty, by deluging it with water from a hose-pipe which I called into requisition. Many tons of the coal were charred, and rendered worthless so far as gas making was concerned; and the sulphurous odour hovered about the premises for days after.

There is this liability to spontaneous ignition in almost all bituminous coals of a friable nature. It is due to more than a single cause. It may arise from the condensation of oxygen within the pores of the carbonaceous particles, just as oily cotton-waste will fire spontaneously in the same way by the rapid absorption of oxygen. According to Professor Abel and Dr. Percy, water or moisture does not accelerate, but rather retards spontaneous ignition under these circumstances. The danger of firing is greatest with those coals which contain a large proportion of iron pyrites in the shape of nodules, or "brasses" as they are called, and which are stored in a mass in the wet condition. These "brasses" become oxidized by the atmospheric oxygen dissolved in the water with which the coal is saturated; and the heat thus generated raises the coal to ignition point. The moral, of course, is to

* See JOURNAL, Vol. XLVIII., p. 1016.

avoid using coal of this character, which is costly in other respects; and if it must be used, then care should be taken to hand-pick the pyrites as far as possible, and to store the coal in a dry state, or otherwise to adopt means of thoroughly ventilating the mass with a swift current of air. Unless the ventilation is thorough, the admission of air will do more harm than good, as a sluggish current will not reduce the temperature, but rather tend to develop and increase it.

When coal is exposed to the weather, being stored in the open air without any protecting covering, it is not only liable to be wetted by rain on its outer surface, but it also absorbs and retains moisture within its structural interstices. Bituminous or gas-producing coal, from its comparatively soft or friable texture, is especially affected in this latter particular. Cannel, by reason of its close-grained and harder character, does not absorb water or moisture in the same degree. The effect of this excess of moisture in bituminous coal is to produce disintegration, reducing the size of the lumps, and converting them to a considerable extent into dust and culm. The exposure of the coal in the winter season in this climate is, of course, the most objectionable as regards disintegration. In hot climates the intense heat of the sun produces disintegration. The ill-effects of this absorption of moisture do not end there. Oxidation of the particles of the coal also ensues; and as this is only another name for *eremacausis* or slow-burning, the material is not only reduced in weight, but its gas-producing power, both as regards quantity and quality, and its coking qualities, are greatly impaired. This is the common experience of gas managers; and the desirability, and even the necessity—if good and satisfactory results are to be achieved—of providing covered storage room for the coal is therefore very generally admitted, and acted upon.

When coal in a wet or moist condition is placed in the retorts to undergo carbonization, the results are unsatisfactory in several respects. In the first place, the temperature of the retorts is reduced; and, as a consequence, extra fuel is consumed in restoring the temperature, and in drying the coal by evaporating the moisture, and driving it off as steam before the coal is in a fit condition to undergo destructive distillation.

If the mischief caused by the wet or moist coal ended here, it would be tolerable. But it does not. A portion of the moisture or steam is decomposed in contact with the sulphide of iron (FeS) produced by decomposition from the bisulphide of iron or iron pyrites (FeS_2) contained in the coal. The oxygen combines with the iron, forming the oxide of that metal; and the hydrogen with the sulphur, producing sulphuretted hydrogen. Bisulphide of carbon is also formed in considerable volume. In this way the whole of the sulphur present in the coal is caused to pass off into the gas, and has to be subsequently removed in the process of purification; thus increasing the cost of manufacture. On the other hand, when the coal is distilled in the dry state, rather more than one-half of the sulphur present is left behind in the coke.

These are the principal drawbacks attending the presence of water or moisture in connection with gas manufacture. In a future paper, I hope to point out the advantages which the gas manager derives from the use or presence of water under other conditions.

COWAN'S "SYPHON" WATER-METER.

Habitual readers of the JOURNAL will not need to be reminded of the two series of letters that have recently appeared in our "Correspondence" columns—one series during the last few weeks, and the former one the early part of the past summer. As the outcome of the discussion, we are to-day enabled to publish an illustrated description of the "Syphon" water-meter, patented by Mr. William Cowan, of Edinburgh; remarking that an examination of the instrument itself will show that no-one need have any difficulty in fully understanding it. The principle is so simple, and the construction and action are so open to view, that prejudice is likely to be disarmed, and confidence inspired in the mind of the observer.

The water is measured in the two equal compartments of what is practically an open box or trough. Over the central division of this box hangs a reciprocating funnel, which receives the water passing from the ball-valve, and conducts it into the compartments alternately. In each of these chambers there is a syphon, the outlet end of which projects through the bottom of the chamber, and so discharges the contents each time the water attains the level at which the syphon becomes charged. The measuring capacity of each chamber is the quantity it is capable of containing between the level of the surface of the water which remains after the syphon has acted, and the higher level which had to be attained before that action could begin. The meter is practically two syphon chambers acting in combination, so as to be filled and emptied alternately; and, in being so emptied, to give an accurate register of the water they discharge.

The motion of the shaft which suspends and reciprocates the funnel, originates in the alternate discharge of the syphons. It will be observed in the illustration that, below the syphon outlets, there is a beam which has a bucket on each of its ends; and that the buckets are so placed that the end of the beam, which at the time happens to be "up," has its bucket enclosing the projecting end of the corresponding syphon. In this position, therefore, the bucket receives the first water the syphon passes; and consequently that end of the beam is made to descend whilst, by the same action, the opposite end and bucket are raised so that they may be similarly operated upon when the other syphon begins to discharge.

The result is a reciprocal motion of the beam, which is transmitted (by two connecting rods) to the beam above, which moves the funnel shaft and operates the index.

The primary purpose of the bucket-beam is to produce the motion which reciprocates the funnel and moves the index. But, in addition to this, the buckets serve the useful purpose of temporarily "sealing" in the water they receive, the outlet ends of the syphons. The seal so produced is suddenly withdrawn when the bucket descends; and thus aids the syphon action, especially when small streams or mere droppings are all that the chamber is receiving from the ball-valve. But for this provision, a mere stand-pipe action might be produced, and continue without charging the syphon. In the largest size of meter, a plunger hangs over each chamber from a beam on the funnel shaft. This beam, having the same reciprocating action as the others, lowers one plunger and raises the other each time the beam moves. The immersion of the plunger, just as the chamber has become filled, raises the water therein and charges the syphon.

The buckets also act as compensators for the slightly reduced quantity the chamber contains when supplied by mere droppings, as compared with its contents entering in a full stream. It will be readily understood that when the stream is large, the chamber is rapidly filled, and the syphon completely and easily charged. The bucket then is thrown down by the mere force of the water, with-

out being necessarily filled to its full capacity. In this case the bucket has nothing to do with the measurement, which is all effected in the chamber by the syphon. But it is otherwise when the water in the chamber rises very slowly; for in this case stand-pipe action, into the bucket, precedes the full action of the syphon. This has the effect of filling the bucket with water before it is thrown down; and this extra water in the bucket, on these occasions, compensates for any deficiency in the chamber, which the slowness in the supply may have produced. In this way it is that small streams and mere droppings may be as accurately measured by this meter as the largest quantity it is intended to pass.

The adjusting ferrule on the ball-rod is for the purpose of adapting the maximum passage through the valve to the power of

the meter. It will be readily understood that a valve which might be large enough to give the necessary supply when the pressure is 100 lbs., would be much too small for a pressure of 10 lbs. But meters must be made suitable for use under varying conditions of pressure; and, therefore, the adjusting ferrule is employed to restrict, or to enlarge, the maximum opening, so as to ensure that the maximum pressure can never pass into the meter more water than the meter is able to deal with. As lower pressures can have no disturbing effect, it is only necessary to employ the ferrule against that which is the highest, in the locality and position where the meter is fixed. In order to facilitate the adjustment of the ferrule, the ball-rod is marked with a scale which shows the proper positions of the ferrule in regard to several pressures.

Alluding to his invention, the patentee (to whom, of course, we are mainly indebted for the above interesting account of his meter) says: "If popularity has been denied to the gas-meter, it has chiefly been because so few persons have been able to understand that much abused apparatus. To an ordinary gas consumer, his meter is as mysterious as his watch; but, whilst the watch may be proved to be correct or incorrect by the man himself, the meter must be tested by others, and its accuracy ascertained by means the consumer can rarely be got to understand. If meters for measuring water are less unpopular than meters for measuring gas, it is not because the former are more easily understood; but, rather, because they are less generally used. In their varying constructions and principles, as well as in their actions, water-meters have hitherto been as much beyond the understanding of most consumers, as gas-meters of all kinds have been and are. So far as gas-meters are concerned, it is not likely that these instruments will ever be brought within the easy and complete comprehension of the ordinary consumer. But, as regards water-meters, there can be no doubt that this has been already accomplished in the case of the 'Syphon' water-meter.

"This meter, being on the low-pressure principle, is usually placed over the cistern; and, therefore, at the end of the service-pipe. In this latter respect, its position resembles that of a gas-meter; and this, of itself, ought to be a sufficient vindication of the arrangement which places the water-meter over the cistern. The meter, therefore, receives through its ball-valve the water the service pipe supplies; and passes it, after measurement, into the cistern below. But the distinguishing feature of this meter—in addition to its novelty and simplicity—is its power to measure every drop of water that passes from the ball-valve. There are persons who profess to think this a matter of little importance; but, if it be worth while to use meters at all, it is surely desirable that the measurement should be as effective in regard to small droppings as when large quantities are being delivered. When it is kept in view that most of the water used is passed into cisterns, it cannot be doubted that such meters as are incapable of recording the smaller streams and droppings which pass from the ball-valve, are very unsatisfactory instruments. The absurdity of using 'high-pressure' meters because they may be interposed in the line of main or service-pipe, and do not materially lessen the pressure, must be apparent in all those cases—and they are the vast majority—where the destination of the water is a cistern. If the fact were sufficiently borne in mind, we should hear less of the superior advantages of high-pressure meters, and water authorities would be more ready to consider the claims of any meter on the low-pressure principle which might be found capable of dealing effectually with the difficulty of measuring water into cisterns."

CALCULATING THE FLOW OF WATER THROUGH PIPES.

At the Convention of the National Association of Master Plumbers held a short time ago in Boston (U.S.A.), a paper was read by Mr. E. Murphy, of New York, on "Simple Methods of Calculating the Flow of Water Through Pipes." The paper has since appeared, and from it we make the following extracts.

Mr. Murphy began by explaining that the subject he had chosen was one which had for years possessed unusual interest for him; but he found it was not easy to procure the information he desired—the formulæ being so forbidding and inscrutable as to baffle all hope of his ever being able to solve them. He wished to discover some simple practical rules for finding the quantities of water discharged from pipes of varying diameters and heights, and from long lines of pipe at a distance from the main or reservoir; when account must be taken of loss arising from friction; how to calculate the volume of water discharged from aqueducts or sewers when the size and fall are given; the losses arising from using pipes of insufficient size in supplying tanks; and other matters of interest to an engineer concerned with the supply of water.

Before entering upon the main subject of his communication, the author briefly explained the laws of gravitation, according to one of which solid bodies fall 16 feet in the first second. He pointed out, however, that the velocity of the falling body at the end of the first second is 32 feet, because, starting from nothing, and the motion being gradually accelerated, 16 is the average between 0 and 32. Another of these laws is that, by squaring the number of seconds during which a body falls, and multiplying by 16, the total number of feet fallen can be told. Thus: In two seconds a body falls 64 feet, two seconds squared and again multiplied by 16 will give 64; and three seconds squared and multiplied (9×16), 144—the distance the body falls in three seconds. Another law is that while the distances fallen increase in one proportion, the time or the seconds advance in another, and the velocity in still another. The velocity attained in the first second

is increased by adding 32 feet for each succeeding second. Thus: For the first second velocity, 32 feet; for the second, 64 feet; and for any other second, 32 multiplied by the number of seconds. He then proceeded as follows.

In hydraulics, velocity is the chief factor to be determined in every problem. The rule for finding it is written thus:

$\sqrt{2gh} = v$. Although it looks suspiciously learned, it is simple in its application, and easily remembered. It means: Multiply 2 by 32 by the given height and extract the square root, and the velocity in feet for one second of time is found. In this formula g is the acceleration of gravity, or the velocity in feet per second acquired by a falling body in one second of time. This, as we have seen, is 32; and h is the height. Water will issue from an opening in the side or bottom of a tank or reservoir with a velocity equal to that attained by a body falling freely through a space equal to the perpendicular distance of the centre of the opening below the surface of the water. For example, in a cistern filled with water 25 feet deep, if we make a circular opening one inch in diameter at the bottom, we find the velocity thus, according to the formula $\sqrt{2gh} = v$; that is, $2 \times 32 \times 25 = 1600$; extract the square root, and the velocity for one second is found to be 40 feet. This rule applies to all bodies falling freely in space. The calculation is simple, with probably the exception of the extraction of the square root.

Having found velocity, the next step is to find quantity. Multiply velocity by the area of the orifice, and we find it would fill a pipe one inch square and $31\frac{1}{2}$ feet long in a second; and consequently $31\frac{1}{2}$ feet for one second becomes, by multiplying by 12 for inches and by 60 seconds for one minute, the number of cubic inches discharged in a minute, which, divided by 231, the number of cubic inches in a gallon, gives the discharge in gallons for one minute. The process is as follows:—Multiply velocity 40 by $\cdot 7854$ (area of 1-inch circle), which gives $31\frac{1}{2}$ feet nearly; $31 \times 12 \times 60 = 22,680$ (cubic inches), divided by 231, and 98 gallons is found to be the quantity discharged per minute. While this is the theoretical amount, it varies under certain conditions. If the orifice is cut in a thin plate, the amount would be about two-fifths less, or 38 per cent.; and if the orifice is prolonged by a short tube 3 or 4 diameters, the amount is increased another fifth, or 19 per cent.; and if the interior of the opening is rounded into a conical form, the amount is increased to within 3 or 4 per cent. of the calculation.

In calculating the amount of water delivered through long pipes, account must be taken of two kinds of loss: (1) Loss occasioned by cross currents and shape of the edge of the orifice, and (2) loss by friction. The latter is the principal, and nearly the only one considered. The friction of water on smooth surfaces is about $\frac{1}{2}$ lb. per square foot when water is moving at the rate of 10 feet per second. If the velocity is increased or diminished, the friction increases or diminishes in proportion to the square of the velocity. The proportion is as follows:—As 10 feet squared (= 100) is to 20 feet squared (= 400), so is $\frac{1}{2}$ lb. to 2 lbs. So that doubling the velocity increases the friction fourfold; and if the velocity is increased to 30 feet per second, the friction is increased ninefold. According to this, then, if a 1-inch tap be connected with a 2-inch pipe under any given head, the velocity is reduced to one-fourth, because the space in the 2-inch pipe being four times greater than the 1-inch, the water necessarily moves four times slower, as only the same quantity is passing through both. Hence, as the velocity in the 2-inch pipe is reduced to 1-4th, the friction is reduced to 1-16th of what it was in the 1-inch pipe. Besides, as the surface of a 1-inch pipe is twice as great as that of a 2-inch pipe containing the same quantity of water, and as friction is according to the extent of the surface, it may easily be seen that friction in the 1-inch pipe is 32 times greater than in the 2-inch. It is owing to this fact that pipes of the same length and head will deliver water according to the $2\frac{1}{2}$ power of their diameters; that is, a 2-inch pipe will pass nearly six times, and a 3-inch pipe nearly sixteen times, as much water as a 1-inch.

I will now give the rule for finding the quantity of water delivered through pipes of any length, diameter, and head. The formula is: Multiply the constant 425 by the diameter in inches multiplied by the pressure per square inch; divide by the length, and extract the square root to find the velocity. *

$$\sqrt{(425 \times d \times p) \div l} = v.$$

I will take the former example ($425 \times 1 \times 11$) $\div 100$, assuming the length of pipe to be 100 feet from reservoir or tap. The pressure in pounds per square inch is found by multiplying the decimal $\cdot 43$ by the head ($\cdot 43$ lb. giving the pressure for a square inch 1 foot high), $425 \times 1 \times 11 = 4,675$, which divided by $100 = 46\cdot 75$. Extract the square root, and it gives the velocity as 6.7 feet per second. This multiplied by the area $\cdot 7854 \times 12$ for inches $\times 60$ for seconds in a minute will give the number of cubic inches discharged ($6\cdot 7 \times \cdot 7854 \times 12 \times 60 = 3,787$, divided by 231) = 16 gallons nearly. This shows that in a 1-inch pipe 100 feet long, the quantity discharged is considerably lessened by friction.

Another useful rule for finding the velocity in pipes where the head is low (it is used a good deal by English engineers, and is credited to a Mr. Blackwell) is: Multiply head in feet per mile by diameter in feet, divided by 2.3, extract the square root, and the velocity is obtained. The remaining process is the same as mentioned before for finding number of gallons.

* The velocities found by this rule are about one foot per second less than those given by the Poncelet-Trautwine formula—

$$v = m \sqrt{d h \div (l + 54 d)}$$

in which m is a variable coefficient.

It may not be out of place here to point out the difference between, first, pressure in weight; second, pressure in square inches; third, volume discharged. If we assume a column 100 feet high and 1 inch square, the weight is 43 lbs., and the pressure is 43 lbs. per square inch. But you can make a column of water 100 feet high with only a pint of water, and the pressure at the bottom is still 43 lbs. per square inch. The volume of water discharged, however, from an orifice in the bottom of a tank 100 feet high is something altogether different. Thus in a tank of this height, and capable of discharging 1 gallon from an opening 1 foot from the top, the quantity discharged will not be as the height in pounds weight or in pounds per square inch, but as the square root of the height. In the case of the tank, 10 gallons will be discharged, or, as the square root of the head, 100 feet. So that knowing the height, we can easily compare the results to be obtained from orifices of different sizes. Thus it may be required to know what head a 2-inch tap will need in order to give as much water as a 1-inch tap with a head 6 feet high. As the 2-inch tap is four times larger, square it, and divide it into 64, and the answer is that the 2-inch tap with 4 feet pressure will deliver the same quantity of water.

Register of Patents.

STARTING GAS-ENGINES.—Bickerton, H. N., of Ashton-under-Lyne. No. 17,686; Dec. 23, 1887. [11d.]

This invention refers to the application of a small water-motor and connecting mechanism for the purpose of starting gas-engines. It is proposed to work the motor by the pressure of water in the ordinary water-supply mains. The motor is fixed to the bed of the gas-engine; and the ram is formed at its front extremity as a toothed rack for gearing with a spur-wheel mounted on the gas-engine shaft. This spur-wheel is not keyed direct to the shaft, but is in the form of an annular ring around the boss of the ratchet-wheel, or its equivalent keyed upon the driving-shaft, and which ring carries a pawl or clutch for engaging with the ratchet-wheel in one direction, but being free from it in the other direction. In this manner it is possible to impart two or more rapidly following strokes to the fly-wheel; and thus to keep up its momentum until the engine is fairly started. The ram of the motor is of less diameter than the cylinder, and is fitted at its back extremity with a cupped leather of the full diameter of the cylinder, so that the difference in area between the piston and cylinder can be utilized for bringing back the ram when the slide-valve is timed to open the communication with the exhaust.

GAS-LAMPS.—Thompson, W. P.; communicated by F. Deimel, of Berlin. No. 17,877; Dec. 29, 1887. [8d.]

This invention relates partly to a chimney for lamps, which when placed on a burner causes the flame to assume a spherical form like that of a regenerative burner.

Fig. 1 shows a vertical section of an Argand burner turned into a regenerative lamp by placing on the burner the new chimney. Figs. 2 and 3 show modified forms of the invention.

On the bell holder B of the Argand burner A (fig. 1) the glass globe C is placed, so that the usual flame is obtained. By placing the chimney D on the globe C, this flame is turned into a regenerative lamp. The chimney consists of the usual straight tube D, and of the chimney holder provided with a deflector hanging downwards. The holder can be used for the purpose of heating and leading to the upper part of the flame the fresh air required for combustion, and can then be made hollow; or it can be formed of one single plate having the shape of a saucer (figs. 2 and 3); or it can consist of a cross piece, in which case the air is heated by its contact with the chimney and led from the latter to the flame. If a hollow chimney holder is applied, its upper part is advantageously made of metal; whilst the lower part can be made of porcelain or enamelled metal. The latter is provided with air inlets; whilst the air is admitted at the edge of the globe, between the upper and lower part of the holder. The air entering the globe from the outside is compelled to pass into the highly-heated chimney holder, and comes in contact with its surface. Thence it is led to the upper part of the flame. The

deflector which hangs down from the chimney holder, is preferably saucer shaped, and so arranged as to present its hollow surface to the flame F. The gas issuing from the burner strikes against the deflector; and in consequence of the hollow in the deflector, the air rising upwards inside the flame, which has partly become mixed with gas on its way, is collected and heated. The combustion of the gas is, therefore, assisted; so that the flame assumes the appearance of a perfectly uniform ball. The upper part of the flame is supplied with air, which enters through the inlets in the chimney holder; the air having travelled between, and in contact with the sides of the holder. This effects a complete combustion of the gas and produces a "white bright lighting flame."

The method of obtaining a white flame in the new lamp chimney is therefore different, says the patentee, from that used in the regenerative lamp. The heated air for effecting the complete combustion of the gas is not admitted direct to the burner, but behind or above the place of ignition; and therefore the disadvantage of overheating the gas before its escape from the burner is avoided. The temperature at the mouth-piece of the burner is the same as is usual in gas-burners; and it cannot cause a decomposition of the gas. The combustion will gradually increase; and if a comparison with well-known burning devices be made, the working will be found to be similar to that of fireplaces provided with smoke consuming devices—that is, with a supply of air to the back part of the flame. In order to obtain a complete and uniform burning of gas and a noiseless flame, it is necessary to make an essential alteration in the introduction of the air to the burner itself. If gas-burners were to be used as they are in practice, there would arise whirling currents in the flame; and these currents are easily recognized by means of the wandering dark stripes they produce. In order to avoid these disadvantages, says the inventor, it is necessary to divide, as finely as possible, the air which enters from below into the globe holder, and admit it to the flame. This effect is obtained by placing a fine wire gauze net X in the globe holder B. A perforated plate does not fulfil the intended purpose, for the edges of the perforations cannot be made otherwise than sharp, so that the air flowing through them meets always with a resistance which prevents the uniform combustion of the gas. If, on the contrary, a wire gauze is used, the openings in the latter have all their edges rounded, and the air flows through the holes without meeting with much resistance.

MANUFACTURING GAS.—Meeze, A. G., of Redhill. No. 7097; May 12, 1888. [8d.]

This invention relates to the manufacture of illuminating gas "by the mutual decomposition of steam and hydrocarbon fluid in contact with suitable heated surfaces—such as deflecting and impact devices—of cast iron or other material, and by combining with the nascent gases and vapours of such decomposition, a suitable regulated proportion of natural gas, hydrogen, carbonic oxide, or a mixture of hydrogen and carbonic oxide, such as that obtained in the production of what is commonly known as water gas in a heated condition."

Fig. 1 represents a section of a through retort, containing a steam superheating coil, an ingression pipe, and deflecting and impact devices, and having attached, at opposite ends, a gas supply and a gas eduction pipe. Fig. 2 represents a through retort of modified form, in which a short ingression pipe is used, and the gas inlet pipe is connected to the same end of the retort as the steam and oil injector. A number of such retorts may be set in a bench, and fired like ordinary coal-gas distilling retorts. It is also proposed to adapt existing coal-gas retorts for carrying out the process, by fitting them with the necessary internal devices and connections.

The body of the retort is filled with deflecting and impact devices D, each composed of an annulus, a disc, a connecting body having numerous narrow longitudinal openings, and inclined spacing or separating legs. These deflectors are made of a shape to correspond with the cross section of the retort, so as to provide uniform passages between them and the walls of the retort. Two or more of the deflectors at the rear end of the retort (where the water gas is supplied) are made with solid discs to act as heaters for the inflowing water gas; but the remainder have their discs provided with central perforations, to receive the ingression pipe or small retort B. This internal retort is preferably made of thin wrought iron, about one-fourth to one-sixth the diameter of the surrounding retort, and long enough to extend from the front to about two-thirds or three-fourths the length of such outer retort—as shown in fig. 1. It is fitted at its front end in an opening in the lid G and is provided with a flange or ring shrunk thereon, which may be bolted to the lid, and is supported centrally as shown. Deflectors made with rings, discs, and legs, and preferably of cast iron, are fitted in the retort B, from its rear open end to near its front end; leaving sufficient space at the front for the proper injection of steam and oil. The injector I is fitted to the retort lid, so as to open centrally into the retort B. The double steam superheating coil C is preferably arranged at or near the front of the retort A, around the retort B; and a steam-supply pipe connects with its induction and through the lid, while another pipe

leads from its outlet end through the lid to the injector I. A supply-pipe for petroleum, shale oil, or other hydrocarbon fluid, also connects with the injector. The steam pipe preferably connects with the front end of the injector, while the oil-pipe connects with its top or side, as shown. A pipe F connects with the back mouthpiece, for supplying hydrogen, natural gas, or water gas. A stand-pipe E, leading to the hydraulic main or seal box, connects with the front mouthpiece. The lid G, steam coil C, and injector I, may be so connected that they may be removed together, without disturbing the ingression pipe or retort B. The deflectors D in the outer retort, may be made of fire clay or other refractory material, though preferably of cast iron.

Vapours and gases—such as steam, oil vapour, and hydrogen gas—cannot be effectually heated, decomposed, and combined by radiation from contiguous hot surfaces, says the patentee; and he has found it necessary to cause the vapours and gases to pass, by direct and repeated impact, in contact with the hot surfaces extending through the area of the retort, in order to effect their uniform and economical decomposition and combination, to form a homogeneous fixed gas. For securing the best results above stated, the deflecting and impact devices are found to admirably answer the purpose; and they are important features in successfully carrying out the process. For some reason, however, which the inventor is unable satisfactorily to explain, cast-iron deflecting devices are more efficient than those made of other material. It would appear, he says, that during the gas-making process, the molecules of the iron deflectors occupy a position of unstable equilibrium, and by acting as a sort of “common carrier,” promote the necessary chemical interchanges.

In the modified form of apparatus represented in fig. 2, the ingression pipe or small internal retort is made short, and arranged to discharge steam and hydrocarbon fluid near the front end of the large retort, in contact with the deflecting and impact devices D. The supply-pipe for admitting a chemically active diluting agent (such as natural gas, hydrogen, or water gas) connects with the front end of the retort, so that the steam, hydrocarbon fluid, and diluting gas are caused to pass together in contact with the deflectors throughout the whole length of the retort. There being only a short ingression pipe, the discs, except the first, are here made solid throughout, and present a larger heating surface than where the ingression pipe passes through them; but, of course, the special advantages of the ingression pipe itself are sacrificed. The gas stand-pipe E connects with the rear mouthpiece.

In order to manufacture gas, the operation is as follows:—The retorts are fired in the ordinary way, and when heated to the proper gas-making temperature, a supply of high-pressure steam from the boiler is admitted through an ordinary regulating valve to the superheating coil C, whence it passes, in a highly superheated state, to the injector I. The hydrocarbon oil is then admitted in regulated quantity from the supply-tank to the injector, from which it is thrown in a vapour spray, by the jet of superheated steam, into the ingression pipe or retort B. The steam and oil vapours are thoroughly mixed and highly heated, nearly to the point of decomposition, by contact with the deflecting and impact devices in their passage through the small retort, and are discharged therefrom into the main retort, where the production of fixed gas at once begins. After gradually admitting oil to the injector, hydrogen—light carburetted hydrogen (such as natural gas or water gas)—is admitted in regulated quantity through the pipe F into the larger retort, where it is heated by contact with the deflectors D. The heated gas meets the highly-heated current of oil-vapour and steam flowing from the retort B, and the mixture flows in contact with the deflecting and impact devices surrounding the retort, or arranged beyond its discharge end, resulting in their complete decomposition and recombination, so as to form “a fixed high-grade illuminating gas.” In this reaction, it is claimed that the hydrogen gas present chemically unites with the rich hydrocarbon vapour or gas in the nascent state, to form fixed carburetted hydrogen gas of a merchantable character, and some of the carbonic oxide and marsh gas enter into new combinations, by which the light-giving quality of the final product is improved. The hydrocarbons are thus utilized and prevented from being destructively decomposed, with the formation of lamp-black or hard carbon on the one hand, or on the other hand, from passing off in the form of tarry condensable vapour.

OPENING, CLOSING, AND SECURING THE GLASS SHADES OR GLOBES OF WENHAM LAMPS, AND LIGHTING AND MANIPULATING THE LAMPS.—Hempel, E. J., of Dresden. No. 12,880; Sept. 6, 1888. [6d.]

The object of this invention is to provide means for opening, closing, and securing the glass shades or globes of the ordinary type of regenerative gas-lamps, and for lighting and otherwise manipulating them. The device for this purpose consists of a rod or handle, fitted with wires, a lighting lamp, and a hook used in combination with a ring, pins, and a set-screw fitted to a locking bar, so as to permit of the opening, closing, and lighting of the lamp at one operation.

THE GROSVENOR GALLERY ELECTRICAL INSTALLATION.

SIR,—On a recent visit to London, when I arrived (about 6 p.m.) at what I thought ought to be the Charing Cross Station of the Metropolitan District Railway, I found I could not read the name of the station on the lamps which gave a very faint glimmer of a reddish hue. I discovered that they were supplied from the Grosvenor Gallery Electric Light Company, and gave so poor a light that it was almost perilous to move about the station. The ticket taker, although he had an incandescent lamp close to him, could not check the tickets by its faint glow, and had to light a gas-lamp before he could read the figures on the tickets. I used my umbrella as a very rough photometer—placing it at about an equal distance from the gas and the electric lights—with the result that, while the shadow of the first was well defined and strong, it was barely possible to see the shadow of the second in the brighter field illumined by the gas-light. I came to the station again at 11 p.m., and found things a shade better; but I should guess that the light given by the 16-candle (?) electric lamp did not average more than 4 candles. The present price charged by the Grosvenor Gallery people is 7½d. per nominal unit, or equal to 6s. 3d. per 1000 cubic feet of gas. Now if the light given was only one-fourth of the nominal power, the cost would be really equal to 25s. per 1000 cubic feet. What would be said of gas companies if they performed their duties in this way?

It is said, in excuse, that the Company have taken on more consumers than they can supply. Again, What would be said of a gas company under contract to give a minimum pressure of 1 inch of water if they gave only 2-10ths? I believe a good many of the consumers have contracted for so much per lamp; and most electricians say that the Ferranti meter is not to be relied on. I trust in justice to the consumer they will make proportionate allowance for supplying only 4 candles, instead of 16. Indeed, as there are men of the highest character on the Board, I am sure they will feel bound to take this course, and not make up a fictitious dividend by any avoidance of their obligations to the public.

I would be glad if you could get some competent person to test the lights at the station I have mentioned, and at other places.

Nov. 28, 1888.

A PROVINCIAL.

MR. ELLIS LEVER AND SALFORD GAS AFFAIRS.

SIR,—I have read in the JOURNAL of Tuesday last, a letter upon this subject from Mr. James Ward. It contains such extraordinary statements, that I think they should be answered.

Mr. Ward commences by stating that he was “one of the young members of the old Gas Committee.” Mr. Ward may have some satisfaction in knowing that the frauds were greatest during the past six or eight years of the Hunter, or shall I say more correctly, Sharp régime—for Mr. Alderman Sharp was the Chairman of the Gas Committee during the whole time that Hunter was the Gas Engineer. These frauds are more gigantic than most folks know. However sincere Mr. Ward may have been to introduce reform, his presence on the Gas Committee did not immediately effect any good to the ratepayers. I do not here wish to champion Mr. Ellis Lever; but I should not be surprised to learn that, if he ever did business with the Salford Corporation, he would be compelled, like many of the other contractors, to submit to blackmail. As to Mr. Lever's relationship with Mr. Hunter, and the alleged offer of the use of a house at Colwyn Bay, &c., Mr. Ward must know that to keep the Engineer or the Gas Committee at arm's length was not the best way to secure a contract. Mr. Ward was himself a great friend of Mr. Hunter; but it does not necessarily follow that the friendship was for any dishonourable motive. Mr. Ward's statements prove the adage “that a little knowledge is a dangerous thing;” for he has forgotten, or has never known, that Mr. Alderman Sharp, who was Chairman of the Gas Committee, in a statement made by him on oath at the trial, *Regina v. Lever*, said he “had made up his mind that, so long as he (Sharp) was on the Gas Committee, Mr. Ellis Lever should never have a contract.” Allow me, also, to tell Mr. Ward that it was not a question of price, nor, as he very naively admits, a question of quality, of coal that guided the Gas Committee in their selection of the contractor.

Let us consider the matter of the contract when the Gas Committee refused Mr. Ellis Lever's offer at 9s. 6d. per ton, and accepted another gentleman's at 8s. 6d. Mr. Ward says: “In no single instance was a tender at 9s. 6d. considered. Why this sophistry, Mr. Ward? You who know so much about gas making and purification! Do you know what became of the tenders before they were submitted to the Gas Committee, or what became of them after? Was there a single tender sent in by any would-be contractors retained in the archives of the Corporation, and obtainable for reference (say) in May, 1887? How many tenders were considered when the final bargain was made in coal by the Gas Committee, which resulted in a saving to the ratepayers of £8000? How many cubic feet of gas per ton was made with the extraordinary coal described three times by Mr. Ward, regarding which it is not necessary to consider the quality, but only to look well to the purifying? Is it not a fact that for years, during the time this extraordinary cheap coal was being used, numerous—almost daily—complaints were made as to the quality of the gas. It is asserted, on the most reliable authority, that the illuminating power rarely, if ever, exceeded 15 candles. Will Mr. Ward tell us how much of this coal was weighed by the Railway Company who carried it, or by the Gas Committee's servants who received it. Further, was the stock of coal taken? During the past twelve months it has been asserted in the Council that they were 30,000 tons short; but it has been admitted, and I believe is a fact, that in the past twelve months there is 3000 tons in some way unaccounted for.

I think if we were to go into facts, Mr. Ward's figures would be easily disposed of; and it would not be difficult to show, as Mr. Lever asserts, a possible loss of £25,000. If Mr. Ward tells us what was the cost of this peculiar system of purification in each year that he was a young member of the old Gas Committee, I will show him that he should never prophecy before he knows. Was Mr. Ward a member of the deputation who visited gas-works in other towns, to seek information as to the

advisability of erecting at the Salford Gas-Works a sulphate plant; and did that deputation take the Gas Engineer to show them, I presume, what a gas-works was like, and then leave him outside? The only part, I believe, the Manager was allowed to take in the proceedings was to partake of the good cheer which the deputation always comforted themselves with.

I am perfectly convinced that if the Gas Committee had done its duty by the ratepayers, none of these frauds would have been perpetrated, and Samuel Hunter would probably have never been in prison. Mr. Ward has not forgotten that the "Investigation Committee," in their report to the Council, said that "the Gas Committee stood discredited and condemned." Mr. Ward was a member of that Committee. If he seeks to defend the transactions of the Committee of which he was only a young member, why does he not take up the cudgels against this condemnation of the Investigation Committee? He may also answer a few of the questions I have put to him, which I venture to submit are as pertinent to the question of the Salford gas mismanagement as any he has propounded.

Forest Hill, S.E., Nov. 29, 1888.

SAMUEL HAYWARD.

THE IRONMONGERS' EXHIBITION.

SIR,—While thanking you for your exhaustive and critical review in this week's JOURNAL of the late Ironmongers' Iron and Metal Trades Exhibition, I would suggest that your remarks as to its scope running so far into the builders' and furniture exhibition are a trifle unjust. On the one hand, the bulk of my exhibition would be mere sections or "hanging on" to the general idea of either of the exhibitions you mention; and, on the other hand, both these exhibitions, which you mention as "annual," have been dropped for some time. Being the first of the kind, some of the larger firms were naturally a trifle shy; but judging from the support I am already receiving for my next show (March, 1890), I think I can safely promise that all your objections will be met then. I can assure you that any suggestions as to the improvement of the show will be gladly acted upon.

Nov. 30, 1888.

HARRY ETHERINGTON.

PROPOSED NEW WATER-WORKS FOR ROSCOMMON.—An inquiry has recently been held at Roscommon, by Mr. R. O'Brien Smyth, one of the Local Government Board Inspectors, into an application to borrow £5000 for the construction of new water-works for the town. There was practically no opposition to the proposal. It is stated that the town has been in a deplorable condition as regards water; and it is intended to make the entire union contribute towards the expense of the scheme.

CROMER GAS COMPANY.—Mr. G. Breeze, presiding at the annual meeting of this Company last week, was able to announce an increase of profits over the preceding twelve months, and sufficient to justify the Board in recommending a dividend at the rate of 5 per cent. per annum, free of income-tax. In view of the cost of the replacement of retorts next year, and also an extension of retort power to meet the increasing consumption, the Directors were desirous to carry forward as large a balance as practicable, and therefore did not suggest a higher dividend.

THE GAS-WORKS AT THE HANWELL SCHOOLS.—Yesterday week the question which has several times of late been agitating the Managers of the Central London District Poor Law Schools at Hanwell—as to the alterations and improvements necessary at their gas-works—was again under discussion (see *ante*, pp. 731, 807). The Farm Committee recommended, and it was agreed to employ Messrs. Alfred Williams and Co., of Bankside, to carry out the work suggested by Mr. W. F. Broadberry. It is anticipated that, if a more suitable class of coal is employed, the cost of gas manufacture will be reduced to 2s. 7d. per 1000 cubic feet—or 5d. per 1000 feet less than the price at which the Brentford Gas Company offer to supply it. A saving will thus be effected of about £83 on such a consumption as that of last year, which was 4,023,670 feet.

THE HOLIDAY QUESTION AT THE BIRMINGHAM GAS-WORKS.—The gas stokers and yard-men from Alderley Street and Swan Village who benefit by the resolution recently passed by the Council, according to a week's holiday during the summer, gave a complimentary breakfast to Mr. Councillor R. Nixon and Messrs. J. R. Oswald, J. Cawley, and R. Benson, last Sunday week. Mr. J. Cawley, Chairman of the Committee, presided; and the Company numbered about 100. After breakfast, the following resolution was passed:—"That the thanks of this meeting be tendered to the Mayor and Corporation of Birmingham for their kindness in conceding a week's holiday to the men engaged in the Gas Department, and that a copy of this resolution be forwarded to the Mayor and Chairman of the Gas Committee." Mr. Nixon, in acknowledging the resolution, expressed regret that an endeavour should have been made to gain party capital out of the circumstances. He had scrupulously avoided any such possibility, because he thought that the introduction of party politics would have been unfair to the men, and might possibly have endangered the success of the agitation. He trusted that everyone would use to good purpose the time given, and so enjoy to the full the concession made. A resolution thanking Messrs. Nixon, Oswald, Cawley, and Benson for their services was also carried unanimously. These gentlemen having suitably replied, the proceedings were brought to a conclusion with a vote of thanks to the Chairman.

THE OIL LIGHTING OF ERITH.—In consideration of Messrs. Defries forgoing their claim for damage which was done to the old gas-lanterns in transit from Erith to Messrs. Defries' works, the Erith Local Board have decided not to enforce the penalties to which the contractors have become liable by the non-lighting of the oil-lamps. This penalty amounts to 2s. 6d. for each lamp not lighted; and the fines already incurred total up to £11 5s. Perhaps, says our correspondent in the district, the Board have a right to be generous with the ratepayers' money, and pay for what they have not received; for as a matter of fact, the question of the damaged lanterns was only a side-wind by which a glaring inconsistency could be blown away. But if they choose to ignore that a "contract is a contract" they have certainly no right to endeavour to palliate their conduct by publicly stating—as several of the members did—that if a record had been kept of the lamps found not lighted when the Gas Company had the contract, the result would not have been satisfactory. There are ninety half-crowns in £11 5s.; and that means that during the brief period this district has been "illuminated" by oil-lamps, ninety lamps have been found unlit. This is a very large number; and if the West Kent Gas Company had been the offenders, there would have been nothing strong enough to hold the members of the Erith Local Board within the bounds of that "dignity" which they talk so much about. They would have collapsed altogether.

Parliamentary Intelligence.

NOTICES GIVEN FOR PRIVATE BILLS (SESSION 1889) RELATING TO THE SUPPLY OF GAS, WATER, AND ELECTRICITY.

BARROW-IN-FURNESS CORPORATION.—This is an application by the Barrow-in-Furness Corporation for leave to introduce a Bill empowering them to construct new water-supply works and to take water from the River Duddon and elsewhere. The notice comprises provisions in regard to the compulsory purchase of lands, the variation and extinguishment of water rights, and the supply of water for domestic and trade purposes. An extension of the time within which the water-works authorized by the Corporation's Act of 1875 may be constructed is desired; and authority is asked to form gas and water reserve funds, and a fund for working capital for gas and water purposes. Clauses in relation to financial and other general matters are included.

BARROW HEMATITE STEEL COMPANY, LIMITED (WATER SUPPLY).—This Company intend making application for leave to introduce a Bill giving them powers to construct water-supply works, purchase lands and water rights, and to divert and use the waters of Crosby Gill and of the River Duddon. They seek authority to apply their existing funds to the purposes of the Bill and to raise additional capital. A provision is inserted in the notice authorizing the transfer to the Corporation of Barrow-in-Furness of the powers conferred by the intended Act and any works constructed thereunder.

BARRY AND CADOXTON GAS AND WATER.—This is an application by the Barry and Cadoxton Gas and Water Company for leave to construct works specified in the notice—including a service reservoir, wells, and pipe-lines. The applicants require permission to purchase lands, waters, and other property, and to lay down, remove, and renew their pipes. Adjustment of the existing capital and further powers in this respect are sought. A provision is to be included in the proposed Bill asking for authority to dispose of the undertakings of the Company to the Local Board; and, upon transfer, to invest this Board with all the powers and privileges of the Company. The Local Board is to be empowered to apply their existing funds, and raise additional money, for the purpose of such purchase. A clause providing, in the case of sale, for the winding up of the affairs of the Company is embraced in the notice.

BELFAST WATER.—Power is intended to be sought by the Belfast Water Commissioners to construct filtering-basins, a reservoir, and incidental works. They also ask for an extension of time for the exercise of compulsory powers to take land, and for the completion of certain works, authorized by the Belfast Water Act of 1884. Provisions are to be inserted in the proposed Bill in regard to new borrowing powers, the conversion of existing mortgages of the Commissioners into stock, and as to granting and charging for plumbers' licenses.

BRISTOL WATER.—Notice is given by the Bristol Water Company that they purpose making application for powers to construct, among other things, a reservoir (to be called the Yeo reservoir), to be formed by means of an embankment across the valley of the River Yeo, and a pumping station; also the necessary water towers, filter-beds, &c. They also wish to be enabled to abandon certain works authorized by the Act of 1888—chiefly the pumping station known as No. 2, and various lines of pipes. Provisions are to be included in the proposed Bill in reference to the breaking up of roads, the laying of pipes, the acquisition of lands, and agreements with mill and mine owners, and public bodies. For the purpose of carrying out the intended works, additional capital is required.

BURNLEY CORPORATION EXTENSION.—Notice is given by the Corporation of Burnley of their intention to apply for leave to introduce a Bill authorizing the extension of the borough boundaries, and the limits within which they have power to supply gas and water. It is sought to repeal and amend all Acts empowering the Padiham Local Board to supply gas and water within the township of Habergham Eaves, and to prohibit the Board continuing to supply gas or water within the township; and sanction is sought to purchase the mains and other works belonging to the Board situated therein. The Corporation wish to be enabled to enlarge their existing gas-works, and to construct additional works both for gas manufacture and the conversion of residual products, upon land which they desire to be authorized to acquire. Permission is required to apply existing funds, and the enlarged borrowing powers asked for, to the purposes of the proposed Bill.

BURY CORPORATION WATER.—The Corporation of Bury give notice that they intend to apply for authority to construct new works for water supply—comprising chiefly a reservoir to be called "Clough Bottom," a catchwater drain or conduit, and an aqueduct. In order to carry out these works, sanction is sought to compulsorily purchase lands, to divert roads and footpaths, and various streams. The owners and occupiers of mills and other works are to be protected; and provision is made with respect to compensation water. The Corporation ask for permission to revise the charges for water supplied by them, and to apply for the purposes of the proposed works their funds, and any moneys which they may now be authorized to raise. It is desired to repeal a portion of sections 129 and 131 of the Bury Improvement Act of 1885 as to sinking funds, and to make other provisions for the repayment of money borrowed by the Corporation in respect of their water undertaking, and the payment off of the annuities created for water-works purposes under the Bury Improvement Act of 1872.

CHELTEMHAM IMPROVEMENT.—In the notice of an application to be made for general powers, the Cheltenham Corporation have a clause to authorize trustees or other persons holding annuities under the Cheltenham Corporation Water Act of 1878 to invest the proceeds thereof, on purchase or redemption, in the purchase of Cheltenham Corporation Stock.

CLEVELAND WATER.—The Cleveland Water Company intend to ask for leave to alter and vary the existing rates, rents, and charges, and for power to increase them, and in particular to fix or prescribe the minimum rents or charges at which they shall be bound to supply water to houses or other premises.

COVENTRY CORPORATION WATER.—The Corporation of Coventry seek authority to maintain their existing water-works, and to construct additional works—comprising two wells and pumping stations, two service reservoirs, the necessary pipe-lines, &c. Power is sought to take and impound water, and to purchase, by compulsion or agreement, lands and other property. Extension of limits within which water may be supplied is desired; and also powers regarding rates and charges, misuse and pollution of water, agreements with local authorities, &c. For the above objects further borrowing powers are asked.

DEANHEAD WATER.—The Commissioners of the Deanhead reservoir purpose applying for authority to use and maintain their existing Deanhead reservoir and works situated on the Blackbourne Brook, in the parish of

advisability of erecting at the Salford Gas-Works a sulphate plant; and did that deputation take the Gas Engineer to show them, I presume, what a gas-works was like, and then leave him outside? The only part, I believe, the Manager was allowed to take in the proceedings was to partake of the good cheer which the deputation always comforted themselves with.

I am perfectly convinced that if the Gas Committee had done its duty by the ratepayers, none of these frauds would have been perpetrated, and Samuel Hunter would probably have never been in prison. Mr. Ward has not forgotten that the "Investigation Committee," in their report to the Council, said that "the Gas Committee stood discredited and condemned." Mr. Ward was a member of that Committee. If he seeks to defend the transactions of the Committee of which he was only a young member, why does he not take up the cudgels against this condemnation of the Investigation Committee? He may also answer a few of the questions I have put to him, which I venture to submit are as pertinent to the question of the Salford gas mismanagement as any he has propounded.

Forest Hill, S.E., Nov. 29, 1888.

SAMUEL HAYWARD.

THE IRONMONGERS' EXHIBITION.

SIR,—While thanking you for your exhaustive and critical review in this week's JOURNAL of the late Ironmongers' Iron and Metal Trades Exhibition, I would suggest that your remarks as to its scope running so far into the builders' and furniture exhibition are a trifle unjust. On the one hand, the bulk of my exhibition would be mere sections or "hanging on" to the general idea of either of the exhibitions you mention; and, on the other hand, both these exhibitions, which you mention as "annual," have been dropped for some time. Being the first of the kind, some of the larger firms were naturally a trifle shy; but judging from the support I am already receiving for my next show (March, 1890), I think I can safely promise that all your objections will be met then. I can assure you that any suggestions as to the improvement of the show will be gladly acted upon.

Nov. 30, 1888.

HARRY ETHERINGTON.

PROPOSED NEW WATER-WORKS FOR ROSCOMMON.—An inquiry has recently been held at Roscommon, by Mr. R. O'Brien Smyth, one of the Local Government Board Inspectors, into an application to borrow £5000 for the construction of new water-works for the town. There was practically no opposition to the proposal. It is stated that the town has been in a deplorable condition as regards water; and it is intended to make the entire union contribute towards the expense of the scheme.

CROMER GAS COMPANY.—Mr. G. Breeze, presiding at the annual meeting of this Company last week, was able to announce an increase of profits over the preceding twelve months, and sufficient to justify the Board in recommending a dividend at the rate of 5 per cent. per annum, free of income-tax. In view of the cost of the replacement of retorts next year, and also an extension of retort power to meet the increasing consumption, the Directors were desirous to carry forward as large a balance as practicable, and therefore did not suggest a higher dividend.

THE GAS-WORKS AT THE HANWELL SCHOOLS.—Yesterday week the question which has several times of late been agitating the Managers of the Central London District Poor Law Schools at Hanwell—as to the alterations and improvements necessary at their gas-works—was again under discussion (see *ante*, pp. 731, 807). The Farm Committee recommended, and it was agreed to employ Messrs. Alfred Williams and Co., of Bankside, to carry out the work suggested by Mr. W. F. Broadberry. It is anticipated that, if a more suitable class of coal is employed, the cost of gas manufacture will be reduced to 2s. 7d. per 1000 cubic feet—or 5d. per 1000 feet less than the price at which the Brentford Gas Company offer to supply it. A saving will thus be effected of about £83 on such a consumption as that of last year, which was 4,023,670 feet.

THE HOLIDAY QUESTION AT THE BIRMINGHAM GAS-WORKS.—The gas stokers and yard-men from Alderley Street and Swan Village who benefit by the resolution recently passed by the Council, according them a week's holiday during the summer, gave a complimentary breakfast to Mr. Councillor R. Nixon and Messrs. J. R. Oswald, J. Cawley, and R. Benson, last Sunday week. Mr. J. Cawley, Chairman of the Committee, presided; and the Company numbered about 100. After breakfast, the following resolution was passed:—"That the thanks of this meeting be tendered to the Mayor and Corporation of Birmingham for their kindness in conceding a week's holiday to the men engaged in the Gas Department, and that a copy of this resolution be forwarded to the Mayor and Chairman of the Gas Committee." Mr. Nixon, in acknowledging the resolution, expressed regret that an endeavour should have been made to gain party capital out of the circumstances. He had scrupulously avoided any such possibility, because he thought that the introduction of party politics would have been unfair to the men, and might possibly have endangered the success of the agitation. He trusted that everyone would use to good purpose the time given, and so enjoy to the full the concession made. A resolution thanking Messrs. Nixon, Oswald, Cawley, and Benson for their services was also carried unanimously. Those gentlemen having suitably replied, the proceedings were brought to a conclusion with a vote of thanks to the Chairman.

THE OIL LIGHTING OF ERITH.—In consideration of Messrs. Defries forgoing their claim for damage which was done to the old gas-lanterns in transit from Erith to Messrs. Defries' works, the Erith Local Board have decided not to enforce the penalties to which the contractors have become liable by the non-lighting of the oil-lamps. This penalty amounts to 2s. 6d. for each lamp not lighted; and the fines already incurred total up to £11 5s. Perhaps, says our correspondent in the district, the Board have a right to be generous with the ratepayers' money, and pay for what they have not received; for as a matter of fact, the question of the damaged lanterns was only a side-wind by which a glaring inconsistency could be blown away. But if they choose to ignore that a "contract is a contract" they have certainly no right to endeavour to palliate their conduct by publicly stating—as several of the members did—that if a record had been kept of the lamps found not lighted when the Gas Company had the contract, the result would not have been satisfactory. There are ninety half-crowns in £11 5s.; and that means that during the brief period this district has been "illuminated" by oil-lamps, ninety lamps have been found unlit. This is a very large number; and if the West Kent Gas Company had been the offenders, there would have been nothing strong enough to hold the members of the Erith Local Board within the bounds of that "dignity" which they talk so much about. They would have collapsed altogether.

Parliamentary Intelligence.

NOTICES GIVEN FOR PRIVATE BILLS (SESSION 1889) RELATING TO THE SUPPLY OF GAS, WATER, AND ELECTRICITY.

BARROW-IN-FURNESS CORPORATION.—This is an application by the Barrow-in-Furness Corporation for leave to introduce a Bill empowering them to construct new water-supply works and to take water from the River Duddon and elsewhere. The notice comprises provisions in regard to the compulsory purchase of lands, the variation and extinguishment of water rights, and the supply of water for domestic and trade purposes. An extension of the time within which the water-works authorized by the Corporation's Act of 1875 may be constructed is desired; and authority is asked to form gas and water reserve funds, and a fund for working capital for gas and water purposes. Clauses in relation to financial and other general matters are included.

BARROW HEMATITE STEEL COMPANY, LIMITED (WATER SUPPLY).—This Company intend making application for leave to introduce a Bill giving them powers to construct water-supply works, purchase lands and water rights, and to divert and use the waters of Crosby Gill and of the River Duddon. They seek authority to apply their existing funds to the purposes of the Bill and to raise additional capital. A provision is inserted in the notice authorizing the transfer to the Corporation of Barrow-in-Furness of the powers conferred by the intended Act and any works constructed thereunder.

BARRY AND CADOXTON GAS AND WATER.—This is an application by the Barry and Cadoxton Gas and Water Company for leave to construct works specified in the notice—including a service reservoir, wells, and pipe-lines. The applicants require permission to purchase lands, waters, and other property, and to lay down, remove, and renew their pipes. Adjustment of the existing capital and further powers in this respect are sought. A provision is to be included in the proposed Bill asking for authority to dispose of the undertakings of the Company to the Local Board; and, upon transfer, to invest this Board with all the powers and privileges of the Company. The Local Board is to be empowered to apply their existing funds, and raise additional money, for the purpose of such purchase. A clause providing, in the case of sale, for the winding up of the affairs of the Company is embraced in the notice.

BELFAST WATER.—Power is intended to be sought by the Belfast Water Commissioners to construct filtering-basins, a reservoir, and incidental works. They also ask for an extension of time for the exercise of compulsory powers to take land, and for the completion of certain works, authorized by the Belfast Water Act of 1884. Provisions are to be inserted in the proposed Bill in regard to new borrowing powers, the conversion of existing mortgages of the Commissioners into stock, and as to granting and charging for plumbers' licenses.

BRISTOL WATER.—Notice is given by the Bristol Water Company that they purpose making application for powers to construct, among other things, a reservoir (to be called the Yeo reservoir), to be formed by means of an embankment across the valley of the River Yeo, and a pumping station; also the necessary water towers, filter-beds, &c. They also wish to be enabled to abandon certain works authorized by the Act of 1888—chiefly the pumping station known as No. 2, and various lines of pipes. Provisions are to be included in the proposed Bill in reference to the breaking up of roads, the laying of pipes, the acquisition of lands, and agreements with mill and mine owners, and public bodies. For the purpose of carrying out the intended works, additional capital is required.

BURNLEY CORPORATION EXTENSION.—Notice is given by the Corporation of Burnley of their intention to apply for leave to introduce a Bill authorizing the extension of the borough boundaries, and the limits within which they have power to supply gas and water. It is sought to repeal and amend all Acts empowering the Padiham Local Board to supply gas and water within the township of Habergham Eaves, and to prohibit the Board continuing to supply gas or water within the township; and sanction is sought to purchase the mains and other works belonging to the Board situated therein. The Corporation wish to be enabled to enlarge their existing gas-works, and to construct additional works both for gas manufacture and the conversion of residual products, upon land which they desire to be authorized to acquire. Permission is required to apply existing funds, and the enlarged borrowing powers asked for, to the purposes of the proposed Bill.

BURY CORPORATION WATER.—The Corporation of Bury give notice that they intend to apply for authority to construct new works for water supply—comprising chiefly a reservoir to be called "Clough Bottom," a catchwater drain or conduit, and an aqueduct. In order to carry out these works, sanction is sought to compulsorily purchase lands, to divert roads and footpaths, and various streams. The owners and occupiers of mills and other works are to be protected; and provision is made with respect to compensation water. The Corporation ask for permission to revise the charges for water supplied by them, and to apply for the purposes of the proposed works their funds, and any moneys which they may now be authorized to raise. It is desired to repeal a portion of sections 129 and 131 of the Bury Improvement Act of 1885 as to sinking funds, and to make other provisions for the repayment of money borrowed by the Corporation in respect of their water undertaking, and the payment off of the annuities created for water-works purposes under the Bury Improvement Act of 1872.

CHELTEMHAM IMPROVEMENT.—In the notice of an application to be made for general powers, the Cheltenham Corporation have a clause to authorize trustees or other persons holding annuities under the Cheltenham Corporation Water Act of 1878 to invest the proceeds thereof, on purchase or redemption, in the purchase of Cheltenham Corporation Stock.

CLEVELAND WATER.—The Cleveland Water Company intend to ask for leave to alter and vary the existing rates, rents, and charges, and for power to increase them, and in particular to fix or prescribe the minimum rents or charges at which they shall be bound to supply water to houses or other premises.

COVENTRY CORPORATION WATER.—The Corporation of Coventry seek authority to maintain their existing water-works, and to construct additional works—comprising two wells and pumping stations, two service reservoirs, the necessary pipe-lines, &c. Power is sought to take and impound water, and to purchase, by compulsion or agreement, lands and other property. Extension of limits within which water may be supplied is desired; and also powers regarding rates and charges, misuse and pollution of water, agreements with local authorities, &c. For the above objects further borrowing powers are asked.

DEANHEAD WATER.—The Commissioners of the Deanhead reservoir purpose applying for authority to use and maintain their existing Deanhead reservoir and works situated on the Blackburne Brook, in the parish of

Huddersfield, to construct additional works, and to divert and impound certain waters for the proposed new works. Provisions are inserted in the notice in regard to compensation water, breaking up of roads, compulsory purchase of land, &c., and permission is sought to supply water by agreement or otherwise in the townships of Stainland with Old Lindley and Barkisland, to make contracts for the supply of water in bulk to local authorities, and to borrow further money upon the credit of the income receivable from the sale of water.

EASTBOURNE WATER.—The Eastbourne Water-Works Company intend to seek authority to construct certain new works, to alter existing works, and to have the period limited by their Act of 1881 extended for the completion of reservoirs named in the present notice. Further share and loan capital are needed for the objects of the proposed Bill and the general purposes of the undertaking.

EAST KENT DISTRICT WATER.—It is proposed to apply for powers to incorporate a Company for the supply of water to Sandwich, Ash, Eastry, St. Margaret's-at-Cliffe, and other places in Kent. For this purpose authority to construct works at East Langdon, to acquire lands, waters, &c., and to lay pipes, is required. Power is desired to levy rates, to supply water in bulk, and to make agreements with any sanitary authority and other body for the sale of the concern.

EDINBURGH AND DISTRICT WATER.—The Edinburgh and District Water Trustees announce their intention of applying for power to borrow additional money to enable them to complete works already authorized, including works for the more effective filtration and distribution of the water supplied by them. They also wish to be authorized to alter or cancel existing agreements, and to enter into others in regard to the supply of water to local bodies.

FAVERSHAM GAS.—The Faversham Gas Company, Limited, notify their intention to apply for power to dissolve the Company, annul the Memorandum and Articles of Association, and to re-incorporate the shareholders into a Company of the name of the "Faversham Gas Company," in which will be vested the existing works, &c. Provisions are to be included in the proposed Bill, in regard to the conduct of the Company's affairs, the arrangement of capital, the conversion of existing share capital into stock, additional capital, and borrowing powers. Authority is asked to maintain and enlarge the works, and to supply gas in Faversham and certain parishes and townships named in Kent. The applicants desire sanction to construct new works, to manufacture and store gas, and to manufacture and convert residual products on lands described in the notice. Clauses are to be inserted as to the acquirement and disposal of land, the acquisition of patent rights, the breaking up of roads, the making of agreements with public bodies, and other minor matters.

GARW WATER.—It is proposed to make application for leave to incorporate a Company, and to authorize them to supply water to Bettws, Cwmdn, Llangeinor, and a number of other places mentioned in Glamorganshire. Power is sought to maintain the existing, and to construct additional works, to take lands, springs, and streams, and to levy rates. The Bill will amend as much of the Bridgend Gas and Water Act, 1869, as empowers the Bridgend Gas and Water Company to supply water in any of the districts defined in the notice. Permission is asked to acquire the Porthcawl Water-Works, and also the undertaking of the Garw Water and Light Company, or to dissolve and re-incorporate the last-named Company, with further powers. Special provisions are to be included for preventing pollution of streams, &c.

GREAT WIGSTON GAS.—The Great Wigston Gaslight and Coke Company, Limited, intend to apply for powers of dissolution and re-incorporation without limitation, but with the capital of the undertaking rearranged and increased. Authority is sought to continue, maintain, and extend the existing gas-works, manufacture gas therein, and supply it within an area to be defined. The usual powers to make agreements with local authorities and others, to levy rates and charges, and to manufacture and supply stoves and fittings are included in the notice.

HEYWOOD CORPORATION.—Application is proposed to be made by the Heywood Corporation for an extension of the time limited by the Heywood Water Act, 1877, for the construction and completion of the reservoir on Ashworth Moor and other works connected therewith, and for the power to purchase at the end of such period, and upon such terms and conditions as may be mentioned in the intended Act, the annuities issued by them in respect to the purchase of their gas and water undertakings, or otherwise to provide for the determination of such annuities. Provisions as to issuing licenses to plumbers and to prohibit unlicensed persons from executing any work connected with the Corporation water mains and pipes are included in the notice; and further powers in respect to borrowing money for the purposes of the water undertaking are sought.

HUDDERSFIELD CORPORATION WATER.—This is an application by the Huddersfield Corporation, who desire to have transferred, by agreement or compulsorily, and vested in them, the undertaking and property of the Commissioners of the Wessenden Reservoir. The applicants wish to be empowered to make agreements with the Commissioners; and to have the property intended to be transferred to them constituted a part of their water undertaking. Authorization to use existing funds, enlarge present borrowing powers, and raise additional money is required.

HYTHE CORPORATION WATER.—The Corporation of Hythe purpose seeking authority to impound and use for the general purposes of their water-works undertaking the waters of the Black Rook Spring, and to purchase land adjacent thereto. Enlarged borrowing powers are sought for the foregoing and other purposes.

KETTERING WATER.—The Kettering Water Company, Limited, propose making application for power to enable them to dissolve and re-incorporate the proprietors in a Company without limitation, in which Company all the works, &c., will be vested. Further money powers are sought, and also authority to construct additional works, and to purchase lands. Clauses are included in the notice in reference to the rates and charges to be levied by the Company, the supply of water by meter, and the making of agreements with sanitary and other authorities.

LIVERPOOL CORPORATION WATER.—The Liverpool Corporation have given notice of their intention to make application for various general powers, which include a provision to confer upon them authority in respect to the prevention of waste, misuse and fouling of water, and the registration of plumbers and others.

LONDON HYDRAULIC POWER COMPANY.—This Company intend to apply for power so raise further capital, and to alter some of the provisions of the Wharves and Warehouses Steam Power and Hydraulic Pressure Company's Act, 1871, and of the London Hydraulic Power Act, 1884, or of any other Act relating to the Company.

LONG EATON AND DISTRICT WATER.—This is an application for leave to incorporate a Company to supply water in the parishes and townships of Long Eaton, Sandiacre, and Stapleford, in Derbyshire and Nottingham; and for this purpose authority is asked to construct works. The powers necessary for a Water Company to carry on business are sought.

MANCHESTER CORPORATION WATER.—Application is intended to be made by the Manchester Corporation for power to make certain deviations and alterations (fully set forth in the notice) in the line and levels of the aqueduct from Lake Thirlmere to Prestwich authorized by their Water Act of 1879, and to make amendments in the provisions of that Act as to roads and sinking funds. Authorization is also sought to maintain and use two lines of pipes in the county of Chester.

METROPOLIS LOCAL MANAGEMENT.—The Metropolitan Board of Works give notice of their intention to apply for leave to bring in a Bill (in order that the London County Council may be enabled to proceed with the measure if they should so resolve) to confer upon them, *inter alia*, powers "to control and regulate the laying . . . of mains and pipes for water or gas, or hydraulic power purposes, and to remove or limit the liability of vestries and district boards for damage or injury to such mains and pipes."

METROPOLITAN ELECTRIC SUPPLY.—Authority is sought by the Metropolitan Electric Supply Company, Limited, to produce and supply electricity within the parishes of St. James, Westminster, and St. Martins-in-the-Fields, Waterloo Bridge, and the Victoria Embankment. The Company seek to be empowered to break open streets, and to interfere with sewers, pipes, &c., to enter houses and premises supplied by them for any purpose relative to the supply, to levy rates and charges, to make contracts with local authorities, and to apply their funds for these purposes.

MORLEY GAS.—This is a proposal by the Morley Gas Company to apply for powers to acquire additional lands for the purposes of their undertaking, to raise further capital, and to make agreements with public bodies as to the supply of gas.

NEWCASTLE AND GATESHEAD WATER.—Notice is given by the Newcastle and Gateshead Water Company of their intention to apply for permission to construct additional works—embracing a reservoir, a relieving tank, and various pipe-lines or conduits. Powers are asked to break up roads, lay pipes, purchase lands, houses, mines, &c., to make agreements with land, mine, and mill owners, and to give compensation, in money or water, as the circumstances may require, to any person or body injuriously affected by the proposed Bill. Increased share and loan capital is required.

NEWRY IMPROVEMENT.—The Town Commissioners of Newry purpose making application for power, among other things, to amend or repeal all or some of the provisions contained in the Newry Improvement and Water Act, 1871, and in the Newry Commissioners' Gas Act, 1878, relating to the borrowing and repayment of money, and to authorize them to re-borrow the money repaid under these Acts, and to repay all or some of their existing mortgages, and to make further provisions in relation to these matters.

PADIHAM AND HAPTON LOCAL BOARD.—It is proposed by this Board to apply for an Act to extend the boundaries of their district. They also desire authority to construct a compensation reservoir and other works connected with the water supply, to acquire certain lands, and to use their existing funds and any moneys they may now be authorized to raise for these purposes.

PLYMOUTH DOCK (DEVONPORT) WATER.—It is proposed by the Plymouth Dock Water-Works Company to obtain authority to construct various works specified in the notice, to obtain additional land, to extend the limits of supply, to change the name of the Company, to make agreements with the Secretary of State for the War Department, the Lords of the Admiralty, and public bodies, and, in order to carry out their proposals, to increase the share and loan capital.

RASTRICK WATER.—It is intended to make application for the dissolution of the Rastrick Water Company, Limited, and the incorporation of the shareholders into a new Company, with additional borrowing powers. Authority is asked to maintain the existing works, and to construct a new reservoir and other works; and leave is desired to compulsorily purchase lands. Confirmation of an agreement with the Halifax Corporation to supply water in bulk to the Limited Company is sought; and the applicants ask that so much of section 9 of the Halifax Water and Improvement Act of 1868 as authorizes the Corporation to supply water in Rastrick may be repealed.

RICKMANSWORTH AND UXBRIDGE VALLEY WATER.—The Rickmansworth and Uxbridge Valley Water Company announce their intention to apply for power to alter and extend the limits of the area of supply, so as to include Harmondsworth, Sunbury, Shepperton, and Littleton. Authority is asked to construct new works, and to enter into agreements for the supply of water in bulk to water companies and other bodies. The usual provisions as to the application to these purposes of the existing funds and of the additional capital to be raised will be included in the suggested Bill.

SCARBOROUGH IMPROVEMENT.—The Scarborough Corporation purpose applying for a number of general powers to be conferred upon them, among which is authority to make better provision in regard to the supply of water for domestic and other purposes, and to arrange for the redemption of the water annuities.

SOUTH KENT WATER.—This is an application for the incorporation of a Company to supply water to Mereworth, Wrotham, and a number of other small places in Kent. Sanction is sought to construct the necessary works, acquire lands, levy rates and charges, and make agreements with local authorities both as to the supply of water and the sale of the undertaking.

SWANSEA CORPORATION WATER.—In the notice of an application to be made by them for general powers, the Swansea Corporation announce their intention of asking for an extension of the time granted by their Water Act of 1884 for the purchase of land and for the construction and completion of the Upper Liliw Reservoir and other works.

TUNBRIDGE WELLS WATER.—The Tunbridge Wells Improvement Commissioners give notice of a Bill to confer on them, among other things, additional powers in regard to the water-works, to enable them to make further provision as to the rents and charges for the supply of water for domestic and other purposes and by meter, to prevent waste, misuse, and fouling of water, to remove pipes and fittings, and to recover rates and charges by distress.

TUSCAN GAS COMPANY, LIMITED.—This Company intend to apply for an Act to extend, alter, and amend their Memorandum of Association, and to change the title of the Company.

WAKEFIELD CORPORATION WATER.—It is proposed by the Wakefield Corporation to seek for an extension of the time limited by the Wakefield Corporation Water-Works Act, 1880, for the construction and completion of certain works—including, among other things, four reservoirs. They also wish to be empowered to purchase compulsorily or by agreement, lands, mills, and other property for the purpose of their intended works; and to be authorized to borrow money for the execution of these works.

WEST HAM GAS.—The West Ham Gas Company intend to apply for power to raise additional capital, enlarge and extend their borrowing powers, adopt the sliding scale, and deal in meters, stoves, engines, and other appliances incidental to the use of gas. They wish to have the

illuminating power of their gas, as well as the burner apparatus with which it is to be tested, and the testing-places, prescribed. An important clause in the notice is the application for an extension of the provisions of the City of London Gas Act, 1868, with respect to amalgamations, so as to enable the Company, subject to the conditions and regulations prescribed by that Act, to amalgamate with any other Company supplying gas in the Metropolis, or in any district adjoining that of the Company. The auction clauses are asked for in respect of the new capital, which is to be raised on debentures. The Company seek to be enabled, where the powers to borrow for the purposes of capital on the security of their undertaking, or to create an insurance, reserve, or any other fund are limited to a definite proportion of the paid-up share capital, to reckon the premiums invested in the undertaking from every source, as part of the paid-up share capital, and to regulate the amount of such borrowed money or funds accordingly; also, when a reserve fund is provided by the shareholders, at their own expense, out of moneys they might otherwise distribute as dividend, to regulate the amount, investment, and entire appropriation of such fund as they think fit.

WIGAN EXTENSION.—The Corporation of Wigan notify their intention of making application for an extension of the borough boundaries, and to provide for the government of the extended borough by means of District Committees, who will manage the gas and water undertakings of the Corporation and the water undertakings of the Ince, Hindley, and Pemberton Local Boards, which bodies it is proposed to dissolve. Provision is also intended to be made for the debts and liabilities of each such undertaking to be charged upon and the receipts carried to the credit of the respective district. The Corporation further seek to acquire the gas undertaking of the Hindley Local Board. Powers in regard to the issue of Corporation stock and other financial arrangements are sought.

WINDERMERE DISTRICT GAS AND WATER.—This is an application by the Windermere District Gas and Water Company for authority to issue and apply for the purposes of the water undertaking the present unissued capital authorized to be raised under their Act of 1869 without the consent of the shareholders, as provided by section 10 of the Act; and for this purpose to amend the section. Additional borrowing powers are asked for; and also sanction to construct new works connected with the water supply. Provisions are included in the notice referring to compensation water, the levying of rates, &c. The Company also desire to be enabled to supply water for other than domestic purposes without the permission of the owners or occupiers of mills or manufacturing works using the waters of Dubbs Beck.

WOODHALL SPA COMPANY.—It is proposed to ask for power to incorporate a Company bearing this title, to take and maintain the water-works situated in Lindley—viz., a reservoir and pumping station in a field belonging to the Right Hon. Earl Fortescue, a service reservoir, and the line of pipes, aqueduct, and other works connected therewith. They seek for authority to divert and appropriate all streams and waters that may be found on land which belongs to, or may be acquired by them, and to make regulations for the prevention or misuse or contamination of water. The applicants also desire to be invested with power to purchase certain lands in the parish of Woodhall or Kirkstead, to be used as works for the manufacture of gas and residual products; and sanction is asked to the supply of gas and water by them in Woodhall, Kirkstead, Langton, Kirkby-on-Bain, Thornton, Roughton, and Martin. Compulsory powers of purchase of lands and waters are sought; and also authority to levy rates and charges, to acquire and maintain sewers and works belonging to the Woodhall Spa Estate, and to make agreements with the proprietors of the latter.

YEADON WATER.—The Yeadon Water Company intend to seek for powers to construct a new reservoir and other works; and for this purpose to take certain lands. The extension of the present limits of supply is desired, and also authority to alter the existing rates and charges. Provisions relative to agreements with local authorities, the fouling of water, &c., are included in the notice. To the foregoing objects the Company wish to apply existing funds, any moneys which they still have power to raise, and any additional capital they may be allowed.

NOTICES OF APPLICATIONS TO THE BOARD OF TRADE (SESSION 1889), UNDER THE GAS AND WATER WORKS FACILITIES ACT, 1870.

BRIGHTLINGSEA WATER.—Application is proposed to be made by the Brightlingsea Water Company for power to maintain, enlarge, and continue the existing water-works, and to impound therein springs or streams near the site thereof; and also to construct further works. Sanction is required to levy rates for water, and permission to take steps to prevent the pollution and misuse of the Company's water. The applicants desire the capital and borrowing powers to be defined and regulated; and to be permitted to effect contracts for the supply of water in bulk.

BUCKLEY GAS.—Application is to be made for an Order to authorize the undertakers to be named therein, or a Company formed for the purpose, to construct and maintain gas-works, and to supply gas in Buckley and the neighbourhood. All the powers necessary to the carrying on of the business of a Gas Company are sought for.

CORSHAM WATER.—The Corsham Water Company announce their intention of applying for authority to continue and maintain existing water-works, and to supply water within the parishes of Corsham, Pewsham, and Lacock. They also wish to be empowered to construct additional works, and to therein impound the underground waters of certain springs situated in the parish of Pewsham. Sanction is asked to supply water by motor, to make and sell motors, and to let motors on hire; and, further, to make arrangements for the supply of water in bulk or otherwise to local authorities. Permission is also sought to sell absolutely or to lease for a term of years, any part of the undertaking.

FAVERSHAM WATER.—Application is to be made by the Faversham Water Company for authority to maintain and continue water-works and supply water in so much of the parishes of Faversham, Preston, Davington, Ospringe, and other places in Kent, as lie within a radius of a mile and a half from the Faversham Town Hall. Further money powers are sought, as well as authority to make agreements with local bodies for the supply of water in bulk.

HARPENDEN WATER.—It is intended to apply for power to enable the undertakers to be named in the proposed Order to maintain and construct water-works, and to supply water in the parish of Harpenden. Provisions in reference to water-rates, the manufacture, purchase, and sale of meters, and contracts with local authorities are embraced in the notice. It is desired that the capital in respect of the existing works should be determined; and sanction to raise further money is asked.

LLANDRINDOD WELLS WATER.—This is an application by the Llandrindod Wells Water Company for powers to raise additional capital for the purposes of their undertaking.

MARKET RASEN GAS.—The Market Rasen New Lighting Company, Limited, seek to obtain authority to maintain and continue their existing works and plant, and to make such extensions as may, from time to time, be necessary. They also desire power to sell gas in bulk to any local authority authorized to supply gas, or to any gas company, for re-sale in adjoining districts, and to be enabled to acquire patent rights and licenses in relation to the manufacture and distribution of gas. For the various purposes of the proposed Order, additional capital is desired.

MARLOW WATER.—Application is intended to be made by the Great Marlow Water Company, Limited, for authority to maintain and continue their existing works, and to construct such works as may be deemed necessary for the purposes of the Order. They wish to be empowered to supply water in the parishes of Great Marlow, Little Marlow, Woburn, and Medmenham (Bucks), and Bisham and Hurley (Berks); and to have their capital fixed and defined.

MELTON MOWBRAY GAS.—The Melton Mowbray Gas Company, Limited, purpose applying for authority to maintain and continue their existing gas-works, and to manufacture and supply gas within the parishes of Melton Mowbray and Thorpe Arnold, in the county of Leicester, for which, and for the general purposes of the undertaking, additional capital is required. The usual powers as to supplying gas meters, fittings, stoves, &c., levying rates and charges, and making agreements with local authorities are sought.

OTLEY GAS.—Authority is intended to be sought by the Otley Gas Company for authorization to maintain, alter, and re-erect their works; and to supply gas to Otley, Newall-with-Clifton, Farnley, and Weston. Permission is asked to the supply of gas in bulk, and to the extension of the Company's mains. The notice includes the usual powers as to breaking up of streets, purchase of patent rights, &c. To enable the Company to carry out their proposals, additional capital is required.

POCKLINGTON WATER.—The Pocklington Water Company, Limited, notify that they intend applying for power to construct new works; and they ask for sanction to purchase lands for this purpose.

ROMFORD GAS.—The Romford Gas Company propose to ask for power to maintain or discontinue their existing works, and to erect new works for the manufacture, storage, and supply of gas, coke, and residual products. Sanction is required by the Company to acquire and hold patent rights and licenses in relation to the manufacture and distribution of gas and the utilization of residual products. They also desire to be empowered to purchase lands, to make contracts with local authorities, to raise additional capital, and to manufacture, purchase or hire, and supply gas-meters, fittings, and stoves.

ST. IVES (HUNTS) GAS.—The St. Ives (Hunts) Gas Company, Limited, intend seeking authority to maintain and enlarge their existing works, to manufacture gas and residual products, to supply gas subject to the provisions of the Gas-Works Clauses Acts of 1847 and 1871, and to exercise all powers, rights, and privileges as are necessary for, and incidental to a Gas Company. They ask that the existing capital may be defined, and authority given them to raise further capital.

WARMINSTER GAS.—It is proposed by the Warminster Gas and Coke Company to apply for an Order to authorize them to continue and from time to time repair, improve, and enlarge their existing works. Power is asked to supply gas in the parishes of Warminster and Bishopstrow, and to manufacture coal tar, coke, pitch, asphaltum, ammoniacal liquor, oil, and other residual products. Additional lands are required, and also increased borrowing powers. The notice includes provisions relative to the supply of gas in bulk, extension of mains, acquisition of patent rights, rates and charges, &c.

NOTICES TO THE BOARD OF TRADE UNDER THE ELECTRIC LIGHTING ACTS, 1882 AND 1888.

BIRMINGHAM ELECTRIC LIGHT AND POWER.—Application is intended to be made by Messrs. A. Chamberlain and G. Hookham for powers to produce and distribute electricity for public and private purposes within an area (defined in the notice) in the borough of Birmingham; and for this purpose they desire authority to break up streets, acquire land, fix wires, and supply lamps, meters, and fittings. Provisions as to making agreements with the Local Authority, the Postmaster-General, and others are embraced in the notice.

BRIGHTON AND HOVE ELECTRIC LIGHTING.—It is proposed by the Brighton Electric Light Company to ask for sanction to produce and supply electricity for public and private purposes "in all the streets and thoroughfares in the borough of Brighton and parish of Preston, and the town of Hove," including a number of private streets specified in the notice. All the powers necessary for the undertakers to conduct such business are sought.

CHELSEA ELECTRICITY SUPPLY COMPANY.—This Company have given notice of their intention to apply for two Orders to supply electricity (1) in the parish of St. George, Haover Square, and (2) in the parish of Kensington. The applicants ask for authority to construct the necessary works, lay wires, break open streets, acquire land, levy rates, and make agreements with local authorities.

DUBLIN ELECTRIC LIGHTING.—The Corporation of Dublin give notice of their intention to apply for authority to supply electricity for all public and private purposes within the city, and for this purpose to erect and maintain works and lines, and exercise all the necessary powers incidental to the business. The streets in which lines are first to be placed are specified in the notice; and the applicants do not propose to ask for power to break up any streets not under the control of the Local Authority.

ELECTRICAL POWER STORAGE COMPANY.—This Company intend to apply for two Orders, authorizing them to produce and supply electricity in (1) Paddington, and (2) St. Martin's-in-the-Fields and the Strand district. They ask for powers to enable them to construct works and to make all arrangements necessary to the carrying out of their proposals.

KENSINGTON ELECTRIC LIGHTING.—The House-to-House Electric Light Supply Company, Limited, purpose making application for power to supply electricity in the parish of St. Mary Abbots, Kensington; certain streets and places (specified in the notice) being excepted. Authority is sought to make charges, acquire land, construct works, make arrangements with local authorities, and to open streets.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING.—Authority is sought by the Kensington and Knightsbridge Electric Lighting Company, Limited, to supply electricity for public and private purposes in the parishes of St. Mary Abbots, Kensington, and St. Margaret, Westminster, for which object they require power to construct the necessary works, acquire lands, break up and interfere with streets, and make arrangements with local authorities.

LIVERPOOL ELECTRIC LIGHTING.—The Liverpool Electric Supply Company, Limited, propose to apply for power to produce and supply electricity for lighting and other purposes in the city. They wish for authority to break up streets and roads, and lay down wires, as well as for constructing the necessary works; also to acquire land and other rights, and supply lamps, meters, and fittings. The district to be supplied is defined

in the notice, which also contains a clause to enable the Company and the Corporation to enter into agreements as to supplying electricity, breaking up roads, &c., and, if necessary, to authorize the Corporation to exercise any of the powers proposed to be conferred upon the Company. The usual authority as to levying rates and charges is sought. The Liverpool Electric Lighting License of last year is to be amended or revoked.

LONDON ELECTRIC SUPPLY.—The London Electric Supply Corporation, Limited, intend applying for sanction to supply electricity for public and private purposes to the extensive area constituting the following parishes and districts:—The parishes of St. Martin-in-the-Fields; St. Margaret and St. John (united), Westminster; St. James, Westminster; St. George, Hanover Square; Chelsea; St. Mary Abbots, Kensington; Paddington; St. Marylebone; St. John, Hampstead; St. Pancras; St. Mary, Islington; St. James and St. John (united), Clerkenwell; St. Leonard, Shoreditch; St. Luke and St. George-in-the-East; the Strand district; St. Giles; Holborn; Whitechapel; the City of London and the Liberties thereof; Lincoln's Inn; Gray's Inn; the Inner and Middle Temple; all the County of Middlesex; Greenwich; the parishes of St. Mary, Rotherhithe; St. Mary, Lambeth; St. Mary, Newington; St. George-the-Martyr, Southwark, and St. Mary, Bermondsey; the districts of St. Olave, St. Saviour, and Christchurch in the county of Surrey. The Company propose constructing a central station at which the electricity will be generated, and a system of distributing stations and mains; and they seek for authority to acquire all the necessary plant therefore. Permission is asked to enter into arrangement with local authorities in regard to the breaking up of streets, &c.; to make contracts to supply such bodies with electricity; and to apply for the above purposes the funds of the Corporation and the money to be borrowed under the Order. The applicants propose to take powers to cross the Thames by the bridges of the London and Brighton, South Eastern, and Chatham and Dover Railway Companies, to interfere with various tramways and railways, to levy rates and charges, and for other purposes.

METROPOLITAN ELECTRIC LIGHTING.—The Metropolitan Electric Supply Company, Limited, have notified their intention of applying for Provisional Orders having reference respectively to North London, South London, Mid London, and West London. In the notice relating to the first-named district, the Company wish to be authorized to distribute electricity in the parishes of St. James, and St. John, Clerkenwell; St. Mary, Islington; and St. Pancras and St. John, Hampstead. The proposed South London Order embraces Lambeth, Streatham, and Clapham. In the notice referring to Mid London, the Company contemplate supplying electricity to a very wide area, comprising the parishes of St. John the Evangelist, Westminster; St. Margaret, Westminster; St. George, Hanover Square; St. Giles-in-the-Fields; St. George, Bloomsbury; St. Andrew, Holborn-above-Bars; St. George-the-Martyr; St. Sepulchre, Saffron Hill; Hatton Garden; Ely Rents and Ely Place; the Liberty of Glasshouse Yard; St. Anne, Soho; St. Paul, Covent Garden; St. John the Baptist, Savoy, or precinct of the Savoy; St. Mary-le-Strand; St. Clement Danes, and the Liberty of the Rolls, together with the Charter House, Gray's Inn, Lincoln's Inn, Staple Inn, Furnival's Inn, and the Close of the Collegiate Church of St. Peter. Authority is sought in the proposed West London Order to supply St. Marylebone, Paddington, and St. Mary Abbots, Kensington. The various powers required by the Company, as set forth in each of the notices, are similar in almost every respect; and, stated shortly, they are to authorize the Company to produce, store, and supply electricity, to construct works, break up and interfere with streets, &c., purchase lands, patent rights, &c., to make agreements with local authorities, to levy charges for the supply of electricity, to apply the funds of the Company to the purposes of the Orders, and to sub-divide, if deemed necessary or expedient, the area of supply.

NOTTING HILL ELECTRIC LIGHTING.—The Notting Hill Electric Light Company notify their intention of making application for power to supply electricity in the parish of St. Mary Abbots, Kensington. For this purpose they ask for authorization to acquire lands, and to construct the necessary works. Provisions as to rates and charges, and making arrangements with local authorities, are comprised in the notice.

STRAND ELECTRIC LIGHTING.—The House-to-House Electric Light Supply Company, Limited, ask for authority to supply electricity in the streets, thoroughfares, and houses in the Strand district; and the powers necessary to carry out this proposal are desired.

SWANSEA ELECTRIC LIGHTING.—The Corporation of Swansea notify their intention of applying for power to produce, store, and supply electricity within the borough; and for this purpose to acquire land, construct the necessary works, lay down wires, &c.

WESTMINSTER ELECTRIC LIGHTING.—This is a proposal by the Westminster Supply Corporation, Limited, to obtain authority to produce and supply electricity for both public and private purposes in various parishes (named in the notice) in the City and Liberties of Westminster and the Strand. Authorization is sought to fix charges, to acquire lands, to make arrangements with local authorities, to open streets, and to lay wires.

NOTICE OF APPLICATION TO THE LOCAL GOVERNMENT BOARD (SESSION 1889) UNDER THE PUBLIC HEALTH ACT, 1875.

ROSS IMPROVEMENT.—It is intended by the Ross Improvement Commissioners to make application for power to purchase the private gas-works existing at Ross, and to carry on the business generally of gas manufacturers and suppliers. For this purpose, the applicants desire to be allowed to borrow money.

UNLAWFULLY USING GAS AT DERBY.—On Tuesday last, at Derby, Henry John Robinson was summoned by the Derby Gas Company, that between the 9th of October and the 15th of November he did unlawfully use and burn gas supplied to his premises by the Company. A fitter in the employ of the Company deposed that on the 9th ult. he went to the defendant's house to take the state of the meter, and to cut the gas off. He unscrewed the connection, and put a cork in the pipe. The state of the index at that time was 253. Another of the Company's workmen stated that on the 15th of November he examined the meter. The cork had been taken out and gas had been used, the index registering 303. Defendant denied that he had unstopped the meter; and said he had no notice that the gas was going to be stopped. He was sure he never took any cork out, and alleged that the gas burned as usual after it was supposed to have been stopped. He called his daughter, who said the gas was lit immediately after the first workman had gone, and burned as usual. This man, however, said he tried the gas after he had stopped it, and found there was no supply. The Company's collector said the supply was stopped owing to the defendant becoming bankrupt. The Company did not wish to press the case, but they desired to deter others from doing the same thing. The Bench inflicted a fine of 20s. and costs, in all 29s. 6d.

Miscellaneous News.

THE HALIFAX GAS SCANDAL.

The event of last week, as far as Halifax Gas Affairs are concerned, was the seizure on Tuesday—at the offices of Mr. Carr's Solicitors—of the press-copy sheets containing coal tests, which are to be the subject of a criminal examination against Mr. Carr at the forthcoming Leeds Assizes. The *Halifax Courier* understands that last Thursday week (the day before Mr. Carr answered to the charges made against him at the Borough Court) some negotiations were entered into by which Mr. Alderman Horsfall made a proposal to Mr. Storey, that if he gave up the whole of the missing leaves, the Mayor, representing the Corporation, would not press the case against him for mutilating the test-book. For some reason or other, these negotiations were not successful; and so the case was heard and sent for trial. In the course of the hearing, it will be remembered, the chief clerk at the gas-works admitted he had spoiled perhaps 8 or 9 of the leaves in the test-book, leaving about 70, all of which Mr. Carr's Counsel said would be produced. Only three, however, were produced, as samples of the rest. Nothing more transpired; and it was understood by most people that the prosecution would have to go to the Assizes without the missing leaves in their possession. On Tuesday morning, however, a somewhat daring, and a very unusual course was resorted to. On the application of the Town Clerk, Mr. J. H. Swallow, J.P., issued a search warrant; and, armed with this, Detective-Inspector Newburn, accompanied by the Mayor and Town Clerk, drove up to Mr. Storey's office. Mr. Storey and his partners were all away—only two boys being within. There were 79 pages missing from the book in question, 70 of which Mr. Storey was understood to have; and the whole of these were seized by Inspector Newburn and taken to the Town Hall. As soon as they were found, the Mayor and Town Clerk drove off; the Inspector remaining behind until Mr. Storey's return.

The following correspondence—sent to the local press by Messrs. Storey and Co.—has been published, accompanied by a brief prefacing letter in which Mr. Carr's Solicitors say: "The unprecedented and questionable course taken by the Mayor and Town Clerk of entering our offices on Tuesday last, accompanied by Detective-Inspector Newburn, leaves us no alternative but to ask you to publish the following letters, to which we have received no reply." The letters are all addressed to the Town Clerk, Mr. Keighley Walton:—

Halifax, Nov. 24, 1888.

Dear Sir,—Although Counsel only put in four or five of the missing sheets, it must not be inferred that the remaining sheets at all affect the Corporation or its funds; and as an impression has been allowed to go abroad that the sheets were kept back because they implicate our client, we are quite prepared to furnish you with copies of the whole of them, in order that you may see that there is not a tittle of evidence of fraud of any kind against our client. He courts, and will require, the fullest investigation into the matter; and does not wish it to be said that he has concealed anything. A perusal of the sheets or copies thereof will, we think, convince you and the Mayor of our client's innocence.

At any rate, after you have had the opportunity of examining what we are prepared as above to furnish, you will doubtless feel it your duty to point out, if you can, anything which you think constitutes fraud, and to give us notice thereof, so that we may be prepared to deal therewith.

We repeat what we have all along said, that the sheets relate solely to private analyses, and do not affect the Corporation in any way.

Your reply in the course of to-day or Monday will oblige.—Yours truly,
(Signed) STOREY & Co.

Halifax, Nov. 27, 1888.

Dear Sir,—We enclose you a letter, which was written previous to our Mr. Storey's leaving the office this morning, and only awaited the completion of the transcripts to be forwarded to you. We think you had better have it, in order to show that we are acting in good faith.

We have also to request that you will give us an opportunity of completing the transcripts and examining them with the press copies.

With regard to your action this morning, we may have something to say later on.—Yours truly,
(Signed) STOREY & Co.

[Enclosure.] Halifax, Nov. 27, 1888.

Dear Sir,—We have now made transcripts of the press copies of leaves taken from the letter book, with a view to hand such transcripts to you, as promised; but as it may be more satisfactory to you to have the original press copies instead of the transcripts, we now hand the whole of them to you.

In doing so, we think it due to our client to say that he has all along regarded, and still regards, the information contained therein to be his private property, as it has no reference to any matter connected with the Halifax Gas-Works. He most distinctly and emphatically disclaims any felonious or fraudulent intent whatever in instructing the clerk (Milner) to remove the leaves from the book. In regard to the few pages which appear to be missing, our client is unable to give any information respecting them. He can only suppose they may have been injured or destroyed in the process of making copies, as was admitted by Milner, who made the copies, to be quite possible. At any rate, they are not, and never have been, in our client's possession.—Yours truly,
(Signed) STOREY & Co.

It is understood that Mr. Carr's case will come on for trial at the next Leeds Assizes, which commence on the 10th inst.

THE GENERAL GAS COMPANY OF FRANCE.

In the report presented by the Directors of this Company at the annual general meeting on the 23rd of October last, they stated that during the twelve months ending June 30 they had been subjected to competition with the electric light in several of the French towns, whereas previously this competition had only been experienced at Tours. The receipts, however, and consequently the profits, had not fallen off; on the contrary, the accounts showed that they had considerably increased as compared with the preceding year. This fact would, the Directors thought, have the effect of removing any apprehensions to which the competition of electricity might give rise in regard to the future of gas. In addition to the works already possessed by the Company, two others (at Brest and at Piræus) were acquired towards the end of the financial year; but, of course, they had little effect on the result of the working. The capital account was thus increased from 27,557,352 frs. to 30,913,990 frs. The profits resulting from the works possessed by the Company amounted to 714,824 frs.; the interest accruing on the investments in other undertakings, to 1,505,094 frs.—making a total of 2,219,378 frs. and being an increase of 142,337 frs. on the profit for the preceding year. Adding to this the balance brought forward (630,211 frs.), made a total of 2,849,589 frs. Taking from this sum the general expenses, interest, and the payment

to the sinking fund—in all, 756,964 frs.—there was left a net balance of 2,092,625 frs. After making the various deductions for the reserve fund, Directors' fees, &c., there was left a sum of 968,896 frs. available for division among the proprietors. The Directors recommended that 200,000 frs. of this should be distributed as dividend, and the remainder carried forward. This would allow a dividend of 30 frs. per share. The statutory reserve fund was brought up to 470,375 frs.; bonds and other securities to the amount of 512,500 frs. were paid off; and there was left to the good 768,896 frs. The above-named dividend was declared. In order to meet the expenditure necessitated by the increasing business of the Company, the Directors were authorized to raise additional capital to the extent of 5,000,000 frs. by the issue of bonds.

ORIENTAL GAS COMPANY, LIMITED.

The Ordinary General Meeting of this Company was held last Wednesday, at the London Office, 14, St. Mary Axe, E.C.—Mr. H. M'LAUCHLAN BACKLER in the chair.

The SECRETARY (Mr. A. Hersee) read the notice convening the meeting; and it was agreed to take as read the report of the Directors and the statement of accounts for the year ending June 30 last, an epitome of which appeared in the JOURNAL for the 20th ult. (p. 899).

The CHAIRMAN: Gentlemen,—I have now to make a few remarks; and they will be but few, because there is very little to say. The report itself, though not a long one, deals with the principal subjects that have been under the consideration of the Directors during the year, apart from the ordinary daily management to which they give their attention. In the first place, as regards the accounts for the twelve months, there is nothing particular in them, except, I am sorry to say, a further increase of the rate of exchange, which has caused us an additional loss of £1337. This, as you know, we have not the slightest power over. It is very discouraging I must say to us (as it must be to all others who have money to receive from India) to find that, notwithstanding the endeavours made to improve the position of the Company to a higher state of success than that which it has attained—although that is very satisfactory—all these efforts are annulled by such a circumstance as this, and a circumstance which seems to be interminable, so far as I can tell, at all events. We have lost, as I have said, £1337 more than we did before; and consequently, although we have an increase of revenue, and although the greatest exertions have been made by our able Manager, Mr. Niven, to add to the business of the Company, and with some success, still this is all annulled by the increase in the rate of exchange. This we cannot help; and therefore it is no use remaining any longer on the subject. I will now proceed to make a few remarks on the accounts in other particulars, which, however, are of less importance than that which I have mentioned. You will see the capital outlay is very small indeed this year. I commented last year on the smallness of the amount; but it is still less on the present occasion. I am sorry it should be so small, because, as I then said, if we had to spend money out of our capital, it would be because that capital would be more productive by the expenditure incurred. We are therefore, pretty nearly at a standstill, although not entirely so, as you see by the additional receipts which we have had for gas. Then another item in the accounts which would attract the attention of those among you who are well acquainted with gas matters—and I know there are several—is the additional expenses for coal. You would naturally say, "You have spent so much more on coals—about £1400 more—and yet the gas-rental has only increased by £983." I will explain this circumstance to your satisfaction. In the first part of the year, we found our coke was selling readily; and we thought it would be advantageous to use coal instead of coke in the furnaces for the heating of the retorts. We did this; and it was very satisfactory indeed. We should have continued to do so; but, later in the year, we found that an inferior quality of coke was being introduced into the Calcutta market which was the product of coal dross from the collieries, and was brought down cheaply to Calcutta. The inferior quality of it, however, would always prevent it from being a serious competitor with the gas coke we produce. But at the same time, the Indian natives are not so particular as we should be; and if they can get anything cheaply, that is sufficient inducement to them to use it, which they did in this case to some considerable extent—so much so that our stock of coke increased towards the close of the year; and we thought it necessary then to suppress the use of coal, and return to the employment of coke as fuel. This we may alter again as circumstances require. You will see by this that Mr. Niven, who has the direction of these matters at Calcutta, has not been unmiudful of our interests, and that he has done all in his power to meet the difficult circumstances of the case as they arose. With regard to the other side of the capital account, we have paid off £935 of debentures, which fell due, and which we did not renew, though perhaps we may do later on. We have added £1000 to the reserve account; and altogether the financial state of the Company is on an excellent basis. Passing on to the other paragraphs of the report, you will observe, of course, that there is an increase in public lighting. The addition is not very large; but at the same time we cannot expect a great increase in public lights, as has been explained to you frequently before. The extent of public lighting depends entirely upon the amount of rate voted for this purpose. If the rate produces a large sum, then the Company are likely to get more public lighting; but if it remains at a standstill, then we do not get any additional benefit. I should mention with regard to public lighting, that in Calcutta it is remunerative, which is not the case in many instances, especially in other companies working abroad in which many of us here are interested. With regard to private lighting, I think it is satisfactory. We have had 179 new consumers, and 1423 burners added. The increased quantity of gas consumed during the year has been used by the natives. I am pleased to see this door opened, because, once opened, I believe it is there we shall find the additional profit which we hope to derive from the extension of our business. No doubt this is a difficult matter; and Mr. Niven has had his attention drawn specially to it—not that he requires reminding, because he is most zealous in endeavouring to extend the Company's business. Then as to the Company's works, Mr. Niven reports that they are in a satisfactory condition, and the apparatus and holders are in good working order. Turning again to the accounts, there are several items which are not exactly the same as last year, though they do not differ very materially. Referring to mains account, wear and tear and repairs, and retort account, they all show differences from the previous year; but, taking the whole of the items together, you will find that the difference is only about £17. We have a staff of men who are employed according to the requirements for their labour—sometimes it may be for one thing and sometimes for another. And this is the only reason for the differences you may have noticed in these items: The men have been differently employed to what they were in the previous year; consequently, the sum being the same, the details are somewhat different. The extension of mains by 2200 yards does not require comment. I only wish it had been much more than this. We have in

Calcutta, as you are aware, an able Committee, composed of two gentlemen, who have rendered the Company good services. We have not had occasion during the past year to call for any special effort on their part to serve us; but their vigilance has been constant and successfully exercised. They work in perfect harmony with Mr. Niven; and you know how necessary it is that all who are engaged in one undertaking should work well together—it is very difficult to achieve success without it. The next thing I have to refer to is the death of our late friend Mr. W. White, which we all felt very much indeed. He was a regular attendant at the Board meetings; and he was most anxious to devote himself to the interests of the Company at all times. We have lost a good friend in him; and our Company, an able adviser. Of this we have acquainted the family; and we made bold to think the shareholders would associate themselves in it. On the death of Mr. White, it was incumbent upon us to elect another Director; and we turned immediately to one of the Auditors (Mr. H. L. Hammack), who has been a candidate for the office for some years. This gentleman unites in himself all the qualities necessary to make an able Director of this Company. We have already found that we were fully justified in nominating him to this post; and it will be for you to confirm this nomination. Mr. Hammack, who is a son of one of the original Directors of this Company, is a Director of the Commercial Gas Company; and his knowledge of gas affairs, combined with his well-known business and administrative abilities, will commend themselves to you as they did to us. Mr. Hammack having resigned the position of Auditor, which he has held, with great satisfaction to us, for some years, there was a vacancy which we were bound to fill up. The applicant for the office was Mr. J. Blacket Gill, who has been a candidate for several years. Mr. Gill is also the son of one of the original Directors of this Company; and he is likewise a Director of the Commercial Gas Company. The experience which these gentlemen have acquired in connection with the Commercial Company will, I am sure, be brought usefully to bear upon the management of our affairs. Passing to the balance of the general revenue account—that is, the profit after all deductions—there is sufficient to pay the same dividend as last year. It is a large amount—£27,155—and it will leave a good balance to the credit of this account after we have paid the dividend. I therefore think we may congratulate ourselves on the position of our affairs, notwithstanding the circumstance to which I have alluded in my opening remarks. Reviewing what I have said, the business which we are doing is a good substantial business; and apart from all the adverse circumstances which arise, whether it be from competition in coke, or whether it be the bad state of business (which affects people in Calcutta, as elsewhere) or whatever the adverse circumstances may be, I hope we shall still maintain our position—we hold our own, as is familiarly said; and if we do this under adverse circumstances, with the rate of exchange as it has been, we may reasonably hope in future, with the increase arising out of the sale of gas, that we shall derive a very great benefit, which will counterbalance the adverse effect of the exchange, and will enable us to look with certain hope to brighter days than we have experienced in the past, however satisfactory those days may have been. I now beg to move—"That the report of the Directors and the statement of accounts now submitted be received and adopted."

Mr. H. SOLOMON seconded the motion, which was at once carried unanimously.

On the motion of Mr. C. HILL, seconded by Mr. J. R. PEILL, the retiring Directors (Messrs. H. M'L. Backler and H. L. Hammack) were re-elected. The CHAIRMAN and Mr. HAMMACK having thanked the shareholders for re-instating them on the Board,

The retiring Auditors (Messrs. E. Garey and J. Blacket Gill) were re-elected, on the proposition of Mr. EASTMAN, seconded by Mr. T. HILL.

The CHAIRMAN next moved the declaration of a dividend of 10 per cent. for the twelve months ending June 30th last, to be payable, free of income-tax, on Dec. 4, less 4 per cent. paid on account on June 4 last.

Mr. HAMMACK seconded the motion, which was agreed to.

The CHAIRMAN, in moving a vote of thanks to the Secretary, the Engineer, and the staff generally, referred in eulogistic terms to the services of Mr. Hersee and Mr. Niven.

Mr. SOLOMON seconded the resolution, which was carried *nem. con.*

The SECRETARY having briefly returned thanks on behalf of himself, Mr. Niven, and the staff,

The usual compliment was passed to the Chairman and Directors, and the proceedings terminated.

COCKERMOUTH AND WORKINGTON WATER SUPPLY.—A dispute which has been pending for some time past as to the quantity of water the main leading from Crummock Lake, which supplies the Cocker-mouth Urban, Cocker-mouth Rural, and Workington Urban Sanitary Authorities with water, is capable of delivering, is shortly to be brought to an issue. Under the provisions of the Workington Water Act, 1883, the Cocker-mouth Urban and Cocker-mouth Rural Authorities have applied to the Local Government Board for an engineer to be appointed to ascertain the quantities of water the main is capable of delivering; the Workington Authorities having bound themselves, under their Act of 1883, to take, or pay for, all the water the main can deliver, after the two Cocker-mouth Authorities have obtained what they require, under the provisions of the Crummock Joint Water Act. In response to this application, Mr. H. Robinsou, C.E., has been appointed Arbitrator on the subject; and this gentleman has arranged to take evidence about the middle of December.

THE WATER SUPPLY OF MELMERBY.—Last Tuesday, Mr. Arnold Taylor, Local Government Board Inspector, held an inquiry at Melmerby, near Ripon, with respect to an application to the Local Government Board by the Rural Sanitary Authority of the Ripon Union for sanction to borrow £1100 for works of water supply for the township of Melmerby. Mr. C. F. P. Edmundson, the Clerk to the Sanitary Authority, stated that the present supply of water at Melmerby was obtained from about twenty wells, a number of which were liable to contamination from fold-yards and other places. It was proposed to utilize the Hallikeld Springs, which were about 1000 yards from the village, lifting the water by means of Blake's hydraulic rams to an elevator above the village into a reservoir, whence it would gravitate for use by consumers. The cost of the scheme was estimated at £1057. The population of the township was 305 at the last census. The inhabitants who would benefit by the supply numbered 259; and as the springs ran at the rate of 70,560 gallons per day, of which the hydraulic rams would lift 5547 gallons, the daily supply would be equal to 21½ gallons per head of the population. The Marquess of Ripon had consented to give the land required, on condition that one of his farms was supplied with water; while other interested persons could be dealt with at a reasonable price. The water, as analyzed by Mr. Fairley, was stated to be moderately hard and of good quality. Evidence in support of the application was then given. The Inspector being informed that no charge would be made to consumers for the water, suggested that a rate should be levied upon those who had the benefit of the supply. At the close of the inquiry the Inspector examined the springs whence the supply is to be obtained.

A COMPARISON OF OIL AND GAS AS ILLUMINATING AGENTS.

In connection with an exhibition of oil lighting, heating, and cooking appliances held, during the week ending the 24th ult., in the Holly Park Lecture Hall, New Southgate, Mr. DEFRIES, the well-known maker of safety oil-lamps, delivered a lecture, in which he compared with gas the "economy and superiority" of oil as an illuminating agent.

The lecturer, commenced by remarking that he had been asked to say a few words in order to demonstrate the economy and superiority, in every respect, of lighting by mineral oil, as contrasted with lighting by gas. The task set him, he said, was not at all difficult; for nothing was simpler than to prove, as he was going to, that gas lighting, having now been in use for the best part of this century, and having got to the top of the tree as an illuminating agent, was now past its zenith, and was going down hill, not only on account of the unpopularity of the monopoly it had enjoyed, but because its great rival—mineral oil—was proving uncontestedly its utter superiority in use on the scores of economy, intensity of light, and health. Incidentally he had been told, and had even seen it published in newspapers, commenting on some very successful installations of mineral-oil lamps for lighting towns that he had recently carried out, that in giving up gas and using mineral oil, the local bodies responsible for the change were taking a "retrogressive step," and "going back to the oil-lamps of our grandfathers." Nothing could be more untrue. When he stated that gas-lamps were used in the London streets nearly ninety years ago, and that about forty years since the use of mineral oil was unknown, they could judge if the giving up of gas and the employment in its place of mineral oil was a step backward or forward. He would give some figures, that would prove, he said, beyond a shadow of a doubt, that gas could not compete with mineral oil. He based his calculations on gas at 4s. 6d. per 1000 cubic feet (which was what he believed they paid in that town), and burned in an ordinary burner, and mineral oil at 8d. per gallon—at which price it could readily be purchased—as consumed in a Defries' safety lamp. A Defries' mineral-oil lamp with a No. 1, or 43-candle power, burner consumed a pint of oil in five hours; thus giving a light equal to 43 candles at a cost of 1d. for five hours. A No. 6 Bray's gas-burner was supposed to consume 6 cubic feet of gas per hour; but generally burned 7 or 8 feet. However, he would take it at 6 feet. Burned in this manner, gas was supposed to give the light of 2½ standard candles for each cubic foot consumed per hour. It would therefore be seen that three such burners, consuming 18 cubic feet per hour, were supposed to yield a light of 45-candle power, and to consume in five hours 90 cubic feet of gas, which at 4s. 6d. per 1000 cubic feet, was equal to 4½d., or in plain figures 5d. So they saw clearly that, burned in the best mineral-oil lamp known, and the one in most general use, a given light could be obtained from oil at one-fifth the cost of a similar light from gas. Oil lighting cost therefore one-fifth the cost of gas. There were, doubtless, many persons who, either in their dwelling-houses or their places of business, paid £20, £30, £40, and perhaps £50 a year for gas. The man who was now spending £50 a year for gas lighting could have an equal light from Defries oil-lamps at a cost of £10 a year for oil; and so save £40 of his present annual expenditure.

No form of gas-burner, he continued, had yet been constructed which would perfectly consume all the carbon or sulphur in gas. A few months' experience with gas-burners showed on ceilings, decorations, and pictures that free unburnt carbon came away. The products of half-burned carbon and impurities showed their effect in the death of flowers kept in a room where gas was burning. But a more serious, though less striking mischief, was the effect of gas on the health of its users. In addition to daylight, a pure atmosphere was necessary to enable flowers to live in a room. It was, he said, a fact not properly appreciated that the health of a human being was injured by an atmosphere that was fatal to the life of flowers. It followed very clearly that an ordinary sitting-room lighted with gas, and having an atmosphere in which flowers could not live, was responsible for many of the sufferings of mankind. If they could reckon the total amount of headache and dyspepsia which it had caused, he thought they would arrive at an aggregate of human misery which was simply appalling. On the other hand, mineral oil properly burned, or in other words used in lamps that had practically a perfect combustion, did not vitiate the atmosphere of a room to any appreciable extent. Flowers would live in a room so lighted—picture frames, gilt ornaments, decorations, and furniture were not affected by its use; and the atmosphere of a room so lighted was perfectly wholesome and did not injure the health of a human being.

A great advantage of mineral-oil lighting, as compared with gas lighting, the lecturer said, was that you obtain a softer yet more brilliant, and much steadier light. Now there were many effective methods of lighting rooms by lamps, and results could be produced with them which could not be obtained at all from gas. A good lamp, properly trimmed, burned without a flicker. To light a dining-room properly, the best method was to suspend in the centre of the room a powerful yet shaded single burner lamp of about 60-candle power. The effect produced was that the ceiling was lighted with the soft light of the lamp emitted through the opal glass, while the table and the bottom of the room generally was brilliantly lighted, yet without there being any glare. The colour of the light emitted from a perfect lamp more nearly resembled daylight than any other form of artificial lighting; so much so that, although they might replace a four-light gasolier, supposed to be giving a light of 60-candle power, by a lamp having a 60-candle power burner—actually and not nominally 60-candle power—the room would appear to be better lighted than it originally was by gas. The most effective manner in which to light a drawing-room, was to place a few stand lamps in corners of the room on tables. In a room of (say) 24 feet by 18 feet, three lamps of about 40-candle power each were ample to light the room with a soft, warm light, and to produce at the same time a most charming effect. For the purpose of study or reading, he recommended lamps giving a pure white light of about 20-candle power. His reason was, that such a light was just about ample for the purpose, yet not too little to fatigue the eyes; and, moreover, a burner giving such a light emitted very little heat.

Turning to the question of street lighting by mineral oil, Mr. Defries said this was a matter of the very greatest importance to the ratepayers of the whole kingdom. It was impossible to state (for he had no means of finding out) how many public street lamps there were in the country; but they might be estimated at one per hundred of the population. At Erith, which with its surroundings was not very densely populated, it was 1 to 60. This would give an estimated total of 350,000 public gas-lamps now in use in the kingdom, taking the population at 35,000,000. The gas-burner generally employed was a No. 5, giving a light of about 12 to 13, or (say) 14 candle power, although in many cases a smaller burner was used. The cost per lamp per annum averaged between £3 10s. in large towns to £4 10s. and more in small towns. Taking it that they all cost £3 12s. 6d., each lamp burning every day in the year from sunset to sunrise, the price being inclusive of the necessary labour to light and extinguish and clean the lamps, they found the sum annually expended in the United Kingdom for street lighting was £1,268,750. Now, it was admitted that the light given was not sufficiently powerful, and yet the price paid was by nearly every district already considered most excessive.

He would show how more than double the light at present obtained from gas could be obtained from mineral oil, and at the same time a saving of more than a third effected in the whole of this cost for the "inferior" gaslight. The system which had been found to answer its purpose well, by means of which lamps, independent of each other, may have a reservoir placed high above the burner, and if necessary hold enough oil to burn a week with once filling, was the joint invention of two gentlemen, and was worked by the Company with which he (the lecturer) was associated. The idea of the inventors was to so construct a lamp with a reservoir of any width, but of a given height, that it should supply its oil to a burner fitted on a wick case, which wick case should be provided with a space for the flow up it of a head of oil equal to the head in, or the height of, the reservoir. The equilibrium had, of course, to be maintained; and they found that the finest spring they could use that would exert an equal and unvarying pressure on the head of oil in the reservoir and the head of oil in the wick case was a column of air, which was being constantly changed. By the simplest of all natural means, they had constructed, in accordance with these principles, what might be, he thought, considered a perfect lamp, which had no vacuum, and burned in consequence equally well whether hot or cold, and had not a single moving part in it, and so could not become deranged. This was the system that was considered by many Local Boards, in addition to scientists who were well able to judge, as rendering street lighting, by means of mineral oil, not only a possibility, but an accomplished fact. He might mention that they had 15,000 to 16,000 of these lamps now out in use; each, with a reflector, giving a light of about 30-candle power. He had proved, by the work done in the districts referred to, the exact cost of maintaining the lights, providing the oil, labour, &c.; and he found it to be, as nearly as possible, 47s. per lamp per annum, supposing the lamp burned from sunset to sunrise every day in the year.

In concluding his remarks, Mr. Defries said that mineral oil was capable not only of theoretically lighting the public streets, but was practically doing it. He had estimated the number of existing street gas-lamps of 14-candle power at 350,000; and their annual cost to the ratepayers at £1,268,750. The same number of mineral-oil lamps, yielding more than double the light at present given by the gas-lamps, would cost only £822,500; and the ratepayers had it in their power, therefore, to at once save an annual outlay of £446,250, while doubling the light in the streets. Surely, he observed, this was proof enough of the absolute superiority of mineral oil, burnt in suitable lamps, over gas. The saving by the change was not so large as it was to private consumers; but, of course, labour was a large item in street lighting, and his proposal was to give double the light of the gas-lamps. In any case, towns that now paid £4 10s. for gaslight, could save by this change nearly half their present outlay.

The proceedings closed with a vote of thanks to the lecturer.

THE HARGREAVES THERMO-MOTOR.

A CREOSOTE ENGINE.

At one of the recent Meetings of the Liverpool Polytechnic Society, Mr. J. HARGREAVES, of Widnes, described, by the aid of a sectional model, his new thermo-motor.

Mr. HARGREAVES, in his opening remarks, said that in a steam-engine there were two great sources of loss—First, there was the loss in the boiler where the products of combustion were sent into the air at a high temperature, the heat necessary for which was all wasted; and, secondly, there was the loss to the engine due to the latent heat being taken away by the condensing water. For these reasons there was only about 12 per cent. of the total heat utilized; all the rest being thrown away. In the engine he was about to describe, he claimed that he obtained a larger duty from the fuel by burning it in the cylinder itself, so that all, or nearly all the heat generated by combustion might be extracted from the fuel before it was rejected. Very high temperatures might be employed; and the higher the temperature, the greater the efficiency. Commencing at the air pump, water was injected into it to reduce the temperature of the air, and, by vaporization, to increase the pressure. The mixture of air and water vapour was then passed into the saturator, where it was still further saturated with water vapour if necessary; but in practice it was unnecessary. After leaving the saturator, the mixture of air and water vapour passed into the superheater, where it was heated by waste gases. It then flowed through a regenerator filled with pieces of earthenware into the combustion chamber, where it met with a jet of limpid fuel, and was burnt at a very high temperature, and, consequently, with great increase of volume and pressure. The combustion chamber was lined with non-conducting material, so that the quantity of heat passing to the exterior walls of the combustion chamber might be regulated, and the interior of the chamber kept at a sufficiently high temperature to ensure perfect combustion of the fuel. Attached to the top of the combustion chamber was a metal cylinder, within which worked the main piston. The waste products of combustion passed out through the regenerator; giving up nearly all their heat—the temperature when leaving the regenerator being only about 350° Fahr. They then flowed through tubes in the superheater and saturator; giving up the remaining heat so thoroughly to a fresh supply of air and water vapour that the temperature of the escape-pipe was only about 180° Fahr. All rubbing surfaces, he remarked, must be kept at a reasonable temperature, or else a tight joint could not be obtained.

Attention was then drawn by Mr. Hargreaves to the water-jacket of the engine. In a gas-engine the cylinder was kept cool by a water-jacket; and all the heat taken up by the jacket was lost. The combustion chamber of his engine was jacketed much in the same manner; but it was made to generate steam so long as the inner surface of the combustion chamber was not cooled below a certain temperature. The water to supply the jacket was first taken through a hollow space in the piston, which it kept cool; and then into the jacket, where it was converted into steam. The jacket was in connection with a small supplementary boiler, which could be fired in the ordinary way when first starting, in order to get power to compress a supply of air for the main engine. The steam from the jacket, after passing through the small boiler, was led to the saturator, where it was injected into the mixture of air and water, until there was altogether about 30 per cent. of water vapour mixed with the air. Air at a comparatively low temperature containing this quantity of vapour would not support combustion, but when the mixture was highly superheated, as it was in passing through the regenerator, it would burn. The mechanical arrangement of this engine might be of any convenient kind. There seemed to be an impression that the engine was a very complicated one; but really it was not so complicated as an ordinary steam-engine. He was making another engine somewhat similar, in which there was only one superheating nozzle used; but, otherwise, it was much the same as the one before them.

In reply to various questions, Mr. Hargreaves said that about 20 per cent. of the indicated horse power was used in driving the engine itself. For starting the engine, a small portable furnace was used to heat the combustion chamber, and to compress a charge of air; and steam was got up in the small supplementary boiler, which worked a donkey-engine and

air-pump. For small engines a hand air-pump might be used. The complete engine, as he had described it, would be more economical than the simpler form. He could get 40-horse power with a consumption of two gallons of creosote per hour. In his experiments, the temperature in the engine had risen so high at times as to melt the bottom of the piston, and fuse the earthenware blocks in the regenerator. To get the best results, an extremely high temperature must be used. It was a question of properly proportioning the thickness of the non-conducting material to prevent the cylinder lining being melted. The regulation of heat was to a certain extent automatic, for when the temperature of the combustion increased, there was more steam generated in the jacket, which steam increased the proportion of water vapour in the air and so lowered the temperature of combustion. If too much steam was generated, the temperature would be too low, and more heat would be carried away, because all the heat of vaporization could not be recovered. All the heat in the steam in a latent form was lost. It was more economical to use air; but if air alone was used, the temperature became so high as to melt the whole interior of the engine. However, by making the non-conducting material of proper thickness, the engine became self-regulating by means of the difference in the generation of steam, which might become so large as to put the fire out if the non-conducting material were not properly proportioned.

In the course of the discussion which ensued,

Mr. MILLER remarked that the heat in the jacket of the Britton gas-engine was not lost, because the jacket was used to generate steam, which was utilized in the engine by mixing it with the gas and air, to be burnt just in the same manner as in the Hargreaves engine. He understood the Britton gas-engine worked better with the mixture of steam and gas than with gas alone.

Mr. HARGREAVES said in the gas-engine referred to, the steam was obtained at the cost of reducing the temperature of the cylinder much below that of the best gas-engines. No regenerator was used; and all the latent heat of the steam was lost. In his own engine, the volume of steam was increased about four times in passing through the regenerator alone; so that four times more work was obtained by superheating the steam than by using it simply as steam. It was a prominent feature of his engine to use it as a "red-hot" steam-engine.

Professor SHAW considered that the Hargreaves engine was one of the most interesting things going at the present time. One of the greatest difficulties to get over was the question of durability of materials.

Mr. J. JOHNSON asked if Mr. Hargreaves had tried chromo iron; it would stand very high temperatures.

Mr. HARGREAVES replied that he had not found anything better than China clay blocks for filling the regenerator, and good cast iron for the metal parts. He would be glad if someone could discover some material having the infusibility of fire-clay and the tenacity of iron. Asbestos, no matter of what quality, was of no use; as it all became very brittle and powdery when highly heated. Chromo iron would stand a high temperature; but there was also the question of standing the vibrations and shocks when working. There was one thing he had not pointed out, and that was the advantage he obtained by mixing water spray with the air. It was a law that if liquid, at a certain temperature, was exposed to air at the same temperature, the vapour of the liquid added its own pressure to that of the air. For instance, if air was heated in a vessel from 32° to 212° Fahr., the pressure would at first remain at 5 lbs.; but by agitating or spraying the water so that its vapour could be absorbed by the air, the pressure would be increased to about 20 lbs. per square inch above the atmosphere. In this way heat was recovered that could not be possibly utilized by any other means. It was the latent heat that was utilized.

A vote of thanks was accorded to Mr. Hargreaves, who, in acknowledging it, remarked that he had still more details to work out before he could give the members of the Society a full and complete paper on the subject.

We understand that the Widnes Foundry Company have constructed one of the Hargreaves motors; and it is now driving the machinery in the boiler-shop. It is said that with a daily consumption of ten gallons of crude oil, the cost of which is quoted at 1½d. per gallon, it does the work which, with an ordinary engine, previously required 25 cwt. of coal.

HOYLAND SILKSTONE COAL AND COKE COMPANY, LIMITED.—This Company was registered on the 17th ult., with a capital of £70,000, divided into 7000 shares of £10 each, to acquire as a going concern the business of a colliery proprietor and coke manufacturer, now carried on by Thomas Henry Birch, Jacob Higson, and John Higson, at Hoyland, in the parish of Wath-upon-Deane, in the county of York.

RIPON WATER SUPPLY.—A meeting of the Ripon City Council was held in Committee, last Wednesday, to consider the progress of the new water-works at Lumley Moor, now completed with the exception of the filter-beds. The Engineer (Mr. R. Carter) stated that the first filter-bed would be completed in a day or two; and after some discussion as to the desirability of turning on the supply, it was resolved, by the casting vote of the Mayor, that the water should be turned on at Lumley Moor on the 10th inst. Subsequently, the Water Supply Committee decided to invite the ex-Mayoress (Mrs. Baynes) to perform the ceremony.

THE PUBLIC LIGHTING OF BRISTOL.—During the recent discussion as to the proposal of the Bristol Gas Company to adopt the sliding scale, attention was directed to the cost of public lighting in the city; and at one of the meetings of the Sanitary Committee, when the matter was under discussion, a question was asked as to whether the time had not arrived when steps should be taken to introduce electric lighting in the main thoroughfares. In reply, it was stated that at the present time the electric light was much more expensive than gas, but that the subject would continue to receive the consideration of the Electrical Committee appointed by the Council. In this connection, the following figures, giving the cost of the public lighting during the three months ending September last, will prove interesting. The price of gas supplied to the street lamps was 2s. 2d. per 1000 cubic feet. The number of public lamps with No. 5 burners was 4853; with No. 7 burners, 16; with No. 10 burners, 4. There were also 16 large lamps consuming 18 cubic feet per hour; one, 15 feet; 111, 21 feet; 33, 25 feet; and 11, 33 feet. The total consumption of gas during the quarter, including the new lamps erected, was 28,216,787 cubic feet, divided as follows:—Consumed by ordinary lamps, 24,230,966 cubic feet, costing at 2s. 2d. per 1000 cubic feet, less 5 per cent. discount, £2499 19s.; consumed by large lamps, 3,925,821 cubic feet, at 2s. 2d. per 1000 feet, less 10 per cent., £382 15s. The expenditure for lighting, extinguishing, cleansing, and repairs, &c., to 5050 lamps, at 15s. per lamp per annum, amounted to £946 17s.; for lighting, extinguishing, and cleansing new lamps erected during the quarter, £2 4s.; for new services and alterations to lamps, £84 6s. 7d.; and for gas consumed at offices and hospitals, £3 7s. 1d. The foregoing sums added together make a total of £3919, which was the cost of the public lighting during the three months named.

EDINBURGH AND LEITH GAS COMMISSIONERS.

At the Meeting of the Edinburgh and Leith Gas Commissioners yesterday week—Provost ARKEN (Leith) presiding—a variety of matters occupied the attention of the members.

The Works Committee reported the termination of the strike at the Leith Gas-Works, and that alterations in the working hours and wages of the men had been made, which, if continued during the whole year, would entail an increase of about £1750 in the working expenses. Bailie Archibald briefly explained the position of matters, and the result of the strike. The total number of men, he said, who gave notice was 156; but five withdrew their notice; leaving 151 who went out on strike. Of these, 89 had been taken back; and this left 62 of those who gave notice still unemployed. The retort men had claimed 6½d. an hour; and the Committee recommended that their wages should be raised to the scale before the reduction in May, 1886. They struck work, however, not because they did not get what they wanted, but in the interests of the labourers; and the Committee had authorized the Engineer to raise the wages of first-class labourers to 5d. per hour. The increase of £1750 in working expenses was estimated on the assumption that the hours of labour would be reduced from 56 to 51 per week; but it was believed that by employing only good men, they would get as much work in the 51 hours as in the 56 hours formerly, so that the increase would not be nearly so great. Replying to Mr. Robertson, Bailie Archibald said he had no information as to whether or not the ringleaders of the strike had been taken back; and the Sub-Committee had given no instructions in this matter. It had been left entirely with the Engineer. On the termination of the strike, they had intimated to the Engineer that, although the men had acted rather precipitately, a preference should be given to them over strangers when any vacancies occurred.

With regard to the application for a supply of gas to Colinton (see *ante*, p. 728), the Works Committee recommended the Commission to introduce gas, on receiving a guarantee from two mill-owners to use gas for five years, the terms to be 4s. 2d. per 1000 cubic feet during the first three years, and 8d. beyond the Edinburgh rate for the next two years. The report was approved; and the guarantees having been received, the estimate of Messrs. McLaren, of Glasgow, for the new main pipe was accepted—the price being £4 6s. per ton.

The next matter under consideration was the insurance of three gasholder stations; and it was remitted to the Finance Committee to effect insurance for £38,000. It was stated that the annual premium would be only about £65.

The acceptance of an offer received from Glasgow, to buy 1500 tons of coke, at 4s. 9d. per ton, was recommended by the Works Committee. Mr. Kinloch Anderson complained that they were selling coke at such a low price to Glasgow people, while they were charging double that rate to Edinburgh purchasers. Bailie Steel stated that coke was sent from Glasgow to Edinburgh, and sold at a lower price than the Commissioners were charging; and if they had a market for it at their door, he did not see that they should send it to Glasgow. Mr. Colston said that there were about 2500 tons of coke in stock at the time; and it was with the view of getting quit of it, that they had accepted this offer. The recommendation was then agreed to; and the whole question of the price of coke in future was remitted to the Works Committee.

A letter was read from Mr. Dewar, Superintendent-Surveyor, in which he stated that, after considering the working of the establishment, he thought the best thing for the peace of the office would be his retirement from his present situation; and he claimed, under the provisions of the Act of Parliament, a pension of £250 per annum. A conversational discussion arose on the matter, in the course of which Mr. Pollard suggested that, as there was a dispute between Mr. Dewar and the other officers, the matter had better be remitted to a Special Committee. Mr. Kinloch Anderson stated that the cause of the difference was that they had tried to make a place for Mr. Dewar when there was not an opening for him. The letter was sent to a Special Committee for consideration.

A statement in regard to the public lighting was subsequently made by Bailie Archibald, in the course of which he said that the Works Committee were unanimous in their opinion that burners should be supplied to all the public lamps by the Commission; but until they learned at what price gas was to be supplied to the Corporations, they could not decide as to the description of burner. There were great complaints in Edinburgh and Leith—especially in Edinburgh—as to the public lighting. He had been making some inquiry into the matter; and he had the concurrence of the Engineers in suggesting that the price of gas for the public lamps should be 2s. 6d. per 1000 cubic feet, without discount. If this were agreed to, it would enable the Corporations to supply No. 2 patent jets, which burn 2 cubic feet per hour, or about 8000 feet a year; and the charge for each burner would be 20s. They would have 2 cubic feet of gas per hour, instead of 1½ feet as at present; and this would make a very great difference in the public lighting. With the low price of coal, and their present favourable position, he thought they should decide the matter at once; and he therefore moved that they reduce the price of gas supplied to the public lamps to 2s. 6d. per 1000 cubic feet, and supply burners free of charge—leaving it to the Corporations to determine what burner they should use. The present rate for a No. 2 burner was 27s. 5d., less 2½ per cent. discount, or, as nearly as possible, 3s. 3d. per 1000 cubic feet net; so that his proposal meant a reduction of 9d. Bailie Turnbull seconded the motion, which was unanimously agreed to.

ELECTRIC LIGHTING AT BARNET.

At the Meeting of the Barnet Local Board last Tuesday week, a report was presented by the Surveyor (Mr. W. H. Mansbridge) giving a list of the electric lamps found out from the 7th to the 16th ult.—numbering in all 13. The Chairman (Mr. C. Steves) reported that the Lighting Committee were going round the district in order to see the effect of the lighting at different points where gas-lamps had been removed and no substitutes provided. A great many complaints had reached the Board of the failure of the electric light; but a far larger number of complaints had reference to the non-replacement of lights which existed when gas was used. The Committee had not yet completed their perambulations; and therefore their report was not yet complete. Mr. Samuels said the Committee were really considering how best to provide light for the places which had suffered by the change from gas to electric light. Subsequently a letter was read which had been received from the electric light contractors stating their willingness to supply and fit any additional lamps on the present contract, of 16-candle power, at £2 14s. per annum. They also offered to fit up one 2000-candle power arc lamp for the inspection of the Board, without any charge for the experiment; but for this they would prefer to wait until they had a new engine running, which would be in a few days. The Clerk said he had seen Mr. Joel since the receipt of the letter; and he was willing to put up a 300-candle power incandescent lamp free of charge, so that the Board might see the effect of larger lamps, both arc and incandescent. The Chairman observed that he had told Mr. Joel that they must certainly

have more light in some parts of the town; and that it was a question whether they should use electricity, gas, or oil. Mr. Schmidt said he was afraid that 16-candle lamps would not give satisfaction; and that they ought to have 32-candle power like those now in use. Mr. Pooley observed that he was rather inclined to try 16-candle lamps; there could not be much difference between them and what they now had as 32-candle lamps. (Laughter.) After some further remarks of a conversational nature, the matter dropped. Before the Board adjourned, a letter was read from an inhabitant in the Sebright Road, stating that since the gas-lamp was discontinued, he had to "grope his way" to his gate, and that the residents would esteem it a great boon if they could have a gas-lamp again or even an oil-lamp.

THE ELECTRIC LIGHTING EXPERIMENT AT BRADFORD.

Considerable progress is reported to have been made during the last few weeks with the experimental installation of the electric light which the Corporation of Bradford have decided to carry out. The erection of the station is being proceeded with as quickly as circumstances will permit. Workmen have been employed for some days in laying the cables along Kirkgate and some of the other thoroughfares in the centre of the town; and it is believed that the whole of the preparations will be completed before Christmas. A sum of £15,000 has been granted by the Town Council to the Gas Supply Committee to cover the cost of the installation and incidental expenses connected therewith. Should, however, the experiment be successful, and the tradesmen and others in the centre of the town show a disposition to avail themselves of the facilities offered them by the Corporation for lighting their premises by electricity, it is probable that the area of supply will be extended. The number of applications which the Committee have already received lead them to expect that such an extension will soon become necessary; and, foreseeing this contingency, they are carrying out the present works as though they were but a part of a larger scheme, which the Provisional Order obtained for the purpose authorizes them to effect. Two main cables are being laid to the Town Hall and the Free Library; and it is anticipated that both these buildings will be lighted by electricity, which will also be supplied to tradesmen and others along the streets through which the cables pass. Connecting wires, it is said, can with little difficulty and at a moderate cost, be laid under adjacent streets; so that, if need be, the whole of the centre of the business part of Bradford can be lighted by electricity during the course of a few months from the present time.

THE PROPOSED MODIFICATION OF THE THIRLMERE WATER SCHEME.

As intimated elsewhere to-day—in our "Parliamentary Intelligence"—the Corporation of Manchester intend applying to Parliament next session for permission to deviate from the Thirlmere scheme as authorized to be carried out. Alluding to this proposal, a correspondent of the *Manchester Guardian* says: "All lovers of English scenery will hear with satisfaction that the Manchester Corporation are petitioning Parliament amongst other things for leave to depart temporarily in some measure from the original design of the Thirlmere water-works undertaking. Parliamentary notice of their wish has been served; and we can hardly doubt that when the question comes on for hearing, the House will be unanimous in granting the leave that the Manchester Water-Works Committee seek. It is not only that the reduction of the scheme will entail a temporary economy, but it will also in an important degree diminish the immediate damage to the beauty of Thirlmere. There is only one Thirlmere in the world, and lovers of beautiful England will greatly rejoice at anything which shall help to preserve to us its charm even for a generation. All who knew intimately the western shore of the lake were troubled; they felt not only that those who filled the fields there, and had tilled them for generations, were to be drowned out by the projected raising of Thirlmere Lake to 50 feet above its present level, but they realized also that by the Act of Parliament a huge main road, as useless as it would be costly, was in contemplation all along above the western shore. This road in its engineering would destroy permanently two or three of the finest crags in the Western Cliffs; and its debris and embankment would be a visible scar for centuries all along the Armboth Fells, and would by its very making quite prevent people getting down to the lake shore, take from the height of the Fells, and give a long level line of ugliness to the eye. And who wanted it? It was thought the public needed it. On inquiry this was seen not to be the fact. The present road on the east was to be widened in part, if not wholly. The few farmers were content with the old packhorse road for market purposes; the ratepayers of the district knew that a great road in a rainy country takes a great deal of repairing, and rates were high enough as it was. Unless, therefore, Parliament compels the waste of the ratepayers' money, the road for the present will remain in abeyance; the level of the lake will be raised only 20 feet; and the western shore of Thirlmere will be spared. The ex-Mayor (Sir John Harwood) and his coadjutors on the Water-Works Committee deserve all credit for their prudence in this matter."

THE PROPOSED PURCHASE OF THE TONBRIDGE WATER-WORKS BY THE LOCAL BOARD.—The question of the advisability of applying to the Local Government Board for permission to borrow the necessary funds for purchasing the undertaking of the Tonbridge Water Company (reference to which was made in the *JOURNAL* last week, p. 949) was discussed at a specially convened meeting of the Local Board last Tuesday. In the end it was decided by nine votes to six, not to apply for borrowing powers; so that no further steps will be taken in the matter.

NORTHERN COAL TRADE.—The coal trade of the north has begun to display its winter characteristics. The demand for the steam coal of Northumberland has fallen off, and is likely to fall still further; and this is affecting prices, and will probably do so for some months—until there is again the summer demand. On the other hand, the inquiry for gas coal is very heavy; and the collieries find a difficulty in supplying all the orders they have—for in no previous year has the demand for gas coal been as large as it is now. Steam coal is now quoted at about 8s. 9d.; but second-class is about 6d. lower. There is a glut of small steam coal in the market; and the best kinds are quoted at 2s. 6d., though a discount is often allowed to effect a clearance. For gas coal the prices vary considerably; but about 7s. 6d. may be put as that for best qualities. The tenders for coal for the chief local railway are attracting attention—as was to be expected, when it is remembered that there is paid by this one Railway Company more than £15,000 monthly for coal for locomotive purposes alone. It is anticipated that there will be a keen competition for the contracts, and that the Northumbrian pits will endeavour to supply more; but at the same time it is expected that the price will be slightly above what it was a year ago. Household coal is dull; the season not being cold enough to develop the demand as usual. There is a large call for coal for steamship use; and fair prices are obtained. Other branches of the coal trade present little change this week.

THE DETECTION OF WATER LEAKAGE AND WASTE BY THE DEACON METER.

Our Edinburgh Correspondent in his "Notes" a few weeks since, referred to an attempt which had been made to induce the Edinburgh Water Trustees to adopt the Deacon waste-water meter. The Works Committee took the matter in hand; and, after consideration, decided, before coming to any decision, to obtain reports on the matter from their Water Engineers. In the meantime the *Scotsman* has been collecting information respecting its working from various places where the Deacon system is in operation; and last Tuesday published the first of the letters they had received in answer to their inquiries.

The first letter was from Mr. J. Hepworth, Assoc. M. Inst. C.E., the Engineer and Manager of the Carlisle Gas and Water Works. He stated that the average daily consumption of water for domestic and all other purposes in Carlisle in 1875 was 38 gallons per head of population. In that year he directed the attention of the authorities to the excessive quantity of water supplied, and the desirability of preventing waste; and for this purpose recommended the adoption of the Deacon waste-water meter. The system was not adopted until 1878, when the average daily delivery of water had reached nearly 40 gallons per head of population; and even then the system was only partially introduced. Six meters were fixed in as many districts, comprising about one-third of the entire population supplied with water. The results revealed by the waste meters, he says, were somewhat extraordinary. The average consumption of water over the whole city was known to be about 40 gallons per head; but in one of the districts supplied through a waste-water meter, it was found that the water delivered was only about 16 gallons, while in another it was nearly 60 gallons per head. This led to a thorough examination of the whole of the water mains, services, and consumers' fittings. Numerous leakages were soon discovered, localized, as they were, to some extent by the system introduced; and within a short time, the 60 gallons delivery was reduced to 20 gallons. In the first year (1878-9), after the adoption of the system, out of 8000 inspections, 232 leakages from mains and services, and 812 leakages from consumers' water-fittings—principally water-closets—being a total of 1004 leakages, were discovered and repaired. In the following year, out of 5030 inspections, only 437 defects were found to exist. The reduction in the average daily delivery of water in one year was from 40 gallons to 23.50 gallons per head, and has remained at about the latter quantity until the present time. With the view of its further reduction, the Corporation have lately resolved to extend the system over the whole city; and Mr. Hepworth is of opinion that there is no justification for a higher consumption than 20 gallons per head per day for all purposes. The cost of the system as applied in Carlisle, when complete, will be about £1000; and its annual cost is estimated at £150. The annual saving effected exceeds its total cost; the estimated cost of filtering and pumping the quantity of water previously wasted being about £1700 per annum. The letter concludes by stating that the consumers use as much water as required; and not only has the cost of filtering, pumping, and distributing water been reduced, but the supply of water has been continued with greater regularity, at a higher and more constant pressure, and at a reduced charge to all consumers.

Reports prepared by Mr. A. R. Binnie, M. Inst. C.E., the Water Engineer of the Bradford Corporation, on the working of the Deacon system in the borough in 1886 and 1888, were forwarded by Mr. O. Nicholson, the Waste-Water Engineer. An abstract of the 1888 report was published in the *JOURNAL* last week (p. 948).

Regarding the working of the system in Bolton, Mr. R. H. Swindlehurst, M. Inst. C.E., the Corporation Water Engineer, in his reply, spoke in very favourable terms. He said that they had only six Deacon meters in use at present. The saving of water in those districts where they are fixed was most satisfactory, so much so that he had recommended the Corporation to apply the system to the whole of their area of supply. He also enclosed a copy of a report prepared by himself upon the results attained with the meters; but the Water Committee, he says, have not yet passed any resolution as to its adoption or otherwise. In the course of this report Mr. Swindlehurst stated: "The daily consumption when four of the meters were first put in, stood at 464,100 gallons; now it is reduced to 258,600 gallons—showing a saving of 205,500 gallons a day. This result, although perhaps startling to the uninitiated, is but similar to what has been discovered wherever the waste-water meter system has been tried. After careful consideration, and not wishing to over-estimate the quantity I expect the saving to be effected over the whole area of supply will average five gallons per head per day. It may prove more; but I shall be very much surprised if it is less. Five gallons per head per day on 195,000 persons amounts to 975,000 gallons a day, or 355,875,000 gallons per annum, which at 4s. per 1000 gallons, the cost price of the water, equals £5981 5s. per annum, taking which to represent a return at the rate of 5 per cent., would imply a capital cost of £118,625 on works to yield that quantity."

The Secretary of the Lambeth Water Company (Mr. J. H. Louttit) supplied some interesting figures regarding the results achieved by the use of the Deacon meters in his Company's area of supply. The Lambeth Company supply an area of about 100 square miles, containing at the present time 88,097 services, 44,823 of which receive constant supply at high pressure. Of these, 38,300 houses are controlled by Deacon's waste-water meters, without the use of which, or some similar appliance, it is believed, he says, the Company would have been quite unable to extend and maintain the system of constant supply, except at a ruinous cost. The number of meters in use is 86 4-inch and 4 6-inch; and each meter supplies, on an average, about 400 houses. When Deacon's system was commenced in 1880, the average consumption per head per diem for all purposes was 34 gallons, with a population of 12,200 people under meter inspection. At the present time, it is a little above 20 gallons per head, with a population of about 308,000; and it is hoped that still better results will be obtained.

Writing of his experience with the Deacon meter at Gloucester, Mr. R. Read, Assoc. M. Inst. C.E., the City Surveyor, says that he first advised the adoption of the system in February, 1881, as an alternative to spending £10,000 for an additional and very doubtful supply of water. After two-and-a-half year's discussion, he fixed the first meter in October, 1883, and completed the whole system by May, 1884; the city being divided into twenty meter districts. The whole cost of the installation was £2000; the meters and fixing taking half the amount, and additional valves in the mains, and stop-taps to the services the remainder. Previous to October, 1883, the supply had always to be shut off at night during dry seasons, and the consumption ranged from 950,000 gallons up to 1,000,000 in frosty weather per day. By June, 1884, the consumption was reduced to 600,000 gallons per day; or, in other words, the consumption was steadily reduced from 31 gallons per head per day to 16 gallons per head per day as a minimum in 1885. Since that date it had fluctuated between 16 gallons and 17½ gallons, notwithstanding a very large increase in the number of consumers. This consumption includes about 3 gallons per head per day for trade purposes, and an unsparing supply for flushing sewers. Mr. Read's experience convinces him that, however large the supply to a community

may be, unless it is controlled by a mechanical system of inspection like Deacon's, the people will exceed the limits of supply in a very short time. As an experiment, he fixed an ordinary meter to one of the dirtiest courts in the town, and found they used or wasted 40 gallons per head per day. Another meter was fixed to a new cottage, with a man, wife, and four children living in it, doing all their own washing; and the consumption for twelve months averaged 6½ gallons per head per day.

Mr. C. Gilby, Manager of the Bath Water-Works, states that the system is now in operation in districts of Bath and the neighbourhood containing a population of about 40,000. Formerly the supply was an intermittent one—on for from two to six hours daily. The consumption was then rather over 30 gallons per head. When the constant service was first introduced under the meter system, the average daily consumption was 43·7 gallons; and it has already been reduced to 22. The trade supply, he says, is 1·2 gallons per head, and is included in the above figures.

It was reported from Clevedon that during the year before the Deacon meters were introduced, there was an average consumption of 37 gallons a head per day, of which, it is said, 25 gallons were waste. During the year following their introduction, the supply was 23 gallons a day per head, of which nearly 10 gallons are assumed to be waste.

The Water Engineer of Abergavenny (Mr. J. Haigh, Assoc. M. Inst. C.E.), after four years' experience of the system, says he cannot speak too highly in its favour. By its use, he had succeeded in reducing the waste to the extent of 16 gallons per head per day, which means an actual saving of water to the town of 128,000 gallons per day. Formerly it was found that 37 gallons per head would barely meet requirements; whereas, by reducing the waste, 21 gallons per head is ample, and it is hoped to bring the waste down so that 15 or 16 gallons will suffice.

The testimony of Mr. C. Cullum, the Manager of the Newport Corporation Water-Works, was strongly in favour of the system. Formerly the daily supply was about 35 gallons per head; and last week, with Deacon's meter in use, the consumption was only 19½ gallons per head. In one district he found, by the use of the meter, that 59 gallons of water per head were taken daily; and now the quantity is not 20 gallons.

The evidence of Mr. W. H. Wilds, the Borough Surveyor of Hertford, was likewise very favourable to the use of Deacon's meters for the detection of waste. With a population of under 8000, and an intermittent supply of twelve hours per day for five days, but six hours per day for the rest of the week, the consumption and waste ran up to 16 or 17 million gallons of water per quarter. By means of Deacon's waste detection system, he was now supplying the town on a constant service with a consumption amounting to only 6 million gallons per quarter; and he says he is confident that, would his Water Supply Committee allow him to continue the constant night inspection, he could reduce this consumption by one-half.

Mr. J. W. Richardson, the Corporation Water Engineer of Birkenhead, in his answer to the inquiries made, also bears witness to the efficacy of the Deacon meter in detecting leakage from pipes and mains underground. According to his statement, the population now supplied by the Corporation is 93,000; and the borough is divided into twenty separate districts, the supply into each of which is through one of Deacon's waste-water meters. Previous to the adoption of these meters, there was a constant and careful house-to-house inspection for the prevention of waste, and this inspection, he states, did largely prevent waste, bringing the consumption from 35 to 25 gallons per head per day. There was, however, a large waste from pipes and mains underground that was not and could not be detected by inspection alone. Hence the additional value of the Deacon meter; for a very large proportion of the underground waste does not show itself on the surface, as is generally supposed. In one case in the town, there was an underground waste, from cracked mains, of nearly a million gallons per week discovered wholly through the waste-water meters. With the aid of stop-cocks to shut off the supply to all defective fittings, and the use of the Deacon waste-water meter, the supply in Birkenhead is reduced to 15·48 gallons per head per day. In 1882, previous to the fixing of stopcocks and the Deacon waste-meters, the rate of supply was as high as 25 gallons per head per day; the reduction being 9·52 gallons. Having had every means of testing the value of the use of the Deacon waste-water meters as against close and constant inspection without them, Mr. Richardson said he had no hesitation in saying it is impossible to check waste as soon, or in the same efficient manner, by inspection without the use of the meters, as with them.

The introduction of the Deacon meter into Widnes in 1886 has, writes Mr. Isaac Carr, the Manager of the Local Board gas and water works, resulted in a saving in waste of 35 million gallons per annum. Four of the meters are used to check the supply to 3700 houses, or to a population of about 20,000. Previously the waste was not excessive; being only at the rate of 7 gallons per head of population per day. But this, by means of the meters, has been reduced to 1·5 gallon per head. The present total consumption per head per day, including the 1·5 gallon waste, is 8·5 gallons. When the system was first commenced, a number of underground leakages that must have been running for years were discovered—such as old and forgotten service-pipes with open ends into drain-pipes, &c., which, but for the meters, would in all probability have still been running. The old-fashioned mode of house-to-house inspection is, Mr. Carr thinks, almost useless for the checking or discovery of underground waste. To do this effectually, meters must be employed; and the Deacon system, he says, is the best he knows of.

Although the system has only been in use in Chester for a very brief period, Mr. J. Dugdale, the Engineer and Manager of the water-works, is able to contribute satisfactory evidence of its usefulness. Time has not permitted of a complete inspection of the city being made, so that all the defects have not been remedied. Previous to its introduction, part of the supply was obliged to be limited to sixteen hours per day on account of the great amount of waste; but this, Mr. Dugdale says, has now been altered, and the whole supply is on constantly, and less water is delivered than before. This statement is verified by the following comparative table (which was given at the end of Mr. Dugdale's letter) showing the number of gallons of water consumed each day during the weeks ending Nov. 25, 1888 and 1887.

	1888.	1887.
Gallons.	Gallons.	Gallons.
Nov. 19	1,248,958	1,874,800
" 20	1,231,888	1,664,600
" 21	1,231,888	1,698,200
" 22	1,218,084	1,798,400
" 23	1,241,170	1,807,600
" 24	1,268,778	1,633,400
" 25	1,116,458	1,764,600

Judging from the diagrams and his past experience, Mr. Dugdale anticipates a much greater reduction than is shown in these figures.

Southampton, it appears from a letter sent by Mr. W. Matthews, the Engineer of the water-works, has likewise considerably benefited by the use of Deacon's meters. He states that the system was got into work about the middle of 1885. The meters, 22 in number, with the necessary fittings, cost £1340. In addition to this they had outside stopcocks fixed to about 2500 houses, where they were not already existing, at a further

cost of £1250. Prior to 1885 the consumption of water in the borough had been 61 gallons per head. Within a few months of setting the system to work, they were able to absolutely close one of the old pumping stations; effecting an immediate saving of about £700 per year. The consumption has now been reduced to 31 gallons per head, including that used for manufacturing purposes, which is at the rate of 200,000 gallons per day. Previous to 1885 Mr. Matthews says they were pumping 3½ million gallons per day, compared with 2 millions now; and he hopes to further reduce the consumption to 15 gallons per head, which, he considers, is ample, including what is necessary for trade purposes. The greatest waste in the borough was due to old and defective mains; and this system had enabled them to pick out districts, streets, and places where great waste was going on.

EDINBURGH CORPORATION WATER TRUST. PROPOSED ADDITIONAL SUPPLIES.

Under a remit from the Edinburgh and District Water Trustees, the Engineers of the Trust, accompanied by the Conveners of the Works and Finance Committees (Baillie Archibald and Mr. Colston), ex-Provost Wood, of Portobello, and the Treasurer (Mr. Oliver), visited the district of the Manor, the Talla, and the head waters of the Tweed on the 23rd and 24th ult., in connection with suggestions for augmenting the city supply from these localities. On the last occasion on which samples were taken of the waters of the Manor and Talla, the streams were at their minimum flow; and the water was remarkably pure. As the supply from these districts would consist to a large extent of impounded water, it was considered necessary, in order to arrive at a satisfactory conclusion as to the quality of the water, to see the streams in full flow. The party first visited the Manor on Friday (the 23rd ult.), when they found an immense volume of water flowing, of remarkable purity, and containing no apparent tinge of peat. The next day they visited the Talla and Fruid, and the high waters of the Tweed. On arriving at the point where the Talla flows into the Tweed, it was observed that, while the Tweed itself was considerably discoloured and turbid, the water from the Talla was so pure and of such abundance as to make a decided difference on the Tweed for fully a mile of its course. The same effect was observed at the junction of the Manor and the Tweed. A visit was next paid to the Fruid tributary; and there, as at Talla, a very large supply of comparatively pure water was flowing. The Manor scheme is estimated to afford a supply of 15 million gallons per day, after making full provision for compensation. It might be brought in in two sections—the first of ten million gallons, and the second of five million gallons. The water from the Talla might be brought in either separately or in conjunction with the Fruid water. If the first course is adopted, about 7½ million gallons of water may be obtained; and if both waters were united, and compensation given by the construction of a large reservoir in the Tweed, it is computed that a supply of 20 million gallons may be procured. The Manor scheme involves, it is understood, a tunnel of about 5 miles in length between the valley of the Tweed and the Leadburn ridge. The distance from Edinburgh is about 27 miles, and that of the Talla and Fruid about 37 miles; the latter scheme also involving some tunnelling. The sites for the reservoirs, particularly those for the Manor and Talla, were considered excellent. In a short time the Engineers will be able to present a report to the Trustees, as to the cost of the various schemes, including that of St. Mary's Loch; stating the quantities and qualities of the water which may be obtained from each.

LIVERPOOL CORPORATION WATER SUPPLY. PROGRESS OF THE VYRNYWY WORKS.

Tuesday last—says the *Shrewsbury Chronicle*—will long be remembered in the Llanwdddy district as the day on which two most important events connected with the history of the Liverpool Water-Works took place. In the first place, the construction of the Vyrnywy reservoir has so far approached completion that Mr. G. F. Deacon, M. Inst. C.E., the Engineer, commenced to close the valves of the discharge-pipes passing through the fine dam of masonry, with a view of commencing to impound the waters and to fill the large artificial lake, which before next summer will supply the city of Liverpool and other communities on its route with water. Though no impounding had been done up to that date, the recent rainfall has been so heavy that the water behind the masonry dam extended two miles up the valley; but now the lake will rapidly increase in depth and area. The whole of the water flowing down this valley will be intercepted until that is accomplished. Nearly all the buildings of the village of Llanwdddy and elsewhere are pulled down; and the last inhabitants will soon vacate the bed of the new lake about to be formed in Wales. Though often stated, the magnitude of this undertaking does not appear to be generally understood. Lake Vyrnywy will be nearly five miles long, and will be at once the largest and most picturesque lake in Wales. The masonry dam and the arches of the viaduct carrying the road over it have been completed; while the last work in connection with the parapet, at a height of 161 feet above the foundations, is in progress. The straining tower—in which necessary means are provided for drawing off water at any required level, and within which suspended peaty and other impurities will be arrested—is a considerable height above the overflow level, and will form one of the most striking and picturesque features in the lake. The filter-beds and intermediate reservoir near Oswestry are fast approaching completion.

WORCESTER CORPORATION WATER SUPPLY.

At the Meeting of the Worcester Town Council to be held next Tuesday, the Water and Sewerage Committee will present a report on the water supply of the city. They state that if the present source of supply is to be retained, it appears necessary to carry out the works referred to by Mr. Purohas (see below) at an estimated cost of £26,000. They would, however, prefer obtaining a substituted supply from Burcot, if it could be had at a reasonable cost; but they regard the price asked by the East Worcestershire Water-Works Company for the Burcot Wells as prohibitive. Failing the latter supply, they say it is desirable to sink a trial bore-hole at the site near Aston Fields, referred to in Mr. Etheridge's report of Jan. 16, 1885*, with a view of testing the opinions of the experts that by sinking to a lower level than the present Charford bore-hole, water would be obtained from the underlying Bunter sandstones of a similar quality to the Burcot water. The Committee recommend that they be authorized to take the necessary steps for sinking a trial bore-hole near Aston Fields, and to obtain the necessary surveys for the purpose of ascertaining the probable cost of bringing water from Aston Fields to the city. The works estimated for by the Surveyor (Mr. Purchas) are as follows: New subsiding tanks, to hold 2½ million gallons, including land about 2½ acres, at 2s. per yard, £6270; new filtering-beds, capable of filtering about 3 million gallons per day, £380; new reservoir, to hold 2½ million gallons, including pipes and valves, £18,000; covering pure water-tank, £850—making a total cost of £26,000.

* See JOURNAL, Vol. XLV., p. 309.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

The Edinburgh and Leith Gas Commissioners held a meeting last Monday, at which they transacted a large amount of business. A report is given in another column.

The proposal by the St. Andrews Town Council, to take over the local Gas Company's undertaking, has been shelved for another year. At a meeting of the Council on Tuesday, Provost Paterson said that some scruples had arisen as to the reading of the Burghs Gas Supply (Scotland) Act; certain members thinking that if they were to confirm a previous resolution in favour of the transfer they would be bound to go on with it immediately. In deference, he said, to these scruples, and the desire of the electors for further information, he moved the following resolution:—"That this meeting be adjourned to a date not later than the last Tuesday of September, 1889, with power to the Provost to advance such meeting on the requisite notice, and that, failing other instructions, the Clerk be instructed to call an adjourned meeting for the above date, and also to address a letter to the St. Andrews Gas Company in the last week of July, 1889, requesting them to convene a special meeting of their shareholders for the same date as their annual meeting, to consider whether they will make an offer to the town of their property for £13,250." In support of his motion, the Provost said he could now show his hand. Under the Act of 1870, the Gas Company might have applied for a Provisional Order, giving them the control of the streets, which, as a private Company, they had not at present. They could not now do that. Had the Company obtained an Order, the Town Council would not have had the same power in the taking over of the gas-works. He did not want to approach the Gas Company at present. An unfair dividend, he said, was declared last year; but in May the books of the Company would be before the shareholders, and the Council would then be able to value the Company's property at a more correct figure. The present prosperity of the Company was, he considered, a bogus one. The motion was adopted. I may point out that the dividends paid by the Company have been: In 1881-2, 30s. per share, with 10s. bonus; in 1882-3, 40s.; in 1883-4, 40s.; in 1884-5, 40s.; in 1885-6, 40s.; in 1886-7, 30s.; and in 1887-8, 50s. This so far bears out the Provost's notion that an inflated dividend was paid on the prospect of the purchase of the undertaking by the Corporation.

Mr. Adam Pratt has not resigned the chairmanship of the Aberdeen Gas agitation on his appointment to the membership of the Gas Committee of the Town Council. The Sub-Committee, consisting of Mr. Collie, the Convener of the Gas Committee, and two other gentlemen, met on Tuesday to consider the cases of alleged overcharge, which, through the instrumentality of Mr. Pratt before his election to the Town Council, had been submitted to them. The Sub-Committee drew up a report, which set forth that, in their opinion, there was no ground for the complaints made. By Dr. Wallace's report it was shown that the quality of the coals used at the works was satisfactory. A list containing 134 complaints of increases was before the Sub-Committee; but this number was reduced to 84, and, even in these instances, the increases were accounted for, among other reasons, by the construction of larger mains. In certain districts from which complaints came, it was found that, while there were some small increases, the decreases were of a substantial character. The Gas Committee met on Wednesday, and received the Sub-Committee's report. Mr. Pratt took exception to the finding of the Sub-Committee, and protested against their conclusions; reserving his views on the matter until the public meeting of the Council. He urged that it was impossible to deal with so large a subject in detail until the report was submitted in print to the members of the Committee. It was therefore agreed to print the report, to circulate it among the members, and to discuss it a month hence.

A case of suffocation by gas at Aberdeen has this week terminated fatally. On Friday of last week, a young woman, from the country, entered upon her duties as domestic servant in a house in the west end of the city. Knowing nothing of gas, she blew the light out on going to bed; and in the morning was found by her mistress lying in a state of unconsciousness—the room at the same time being filled with gas. She was sent to the Royal Infirmary, where she died last Thursday.

An anonymous writer, under the name of "Scrutiniser," seems resolved on giving as much trouble as possible to the Dundee Gas Commissioners. It was he who took up, and has made his own, the question involved in the mixing of air with gas to assist in oxide purification, to which I have made reference on previous occasions. To most minds, Mr. McCrae's report on the subject disposed of it; but "Scrutiniser" is still unconvinced. In a letter to the local press on Thursday, he returns to the charge, taking for his text the published statistics, which show that 10,000 cubic feet of gas were derived per ton of coal carbonized. The published accounts, he says, show that as low as 7000 cubic feet of gas per ton are produced from a large quantity of the coal used; and he comes to the following conclusion:—"There are two strong and tempting reasons, from the Gas Manager's point of view, for the absorption of air; but we are only told of one—viz., the saving of labour and expense in the process of purification. There is another reason, not less potent. It is a cheap way of very materially assisting to swell the total make of gas and cover the very great waste and loss of gas which have taken place at the very commencement of its manufacture within these works for a very considerable time. Why should the consumer have to buy and pay for the free air of heaven at the rate of 3s. 8d. per 1000 cubic feet?" To this I would say that as long as the Commissioners supply gas of the requisite illuminating power—and that is not yet questioned—it is difficult to conceive what prejudice can be done to the consumer.

A strange question has arisen in connection with the administration of the new Falkirk and District Water Act. The measure was carried through the Houses in the face of strong opposition by the Carron Iron Company. After it passed, the Trust was constituted, and they laid an assessment. The Carron Company refuse to pay this assessment, on the ground that clause 71 of the Act provides that occupiers shall not be liable to pay the domestic rate "unless some pipe of the Trustees shall be laid down within 100 feet of the outer wall, fence, or boundary" of their property. It is likely that the opinion of Counsel will be taken on the question; and it may have to be fought out in the Law Courts.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

The office of Gas Analyst to the City of Glasgow, rendered vacant by the death of Dr. William Wallace, is to be continued in accordance with resolutions recently come to both by the Magistrates' Committee and by the Committee on Gas Supply; and the intention, I believe, is that the appointment will be made on the understanding, if not by express stipulation, that the successor to Dr. Wallace will have the same work to do, and receive the same salary as he had. If I mistake not, the salary has for some years been £200 per annum, for which an examination of the gas made at the tree works owned by the Gas Trust must be carried out and reported on every week. I cannot say yet how many candidates there are in, or are likely to enter, the field for the vacant office; but I

know that one of them is Mr. R. R. Tatlock, F.R.S.Edin., F.C.S., &c., who has been one of the public analysts for the City of Glasgow during at least fourteen years, and for some five or six other burghs during various periods of time. Mr. Tatlock was partner with Dr. Wallace till within a few weeks of his death. In his application for the appointment, he does not publish any testimonials, considering that his qualifications for such an office are sufficiently well known to render them totally unnecessary. Mr. Tatlock is also candidate for the similar office at Paisley, which was also held by Dr. Wallace.

Some time ago I mentioned that Bailie (now ex-Bailie) Shearer, a prominent member of the Glasgow Gas Trust, had given notice that he would ask for a vote of £5000 from the annual gas surplus to be devoted to the purposes of the "Common Good." In course of time, the Gas Committee so framed their accounts, by "writing-off" here and "writing-off" there that the actual surplus for the last financial year was reduced to less than £2400, but which, with the balance carried over for the preceding year, made a total of £5200. So far as I remember, Bailie Shearer never returned to the matter at any meeting of the Council; and a feeling generally prevailed that the proposal had been permanently put on the "shelf." It now seems, however, that it has been taken down from the resting-place, a member of the Gas Committee, I am informed, having moved his colleagues, or a majority of them, in favour of recommending to the Council sitting as the Gas Trust, to vote a large proportion of the surplus—£3000 it is said—for public purposes. The consideration of the motion will come before the Council at the monthly meeting on Thursday next, on which occasion some stiff opposition is likely to be offered to the proposal by those Gas Commissioners who believe in the propriety of all gas surpluses being devoted to the legitimate purpose of reducing the price of gas to the consumers. There are, I am glad to say, still some persons who hold, as an article of faith and as an item of common-sense philosophy, the principle that "every herring should hang by its own tail," and that every municipal trust should deal exclusively with its own "ways and means." We shall see how members of the Council rise to the circumstances of the occasion. Within my recollection, the surplus funds of the Gas Trust have only been dipped into twice—possibly three times.

The Kilsyth Gas Commissioners, on the motion of ex-Provost Whyte, have resolved that in future no deposits be asked from gas consumers as security for the payment of their accounts. In some cases the deposit has been 2s. 6d.; and in others, 5s. They have also decided that all deposits in the possession of the Gas Trust be returned to those persons from whom they were exacted. It is confidently believed that the abolition of the "security" deposit will induce many persons to become gas consumers who have hitherto regarded the deposit as a stumbling-block, and as an unwarrantable impost.

By the way, this bit of news from Kilsyth reminds me that the Partick, Hillhead, and Maryhill Gas Company have just been taken to task by a correspondent in one of the local papers for what he calls a gross injustice—viz., the exacting of deposits of money as security by the Company, and of claiming the right to cut off the gas supply from any person who refuses to pay the deposit. He asks if the Company have not the same means of recovering debts as others, and urges that it would be time enough to cut off the gas supply when there were arrears due. Then he proceeds to remark that it is clear to anyone that the Company derive the benefit of the interest on a very large sum of money for which no return is given, and on money which does not belong to them.

In the early part of the week, the Glasgow pig-iron warrant market was inactive; but during the latter half of the week it rallied, and became more satisfactory than it has been for some time. Several influences have been at work; one of them being a growing disposition to limit the production, due to the cost of making it, and to the possibility of loss in disposing of the iron. The closing price for Scotch iron yesterday was 9d. per ton better than at the close on Friday last week. The top price reached was 42s. 0½d. per ton cash.

The coal trade is still a little slack in the shipping department on account of the slow arrival of steamers. Still, many firms are doing a fair business; and there are numerous vessels awaiting cargoes. Contracts for next year are now being talked of, and will shortly require to be arranged. Shippers are expecting rather better rates than during the present year. For months past they have been sending away large quantities of coals under contract at prices very much below those current in the open market; and, at the same time, advanced rates of freight have had to be found. On the whole, therefore, this part of the trade cannot have been very profitable. On the larger contracts a rise of at least 1½d. a ton is being spoken of for deliveries over the whole of next year; and this advance appears small, and would seem to indicate that the present high quotations of coals are not expected to be of very long continuance. Meantime the f.o.b. prices are maintained; being indeed in most cases a shade higher than they were a week ago.

DANGEROUS OILS.—At the Court of Aldermen, held at the Guildhall, last Tuesday—permission having been granted in several cases to store petroleum under certain regulations—the Lord Mayor stated that, after the terrible explosion at Calais, there was a feeling of insecurity in London—a feeling of alarm, he might say—lest they should be subjected to a similar calamity in the City. He had ascertained at the Thames Conservancy Board facts which he thought it would be very gratifying to the public to know. First, no volatile oil of any kind was allowed to be unshipped, if he might say so, westward of Thames Haven. Then no oil of the same quality was imported into this country at all. It seemed that the duty on oils of that character going into France was a very high one; and therefore only oils of a very low quality were imported there, while the best oils of that description were alone imported into England. His Lordship thought it desirable these facts should be made known to the public; so that the alarm felt might be at once quelled.

THE SWANSEA CORPORATION WATER COMPENSATION CASES.—The question of the costs involved in the action *Lewis and others v. The Corporation of Swansea* (argued last July before the Court of Appeal, as reported in the JOURNAL at the time) was mentioned in the High Court recently by Mr. Finlay, Q.C., for the Corporation. It may be remembered that the plaintiffs, who are manufacturers, brought an action to recover penalties from the Corporation of Swansea for having withdrawn a certain water supply from their works, &c. The result was that both parties were partially successful; but no costs were allowed to the defendants in respect to the points on which the plaintiffs had failed. The defendants raised no objection to the plaintiffs receiving the costs of the matters on which they had succeeded; but Mr. Finlay submitted that the order as to costs made on the last occasion should be varied so as to give the defendants a portion of the costs. Mr. McIntyre, Q.C., opposed the application. The Master of the Rolls, after consulting with his colleagues, said the order as to costs would be in this form—the plaintiffs to have costs of the action and trial before Mr. Justice Denman, and defendants to have costs of the issues, if any, found for them; and as to the present application, there would be no order as to costs.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Dec. 1.

Sulphate of Ammonia.—The improvement in the market has been rudely checked by a sudden change in the tendency of nitrate, as well as by the unexpected veering round of the principal operators in sulphate, who are now sellers at below the prices they were willing to pay a week ago. This metamorphosis makes one feel less secure about the future; for if the recent improvement in both commodities rests on substantial grounds, there is no occasion to lose heart at a critical moment, and without any sufficient reason. Almost the only danger appears to lie in the fact that large quantities of both sulphate and nitrate are in second hands; and that there exists a great desire to realize the good profits which present values still offer. The weaker nitrate market has, of course, caused the demand from sulphate buyers to fall away. The latter already see in the not-too-far-distant future the more tempting prices of a month ago return; and they will probably wait for a favorable opportunity for their purchases. There is, however, meanwhile no sulphate pressing on the market; and any possible depression seems to rest, to a great extent, with the makers in their manner of disposal of ready parcels. A very large production has, of course, to be got through this month; but, perhaps, in view of the present position, makers will not persist in pursuing their usual plan of clearing out their stocks before the end of the year. The closing quotations are: £12 10s., Hull and Leith; £12 7s. 6d., Liverpool. It is stated that nitrate will not fall much in price, owing to the bulk of it being held in strong hands; but, meanwhile, spot values have declined to 11s. 1½d., and there is great weakness apparent, both for present and spring delivery.

LONDON, Dec. 1.

Tar Products.—This market is now feeling the effects of a larger production; and some of the principal products are decidedly weaker, both in demand and price. This applies specially to benzole, pitch, and anthracene. Tar oils continue in good request; and for the first time for many years past at this season are somewhat scarce. Naphthalene continues unsaleable; and it is surprising that some ingenious inventor has not discovered a mode of utilizing this product for illuminating purposes—especially remembering that, at present, it has only a nominal value. The following prices have ruled during the week:—Tar, according to position, 18s. to 23s. per ton. Benzole, 90 per cent., 3s. (nominal) per gallon; 50 per cent., 2s. 4½d. Toluol, 1s. 6d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 2d. per gallon. Light oil, 3d. per gallon. Cresote, 2½d. per gallon. Pitch, 18s. to 20s. per ton. Carbolic acid (crude), 3s. 10d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4½d. per unit; "B" quality, 1s. 2½d.

Ammonia Products.—There has been unusual excitement in the sulphate market; but the week closes with this article flat. Whether this is the result of the unexpected and rapid rise in price, or the reflection of weakness in the nitrate market, remains to be seen. The price of sulphate has averaged during the week between £12 15s. and £13 per ton; but the latter figure more nearly represents to-day's value. Prices of other products may be taken as follows:—Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £25. Sal-ammoniac, £30 per ton.

[From the *Chemical Trades Journal*, Dec. 1.]

Tar Products.—The benzol market is not so firm as it was a week ago; and to-day's prices may be stated as 3s. 1d. to 3s. 2d. for 90's, and 2s. 5d. to 2s. 6d. for 50/90's. The winter production is now preparing for the market; and the influx of larger supplies must have a telling effect in the course of time. The demand for solvent naphtha still continues good; and cresote is moving off as fast as it is produced. Crude carbolic acid is still firm at old rates, while anthracene, good 30 per cent., "B," is decidedly firmer at 1s. 3½d. The pitch market is still in good trim; and while 17s. 6d. is being paid in Liverpool and 18s. 6d. in London, the Yorkshire makers have realized as much as 20s. f.o.b.

Sulphate of Ammonia.—The sulphate of ammonia market is just now in a critical condition. The advance in price has stopped; and a slight relapse set in; so that, while £12 16s. 3d. was easily obtainable at Hull on Monday, not more than £12 12s. 6d. was able to be secured yesterday. Still, there should be no fear of any serious fall if makers remain cool, and do not attempt to press business in a falling market; stocks are low and there is not much offering, and makers as a rule are fairly well sold. We have only to reiterate the caution contained in our market report of Nov. 3, "Makers should be mindful that the act of running up the price to-day may leave them short of customers for to-morrow." Everyone cannot expect to realize the top prices; and it is only when a constant business is being done that the market can be declared healthy. To-day's prices are: Hull, £12 12s. 6d. to £12 15s.; Leith, £12 13s. 9d.; London and Beckton, £12 15s.

THE RIVER LEA AND THE SEWAGE OF TOTTENHAM.—At the meeting of the Hackney District Board of Works last Wednesday, Mr. Cox stated that the Metropolitan Board of Works had decided to grant the request of the Board to an extension of the privilege provided by the Lea Purification Act for the flowing of the Tottenham effluent into the main sewers of the Metropolis. The privilege under the Act would expire next June. He thought the Board should not rest satisfied with having obtained this extension, and allow themselves to be face to face with a similar state of things next year. He had been making inquiries; and he said most unhesitatingly that the effect upon the Metropolitan sewers was comparatively nil. He advised the Board not to go to sleep, but impress the matter early upon the attention of the new County Council, with a view to getting that body to grant a further concession.

SALFORD CORPORATION GAS AFFAIRS.—The Salford Gas Committee had under consideration, last Thursday evening, the question of admitting reporters to their meetings, which was referred to them by the Town Council the week before. The result was that three voted for the admission of the press and eight against. The Committee have been investigating a number of complaints respecting the demand of the collectors for deposits of money from old customers for the continuance of the gas supply. Instructions have been given that the indiscretion must not be continued. The new Gas Committee, in their endeavour to stimulate the consumption of gas, have abolished the old meter deposit, and only demand deposits from new consumers. During the last fortnight, tests have been made with a view to determining whether the gas maintains at a distance the illuminating power which it shows at the works. Tests have been made simultaneously at Eccles, the Broughton Town Hall, and the Salford works, with the best available instruments, with the gratifying result that the illuminating power is shown to be fully maintained at these places at 19-candle power. The tests are to be continued.

SOUTH AMERICAN WATER-WORKS SCHEMES.—In reference to the two water-works undertakings in South America, the shares of which have recently been offered in England to the investing public, it is reported that letters of allotment have been posted to applicants for the 13,350 shares of the Monte Video Water-Works Company; also that heavy contracts for lead and iron piping and other materials have been given out by Messrs. Baring Bros. and Co., in connection with the Buenos Ayres Water-Works scheme.

LECTURES ON COAL GAS AT BRISTOL.—The first of a series of lectures on coal gas was given last Tuesday evening, in the hall of the Merchant Venturers' School, Bristol, by Mr. Coomber. The lecturer explained, by the aid of diagrams, the various processes employed in the production and purification of coal gas, the properties of the impurities, and the effects which would be produced by them if not removed before the gas was supplied to the public. He intimated that Dr. Cook would give the second lecture on coal gas as a source of heat and light; and Mr. Munro the third, on coal gas as a source of energy in the gas-engine.

AN ARTESIAN WELL AT ALTRINCHAM.—The existence of water under Altrincham in sufficient quantity to be of practical value has at last been proved by the sinking of an artesian well at the "Royal" brewery of Messrs. Richardson and Goodall. Mr. E. Timmins, of the Bridgewater Foundry, Runcorn, sank the well; and it appears that it is capable of yielding more than two million gallons per week. The analysis is as follows:—Total solid matter per gallon at 212 feet, 31·60 grains; combined chlorine, 2·0; as common salt, 3·29; total hardness, 12°; sulphate of lime, 10·37 grains. The analyst remarks: "The water is of very good quality for a first sample, and bids fair to be a very first-class water. The residue is principally of calcareous salts."

THE PROPOSED ELECTRIC LIGHTING OF THE CITY.—At a meeting of the Court of Common Council last Thursday, the Chairman of the Commissioners of Sewers (Mr. W. H. Pannell) was questioned as to what progress had been made with the arrangements to supply the City with electric lighting; and, in reply, he said the matter had been referred to the Streets Committee, with instructions to take the advice of Mr. Preece. They had had printed reports from this gentleman and the Engineer to the Commission; and the Committee had proceeded so far satisfactorily that they had now virtually agreed upon the lines on which tenders should be invited. Every substantial electric lighting company would be invited to tender; but he could hardly say at present when the tenders would be solicited.

ELECTRIC LIGHTING AT IPSWICH.—Messrs. Lawrence, Paris, and Scott, the electricians, who are desirous of supplying electricity for lighting purposes in Ipswich, are, it appears from a communication read at the meeting of the Ipswich Paving and Lighting Committee last Friday, experiencing a little difficulty in regard to the laying of their wires. In the letter they stated that after they had made considerable progress in their arrangements for placing electric wires underground, they had been disappointed to learn that the Committee were legally advised they had no power to grant permission. They, however, were not to be deterred by this, and asked to be allowed to carry wires overhead, and also for the sanction of the Committee to apply to the Board of Trade for a Licence or Provisional Order to make overhead communication. After a little discussion, the Committee adopted a resolution, on the suggestion of the Town Clerk, granting their assent for overhead wires for a limited time, and urging Messrs. Lawrence and Co. in the meantime to adopt every means to obtain powers for placing their wires underground.

GRAND JUNCTION WATER COMPANY.—The report of the Directors of this Company for the half year ending Sept. 30 last states that, owing to the prevalence of wet and cold weather during the past summer months, there was a diminution in the quantity of water supplied for road watering, public baths, flushing sewers, and other purposes; and although the domestic supplies had somewhat augmented, there was a net reduction in the water-rental, as compared with the previous half year, of £1266. The expenditure compares favourably with the figures in the last account, as well as with those of the corresponding period of 1887; and the balance of undivided profit, after payment of the dividend, will show an increase over that of the preceding half year. The Directors recommend that a dividend at the rate of 9 per cent. per annum upon the ordinary share capital of the Company, and of 7½ per cent. per annum on the £25 "C" shares, and of 7 per cent. per annum on the new ordinary £50 shares, together with interest in accordance with the conditions of sale on payments on the shares issued in February, 1883, be now declared, and that warrants be issued for the payment of the same on Jan. 15 next.

THE COWPEN LOCAL BOARD AND ELECTRIC LIGHTING.—The public lighting question at Cowpen (to which extended reference was made in the *JOURNAL* last week) was again under discussion at a special meeting of the Local Board last Thursday. A letter was read from the representative of Messrs. Nicholson and Jennings, with whom, it may be remembered, negotiations have been proceeding in regard to the proposed introduction of electric light into the town. The communication stated that the writer's principals had carefully considered the Board's offer, but they were compelled to decline the contract for any sum than £600 per lighting season. In arriving at this conclusion they had taken all the surrounding circumstances into consideration, and to accept a less sum would mean a positive loss to them. They felt great regret at having to arrive at this determination, being really anxious to obtain the contract for lighting the township; and the writer trusted the Board would still see their way to agree to the terms offered—viz., £600 per lighting season for a term of five years without discount, or for six years with discount. In the course of the discussion which followed the reading of the letter, a motion was made that the tender be accepted; but on being put to the vote, only two members were in favour of it, and four against it.

LOCAL GOVERNMENT BOARD INQUIRY AT EPSOM.—Mr. S. J. Smith, one of the Local Government Board Inspectors, recently held an inquiry into an application by the Local Board to borrow the sum of £3400 for purposes of sewerage and water supply. Mr. White, Clerk to the Local Board, opened the proceedings by stating for what purposes the money was required, and said the Board would endeavour to find water in order to prevent any anticipated water famine, as was feared would happen last year. They proposed to sink a shaft in the neighbourhood of the present works, and to carry out a more efficient system of distributing the water. After some considerable amount of discussion as to the advisability of carrying out the plan proposed—one feature of which was to sink an 18-inch bore-hole to the depth of 200 feet at a cost of £450—the Inspector remarked that the Board had better obtain definite information as to the quality and quantity of the water they proposed to obtain before the whole loan was asked for machinery, &c.; and this it was understood was the course the Board would pursue. The Inspector expressed surprise that the present 6-inch main was both the "rising" main and the distributing main as well; and he said the Board would need to have a new rising main 1½ miles long to the reservoir, and make the old main the distributing main.

BRIGHOUSE WATER SUPPLY.—At the meeting of the Brighthouse Local Board last Friday, the Clerk was instructed to apply to the Halifax Corporation for a supply of water during the ensuing year; the maximum quantity not to exceed 360,000 gallons per diem, and the minimum 120,000 gallons.

THE PUBLIC LIGHTING OF UXBRIDGE.—The idea of resorting to oil-lamps for the lighting of the streets in Uxbridge (to which allusion has previously been made in the JOURNAL) has been abandoned; and the trial lamp which was erected by Messrs. Defries & Co. is to be removed, and gas re-instated.

THE NELSON WATER SUPPLY.—The Water Committee of the Nelson Local Board have given instructions to Mr. J. Newton, M. Inst. C.E., of Manchester, to prepare plans for a new reservoir at Ogden Clough, near Reedley. This step has been taken by the Local Board in consequence of the action of the riparian owners demanding an exorbitant compensation price for the water, and under the provisions of the recently obtained local Act.

AN INTERESTING CASE TO CONTRACTORS.—At the Brentford Police Court last Thursday, Messrs. J. Aird and Sons, of Lambeth, Contractors, were ordered to pay £353 to the Brentford Local Board, by whom they had been summoned for payment of extraordinary expenses incurred by that body in making up and repairing Gunnersbury Lane, damaged by the unusual traffic caused by the cartage of the defendants' materials to the Grand Junction Water Company's new reservoir at Ealing.

THE WATER SUPPLY OF OULTON AND WOODLESFORD.—For the better service of water to Oulton and Woodlesford, which villages are at present inadequately supplied with water by a pipe leading from the main of the Leeds Corporation at Thwaite Gate, it has been proposed by the Rural Sanitary Authority to construct a service reservoir with a capacity of 212,000 gallons. The estimated cost is from £2000 to £2500; and Messrs. Filliter and Rofe, of Leeds, are the contractors. Before the consent of the Local Government Board is given to the borrowing of a loan for this purpose, an inquiry is to be held.

BASINGSTOCKE WATER SUPPLY.—An application having been made by the Basingstocke Urban Sanitary Authority to the Local Government Board for their sanction to borrow the sum of £2000 for the purpose of extending the water-mains, and putting down more hydrants, a public inquiry was held on Wednesday last by Mr. Thornhill Harrison, C.E., one of the Local Government Board Inspectors. The Town Clerk (Mr. W. H. Bayley) having stated the requirements of the Council, evidence was given as to the necessity for an increase in the water-mains, and in the number of hydrants. The Inspector promised to lay the result of this inquiry before the Local Government Board.

SALES OF SHARES.—At the Auction Mart, Tokenhouse Yard, last Wednesday, Messrs. Edwin Fox and Bousfield disposed of fourteen £100 new shares in the *New River Company*. The prices realized were as follows:—Four shares sold at £358 each; six, for £357; and four, for £356.—Seventy £10 fully paid-up shares in the *Horneastle Water Company* were recently sold at an average price of £10 12s. 6d. each.—The following prices have lately been realized for stock in the *Tonbridge Gas Company*:—£200 of original stock, bearing interest at 10 per cent. per annum, sold for £424; £100, for £214; and £60, for £126. £62 10s. of additional stock, on which the interest is 7 per cent. per annum, secured £91; £50 of capitalized stock, carrying 5 per cent. interest, £56; and £47 10s. of ditto, £54.

UNLAWFULLY CONNECTING A WATER-PIPE.—At the Watford Petty Sessions last Tuesday, William Saunders, of Villiers Road, New Bushey, was charged with unlawfully connecting a water-pipe with the service of the adjoining premises without the consent of the Colne Valley Water Company. It appeared that the defendant was the owner of two houses adjoining each other, one of which he occupied himself, and the other he let. He had not had the water supplied in respect of the house occupied by himself; but some time ago it was discovered that a service-pipe had been connected with the service-pipe which supplied his tenant's house, and run through the wall separating the two properties. In defence Saunders stated that, after the connection was made, he had intended seeing the Water Company about it; and he added that the water had never been used. Looking at the circumstances of the case, the Bench decided to fine the defendant only 10s., and costs 16s.

Specification, quantities, and form of tender can be obtained upon application to the Engineer. Tenders, addressed to Mr. Councilor Lennard, Chairman, and endorsed "Tender for Retorts, &c.," will be delivered at these Offices not later than Eleven o'clock a.m. on Saturday, Dec. 8 prox.

The Committee do not bind themselves to accept the lowest or any tender.

ALFRED COLSON, C.E.,
Engineer and Manager.
Gas Offices, Millstone Lane,
Leicester, Nov. 10, 1888.

SOUTHWARK AND VAUXHALL WATER COMPANY.

TO COAL MERCHANTS.

THE Directors invite Tenders for the supply, at their several Stations, of about 20,000 tons (more or less) of COAL during the year 1889.

Specification and form of tender may be obtained at the Office of the Engineer, upon payment of 10s. 6d.; and the same must be sent in not later than the 10th of December, 1888, addressed to the Chairman, Southwark and Vauxhall Water Company, Sumner Street, Southwark, S.E., endorsed "Tender for Coal."

The Directors do not bind themselves to accept the lowest or any tender.

68, Sumner Street, Southwark, S.E.,
Nov. 29, 1888.

SOUTHWARK AND VAUXHALL WATER COMPANY.

TO PIPE FOUNDERS.

THE Directors are prepared to receive TENDERS from Manufacturers willing to supply

Cast-Iron WATER-MAINS and SPECIAL CASTINGS required by the Company.

Specification and form of tender may be obtained at the Office of the Engineer, upon payment of 10s. 6d.; and the same must be sent in not later than the 10th of December, 1888, addressed to the Chairman, Southwark and Vauxhall Water Company, Sumner Street, Southwark, S.E., endorsed "Tender for Pipes."

The Directors do not bind themselves to accept the lowest or any tender.

68, Sumner Street, Southwark, S.E.,
Nov. 29, 1888.

SOUTHWARK AND VAUXHALL WATER COMPANY.

TO ENGINEERS.

THE Directors are prepared to receive TENDERS from Manufacturers willing to supply

SCREW COCKS required by the Company.

Specification and form of tender may be obtained at the Office of the Engineer, upon payment of 10s. 6d.; and the same must be sent in not later than the 10th of December, 1888, addressed to the Chairman, Southwark and Vauxhall Water Company, Sumner Street, Southwark, S.E., endorsed "Tender for Screw Cocks."

The Directors do not bind themselves to accept the lowest or any tender.

68, Sumner Street, Southwark, S.E.,
Nov. 29, 1888.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

JOHN RILEY & SONS, Chemical Manu- facturers, Hapton, near Accrington, are MAKERS of SULPHURIC ACID, from Brimstone, for Sulphate of Ammonia making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitrol. References given to Gas Companies.

SULPHURIC ACID.

TENDERS are invited by the under- signed for 1000 tons (more or less) of B. O. V. and D. O. V. derived from Brimstone or Spent Oxide (of which about 200 tons would be D. O. V.), delivery at the Whitwood Colliery Sidings over 1889. B. O. V. to be 148° to 150° and D. O. V. 168° to 170° Twaddell. The former to be delivered in seller's tank-waggons, and the latter in bottles.

Tenders and samples not later than Tuesday, Dec. 11. Address WHITWOOD CHEMICAL CO., LIMITED., Whitwood Collieries, near NORMANTON.

SURPLUS TAR.

THE Gas Committee of the Corporation of Coventry are prepared to receive TENDERS for the purchase of the SURPLUS TAR produced at their Works, Coventry, for One year from Dec. 31 next. Make, about 1000 tons per annum.

Tenders, stating price per ton delivered into boat, to be addressed to the Manager, and marked "Tender for Tar," not later than Saturday morning, Dec. 15.

The Committee do not bind themselves to accept the highest or any tender.

GEO. WINSTANLEY, Assoc. M. Inst. C.E.
Manager, &c.
Gas-Works, Coventry, Nov. 26, 1888.

SURPLUS TAR.

THE Gas Committee of the Borough of Doncaster invite TENDERS for the SURPLUS TAR produced at their Works in the Holmes, Doncaster, for a period of One, Two, or Three years, to commence Jan. 1, 1889.

The Tar will be delivered into Tank-Barges in the River Don, alongside the Gas-Works, and in no other form.

Tender forms, and any other information, may be obtained on application to Robert Bridge, the Engineer.

Tenders, endorsed on Committee's form, will be received on or before Wednesday, the 12th of December next, by the undersigned.

The Committee do not bind themselves to accept the highest or any tender.

By order,
H. WAINWRIGHT, Chairman.
Gas-Works, Doncaster, Nov. 30, 1888.

BRISTOL UNITED GASLIGHT COMPANY.

AMMONIACAL LIQUOR.

THE Directors of this Company invite TENDERS for the purchase of the AMMONIACAL LIQUOR to be produced at all or either of their three Stations during a period of One, Three, Five, or Seven years, commencing on the 1st day of July, 1889.

The annual quantities and strengths of the Liquor produced at each of the Stations at present are approximately as follows:—

	Gallons.
Canons' Marsh Station, 1,000,000 of 14 ounce Strength.	
Avon Street " 1,300,000 " 15 " "	
Stapleton " 700,000 " 17 " "	

Conditions of Contract, and forms of tender, may be obtained on application to the undersigned, to whom also tenders, sealed, and endorsed "Tender for Ammoniacal Liquor," must be delivered not later than Ten a.m. on Monday, the 28th day of January, 1889.

The Directors do not bind themselves to accept the highest or any tender.

JAS. V. GREEN, Secretary.
Chief Offices: Canons' Marsh,
Bristol, November, 1888.

BRISTOL UNITED GASLIGHT COMPANY.

OXIDE OF IRON.

THE Directors of this Company invite TENDERS for the supply of their requirements of OXIDE OF IRON during the twelve months next ensuing.

Conditions and forms of tender may be obtained on application to the undersigned, to whom also tenders, sealed, and endorsed "Tender for Oxide of Iron," must be delivered not later than Ten a.m. on Monday, the 17th day of December next.

JAS. V. GREEN, Secretary.
Chief Offices: Canons' Marsh,
Bristol, November, 1888.

THE GASLIGHT AND COKE COMPANY.

NOTICE is hereby given, that the TRANSFER BOOKS of this Company, so far as they relate to the DEBENTURE STOCKS and BONDS, will be closed on the Evening of Monday, the 10th of December next, for the Half Year ending the 31st of December, 1888, and that the Interest for that Half Year will be payable on the 1st of January next, to the Proprietors registered as the holders of such Debenture Stocks and Bonds at the time of such closing of the Transfer Books, which will be re-opened for the following Half Year on the Morning of Tuesday, the 11th of December next.

By order,
JOHN ORWELL PHILLIPS,
Secretary and General Manager.
Chief Office: Horseferry Road,
Westminster, S.W., Nov. 10, 1888.

TO ADVERTISERS.

ADVERTISEMENTS for the next number of the JOURNAL must be received by Monday, 12 o'clock noon, to ensure insertion; but as the Advertisement sheet of the JOURNAL is sent to Press the first thing on Monday Morning, Advertisers will please bear in mind that Orders for Alterations in or Stoppages of PERMANENT Advertisements should be received Not Later than Two o'clock on SATURDAYS.

THE JOURNAL OF GAS LIGHTING, WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, DECEMBER 11, 1888.

MR. ALFRED LASS ON GAS COMPANIES' ACCOUNTS.

IN another part of the present issue of the JOURNAL will be found the text of a paper, "On Gas Companies' Accounts," recently read by Mr. Alfred Lass before the Chartered Accountants Students' Society. The author describes his paper as bearing specially upon the reserve, insurance, sinking, and depreciation funds relating to gas undertakings, and on the legislation affecting the same; and it is obviously of advantage to have a record of the views of such an experienced Accountant as Mr. Lass in regard to this class of subjects. Mr. Lass begins by summarizing the history of the introduction of gas lighting and of the early legislation affecting the industry; showing what are the General Acts of Parliament necessary to be studied by those who would understand the conditions under which statutory Gas Companies have to carry on their operations. After this prefatory instruction, the author sets out his subject under eight alphabetically distinguished headings. The bulk of matter is very unequally divided among these classes; for while some headings only require a few paragraphs of explanation, others run into long statements. The history of the form of accounts prescribed by the Act of 1871 is very quickly told; but the discussion of the manner in which Gas Com-

panies may distribute their profits takes Mr. Lass a long way into his paper. His synopsis of the law relating to the payment of dividends and the allocation of gas profits in other ways is very clear and instructive. Upon the question of the right of Gas Companies to establish contingency funds, Mr. Lass is not positive. Such a right may be derived from the Companies Clauses Consolidation Act, 1845; but he says that some authorities hold that this permission is supplanted by the authorization of a reserve fund by the Gas-Works Clauses Act of 1847. The point has never been settled by the Courts; and Mr. Lass admits that Gas Companies have seldom indulged in contingency funds, and to only a small extent. The author goes on to explain the reason for the creation of the optional insurance funds, and also remarks upon the optional and unlimited reserve funds permitted by the latest legislation. He points out a fault in the wording of the model clauses, and declares that the actual state of the law requires amendment to reconcile the general intent of the Act of 1847 with the altered state of things brought about by sliding scale legislation. Mr. Lass discusses the sliding scale, and its actual and prospective effects upon gas consumers and stockholders, and arrives at the prudent reflection that "the auction clauses and sliding scale will not result either in unmixed good or unmixed evil." No man can say anything fairer than this.

After unburdening his mind upon the subject of the sliding scale, Mr. Lass turns his attention to the application of profits of gas making by Local Authorities. He recites the provisions to this effect that are usually found in Special Acts relating to such undertakings—showing that Local Authorities are not bound to keep their accounts in the form prescribed for Gas Companies; that they are authorized to create a sinking fund for the repayment of borrowed moneys; that they may also form limited reserve funds out of profits, and carry any balance of profit to the district or other local fund. Mr. Lass does not mention that this last direction is not usual in the case of Scotch undertakings; nor does he lay quite sufficient stress upon its consequences in the majority of English towns where it is followed. It may be objected that the real object of an accountant's paper should be the facts as they exist, and that comment is not within his province. As he permitted himself to state some of the considerations for and against the sliding scale, however, it would not have been going far out of his way if the author had done the same thing for the similarly "burning question" of municipal gas administration. When he arrives at the division of his paper which deals with repairs, renewals, and depreciation, Mr. Lass pauses, as it were, to draw breath, while directing his readers' attention to the very delicate distinctions and important classifications which come into this branch of the subject. Not Dr. Trench himself could be more solicitous that those whom he addresses should clearly grasp the meanings of the words employed. People in conversation may carelessly transpose the words "repair" and "renew" as though these were synonymous. Not so Mr. Lass; he draws the clear distinction between them, and drives it home. Having duly insisted upon the necessity of clear language, and a just appreciation thereof, Mr. Lass is prepared for grappling with the question of renewals and depreciation, which he does very satisfactorily. He first lays down the data upon which depreciation funds for gas-works may be calculated. Averaging the life of plant, buildings, and apparatus at from 37 to 40 years, he shows that if $1\frac{1}{2}$ per cent. upon the capital cost is taken out of the profits, and allowed to accumulate at compound interest at the rate of 3 per cent. per annum, a fund will be created which will be at all times sufficient for the renewal of the works in perpetuity. After showing, however, that the expense of renewals must come out of revenue, Mr. Lass argues that a special depreciation fund is unnecessary, seeing that the works must be regularly kept up in an efficient condition. He clinches the argument by remarking that the General Acts do not anywhere specially authorize the creation of a depreciation fund, except for works on leasehold lands.

Mr. Lass explains the principle to be followed in allocating the charges for new and enlarged plant as between capital and revenue, and explains the operation of sinking funds for redeeming the cost of works in the hands of Local Authorities. Seeing that he addressed students, it might have been better if Mr. Lass had offered a little more comment upon the difference between the positions of Gas Companies and Municipalities in this regard. All that he says upon this subject is that "the works are, therefore, to be redeemed from debt, as well as repaired and renewed, out of the

"profits derived from the gas consumers." The last section but one of the paper deals with the appointment and position of auditors. Seeing who his audience were, there is much point in Mr. Lass's aspirations after the adoption of the system of official audit "by chartered accountants" for Gas Companies everywhere. It was a sentiment certain to awaken an echo in the breasts of his auditory. In a general way, moreover, the suggestion is not a bad one; but, as the author said, "legislation moves slowly;" and it is to be hoped that the young accountants whom Mr. Lass had in his eye when he spoke will not be compelled to wait for snug auditorial berths until the law is altered in the sense desired. In concluding his paper, the author submits some general reflections upon his subject. He recommends Local Authorities owning gas-works to keep their accounts as strictly as possible in accordance with the form provided by the Act of 1871, and lays stress upon the necessity for solicitude, when making up the accounts of gas undertakings, that charges upon capital and revenue should be fairly apportioned. The ordinary conditions of a trading concern do not apply in such cases; and it is consequently all the more essential that the rights and interests alike of the public and the undertakers should be looked after. Here also Mr. Lass permits himself to make a few remarks upon the vexed question of the subsidizing of district rates out of gas profits; but he is very careful not to offer any opinion regarding the right and wrong of the matter. He points out that the duty of an accountant is clearly to carry out the intentions of the Legislature as expressed in the various Acts of Parliament which he has to consult, without allowing his own prejudices to warp his judgment. This is a piece of counsel that all accountants called in to investigate Gas Companies' accounts in a judicial capacity have not borne in mind. With a final warning respecting the difficulties of the subject of depreciation, the paper concludes. It was rendered more complete by appendices consisting of the forms of accounts scheduled in the Act of 1871, and also an example of the method of analyzing the working results of a Gas Company's operations for a half year. Altogether the paper is a very useful one; and if it does not tell the more experienced of our readers anything new, it contains much useful information to which we direct the attention of some of the perplexed managers and secretaries who are in the habit of writing to us for guidance as to the meaning of some of the references to accounts in the Acts of 1847 and 1871.

THE EMOLUMENTS AND RESPONSIBILITIES OF GAS-WORKS OFFICIALS IN BIRMINGHAM AND ELSEWHERE.

THERE has been a lively discussion by the Birmingham Town Council on the subject of the pay and position of the chief officers of the Corporation Gas Department, arising out of the recent action of the Gas Committee in raising certain salaries without notifying the fact to the Council. It was explained that, in acting as they had done, the Committee had only followed precedent. It appears that when the Corporation acquired the undertakings of the two old Gas Companies, and the water supply, the principle of management adopted by the Gas and Water Committees, and persevered in ever since, was for the Committees to act very much as though they were Boards of Directors. According to this interpretation of their position, the Committees could deal with their officers very much as they thought fit; and so long as the Gas Committee continued to hand over the usual annual subsidy to the Corporation, they did not expect the Council to interfere with their acts of administration in detail. This is a view that appears to have been growing unfashionable in the town; and it has now been finally abandoned, with the consent of both Committees, in favour of the more general course of reporting to the Council proposed increases of salary amounting to £50 or upwards. Following upon the resolution by which this alteration of the principle of administering the Corporation gas and water undertakings was expressed, came a proposal evidently originating in the same circumstances, although more personal in its aim. It was for taking away, as from the end of the year, the advances of salary recently granted by the Gas Committee to Mr. Charles Hunt and Mr. Edwin Smith, the Secretary of the Department. The supporters of this proposal could not argue that the officers in question did not earn their pay; but they objected to the salaries given on the same grounds that are always advanced by orators of the school of that eminent publicist, old Eccles, in "Caste." Happily for the credit of Birmingham, the motion only received five votes against thirty-five. The mover of

the resolution disclaimed any desire to disparage the work of the officers whom he sought to victimize, and referred to the examples of Manchester and Leeds for standards of the pay and position of gas-works officials. This is only what may be expected while these two towns remain quotable for such a purpose. It is necessary, however, that the circumstances both of Manchester and Leeds should be understood. It is true that in both places the Gas Committees are for the present endeavouring to manage their own business "on the cheap;" and a miserable mess they are making of it. The Leeds Corporation are some thousands a year worse off than they were when they had the advantage of Mr. Henry Woodall's advice; and they are able to muddle on as they have done the past few years only because he put them fairly on the road. As for Manchester, we thought everybody knew of the gas supply of this city as a by-word for cost and bad quality, thanks to the wonderful ability of the great unpaid members of the Gas Committee, who have had the works in hand since Mr. West's time. And how was it before him? When Manchester wanted new works, the Corporation Gas Committee went about getting them in the most costly way possible. Having no Engineer in their employ, they invited competitive plans, and engaged Mr. G. Livesey and Mr. William King to select the best for execution. Then they spent vast sums of money in preparing the site for, and building that section of the new station which they least required. What is the recompense received by Mr. Hunt in respect of the new Windsor Street works, in comparison with the money spent for advice alone by the Corporation of Manchester in regard to their Bradford Road works? And which town have the most value for the money? It is such reflections as these that make one disgusted with the narrowness and short-sightedness of some Corporation gas-works administration. Manchester and Leeds, forsooth! If there had not been any proverb declaring the extreme foolishness of the "penny wise," it would have been necessary to make one to fit their case. To return to the case of Birmingham, it may be noticed that, in defending the claims of Mr. Smith to be regarded as something more than an Accountant, Mr. Alderman Pollock described him as General Manager of the gas undertaking. This must surely have been a slip in the warmth of debate, as we are not aware that the Birmingham Gas Department has a General Manager; being managed by a Secretary and two Engineers, who are equally responsible to the Committee.

IMPROVED STREET LIGHTING.

SEVERAL of the London newspapers have been complaining of late of the miserable lighting of the streets of the Metropolis; and the announcement that the Corporation are thinking of dabbling once more in electric lighting only increases the exasperation of the public, who are naturally at a loss to understand why the street lighting authorities do not make better use of the gas they have, instead of waiting for the electricity which is not yet available. This is, in truth, one of the most curious problems of the age in connection with the subject of street lighting. If they put up a good refuge-lamp here and there, the highway authorities think they may leave the rest of their town in semi-darkness. It may be gathered from recent intelligence, however, that here and there local authorities are waking up to a better sense of their responsibilities. Indeed, it would not be too much to say that the reflections which we published a short time since upon the opportunity afforded to murder and outrage by neglect of lighting in the poorer town districts, have also occurred to some of the authorities chargeable with this matter. The Vestry of Newington have ordered all the street lamps in their district to be enlarged to burn 10 cubic feet of gas per hour; and we hear of the doubling of the number of lamps in other parts of the town, besides a general lighting up of dark corners. It is to be hoped that the impulse to this improved public service will not prove transient. The utter wretchedness of much of the usual street lighting is an unfailing topic with the people who seek to supplant gas by electricity; and it is in vain for those who know what gas can do, to speak a word in its favour while the ordinary street lamp remains as an example of how thoroughfares should not be lit. Time was when gas engineers thought that highway authorities had drifted into their common miserly way of using gas by mere force of tradition, and for want of knowledge. Mr. Corbet Woodall, when Engineer of the Phoenix Gas Company, entertained this opinion, and was one of the first to endeavour to break through the force of habit in this matter

by showing how Waterloo Bridge might be lighted by improved gas-lamps. This hopeful view has long been discredited by the general observation that, while a highway authority will cheerfully bear an increased charge for street lighting, provided that the money is to be spent upon inefficient electric lamps, they will not, as a rule, stretch a point to vastly improve the gas lighting which they know they can depend upon. Let us hope that the initiative of the Newington Vestry is the sign of a new departure in this matter.

A PRONOUNCEMENT RESPECTING WATER GAS.

Does anybody know who are the components of the "British Water Gas Syndicate," for whom a Mr. W. L. Wildy, signing himself as engineer, of Leeds, writes in a recent number of *Industries*? If the members of the "Syndicate" are as remarkable in their way as the engineering knowledge exhibited by their representative in his letter, the group must form a curious combination. Our contemporary recently published some remarks, taken from a German source, upon the subject of the dangers of water gas, which Mr. Wildy seems to think reflect upon the projects of his "Syndicate;" and he has accordingly rushed into print in defence. He begins by arguing that it is idle to object to the dangerous character of anything, from football to dynamite, which happens to be cheap and good for some special purpose. The argument is not very strong; because it would be easy to name commodities—such as crude petroleum, and a variety of active poisons—which are not admitted into British trade on account of their dangerous nature, although they might doubtless be useful for some purposes. Mr. Wildy admits that in some communities there is a prejudice, reflected in legislative enactments, against the general distribution of water gas, on account of its containing a high proportion of carbonic oxide; but he triumphantly says that wherever these obstacles existed in the United States they are being swept away, simply because the water gas is cheaper than coal gas, and not only cheaper but better. As to the cheapness, it is of course impossible to lay down any general rule; but Mr. Wildy's peculiar competence to treat of this subject peeps out in his contention that water gas is better than coal gas, because in the first place "its combustion is perfect, under all circumstances, without any smoke." This is, of course, only true of water gas when wholly free from illuminating constituents. Then he says that all the sulphur can be taken out of water gas, which cannot be done for coal gas "without destroying more or less its lighting power." Again, coal gas always flickers and hurts the eyes; while with water gas used to make a light by incandescence, there is no flickering. "Besides, in using water gas there is only half as much heat produced with a similar quantity of light given out, as with common coal gas; and in consequence only half as much carbonic acid introduced into a room." Thus Mr. Wildy thinks that carbonic acid is a direct product of heat. Then for cooking and heating, Mr. Wildy recommends water gas in preference to coal gas, because it does not require any "secondary air." It appears from this strange effusion that Mr. Wildy has attended a few gas engineers' meetings where technical matters have been discussed, and has picked up a smattering acquaintance with such terms as sulphur impurity, carbonic acid, and secondary air, which he uses very much at random. It will tax all his natural and acquired powers to show that, under ordinary English conditions, water gas for illuminating purposes is comparable either in cost or value with common coal gas.

THE HALIFAX GAS-WORKS SCANDAL.—In the House of Commons last Thursday, Mr. Labouchere gave notice that on Monday, he would ask "the President of the Local Government Board whether his attention had been drawn to the *Halifax Times* of the 4th of October, 1888, containing a report of the proceedings of the Halifax Town Council, and to the charges then made in writing against certain gentlemen connected with the Town Council—viz., 'That they had been guilty of fraud and malpractices in connection with the Halifax Gas-Works,' and to the resolution of the Council excluding one of these gentlemen from all Committees of the Council in consequence of such charges; and, whether he will take proceedings to have an official inquiry into the allegations which have been made." Last night, Mr. Ritchie, replying to the question, said that his attention had not been called to the matter. As regards the suggestion that the Local Government Board should make an official inquiry into the allegations, he pointed out that they have no power to inquire into the conduct of members of a town council, or of their officers. Even if there were such powers, he did not think such an inquiry would be expedient. One of the persons implicated was, he remarked, to be tried at the present Leeds Assizes.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 1037.)

THE Stock Exchange markets have generally ruled dull and heavy during the past week. The amount of business done was on a reduced scale, and lack of support caused some departments to give way. But the prime cause of the depression in prices is still to be found in the condition of the Money Market, which has increased rather than abated during the week. If matters do not take a turn the other way, we may see a 6 per cent. rate before Christmas. The Gas Department has formed no exception to the rule of limited business—more especially in the latter portion of the week. The tendency, however, has on the whole been more favourable; and the few variations in price to be noted are, with one exception, in the upward direction. Taking the Metropolitan Companies first: Gaslight "A" has been moderately dealt in, and at remarkably steady figures; the prices never ranging outside 251½-252½. A few transactions have also been marked in the preference stocks, at good average rates. South Metropolitans of all three issues have been fairly active. The "A" shows out strongest, and looks ripe for a little advance. Commercial old, after having been done (on one day only) at more than average figures, made the improvement we referred to last week, by advancing 2. Nothing was done in the new stock. We understand that the tenders invited by the Company for the small balance of 4½ per cent. debenture stock unappropriated were opened on Friday and allotments made. The average price realized was rather in excess of 125 per cent., which must be satisfactory to the Company. Suburban undertakings have not been dealt in; but a quantity of Crystal Palace stock (formerly belonging to Sir Erasmus Wilson) was disposed of at the Mart on Thursday. The prices realized about 206 for the 10 per cent., 146 for the 7 per cent., and 136 for the 6 per cent. preference. Among the foreigners, Continental Union new have made a further rise of ½. [N.B.—In last week's list, the yield upon investment in these shares was, by an obvious error, given as £5 12s. 10d. It should have been £5 17s. 5d.] Other changes are a rise of 1 in Cagliari, and a fall of ½ in Monte Video. Water, though very quiet, has been interesting for the determined advance made by New River. It now looks like resuming the position from which it has been so long displaced. Kent also, which has been very much kept down for some time, jumped up to 280 on Tuesday. West Middlesex and Southwark ordinary, however, are a little easier.

The daily operations were: Fairly good business in Gas on Monday—mostly in Gaslight "A," South Metropolitan "B," and Imperial Continental. Continental Union new rose ½. Water was quiet and unchanged. Gas was rather less active on Tuesday; but prices held firm. Water was brisker, at good figures; but quotations were still left as before. Business in Gas on Wednesday was more limited; but more Companies were dealt in. Cagliari improved 1. Water was quite neglected; and Southwark ordinary dropped 2½. Thursday brought no increase of business in Gas, and prices were only ordinary. Monte Video fell ½. Hardly anything was done in Water; but buyers of Southwark ordinary took another 5 off their price. Gas remained just as quiet on Friday. Commercial old advanced 2, without business done. Water was more active, and for the most part stronger. New River sellers' price rose 6; the debentures changed hands at top price; and Southwark rallied. West Middlesex, however, fell back 1½. On Saturday, Gas offered nothing to remark; being very quiet and unchanged. In Water, Kent rose 3; and Southwark ordinary recovered its loss of Thursday.

ELECTRIC LIGHTING MEMORANDA.

A SENSATIONAL REPORT AND ITS JUSTIFICATION—WINDING UP OF THE PILSEN-JOEL COMPANY—FIRST MEETING OF CROMPTON AND CO., LIMITED—THE FORTUNES OF THE MAXIM-WESTON COMPANY.

It is an old saying that one must leave home to hear news; but it is nevertheless startling to read in the *American Engineer* the announcement that "London is to be lighted by electricity; and it is said the plant will be the largest in the world. The contract has been captured by the Westinghouse people." Although the American printer of this astounding piece of intelligence has omitted to complete the address of the city in question by the customary affix ("Eng."), in order to distinguish it from the other and nearer Londons which local readers are supposed to have in their minds when the word is mentioned, we venture to assume that he means the capital of these islands. This being understood, the real difficulty of the passage stands revealed. Who has determined that London is to be lighted by electricity, and what contract has been captured by the Westinghouse Company? Upon inquiry into this mystery, however, we have discovered more justification for it than appears at a first glance, when it merely looks as though the American reporter had allowed himself to write of London and its lighting arrangements with about as much knowledge as was displayed with regard to other things English by Martin Chuzzlewit's Yankee acquaintances. It appears that the Metropolitan Electric Light Company—the concern mentioned in the parliamentary notices last week as intending to apply for Provisional Orders for the four quarters of London—have given the contract for fitting up their first central station to the Westinghouse Company. We do not know what may be the value of this order; but it seems to have been regarded as of sufficient importance to be telegraphed across to the Westinghouse Company of Pittsburg, and to be by them communicated to the American technical press,

This is the one grain of fact, which, by the application of that "French measurement" of which electricians are so fond, has been expanded into a contract for lighting all London. It is reported that the English electric lighting firms were much chagrined at the Metropolitan Company thus sending abroad their first order; but they have been pacified by the invitation of tenders for the equipment of a second station. By having one station fitted up with American and the other with English plant and machinery, the Metropolitan Company expect to learn which is the better plan by the time they require to extend their resources. Each station is to supply 10,000 incandescent lamps—rather a large order for a Company not yet in possession of statutory powers.

The Pilsen-Joel Company have held their seventh ordinary general meeting, Sir Rawson W. Rawson in the chair. When the Directors last met the proprietors, there was a proposal on for the sale of the business; but a shareholder stigmatized the arrangement as a "job," and moved the Court to prevent it. He succeeded in his immediate endeavours; but the consequence of the action was that the Directors could not carry on the business of the Company, having no money, and no prospect of raising any. At the last meeting, it was therefore a question as to whether any possible means of escape from liquidation could be found. Nothing of the kind presented itself. The shareholders would not find money to throw after their lost capital; and the Directors did not pretend to believe in the possibility of a prosperous future for the Company. There was no quarrelling or recrimination; everybody feeling that the time for that had gone by. When the ship is on the rocks, it is waste of time to blame those who may be suspected of having contributed to the disaster; the best thing is to save what can be taken off the wreck. So the Pilsen-Joel concern is to be voluntarily wound up at last, after a career rather longer than the majority of its contemporaries of the same order.

The same page of the *Electrical Review* which contains the account of the last public meeting of the Pilsen-Joel Company, gives a report of the first general meeting of Crompton and Company, Limited, the formation of which concern we recently noticed. It being only the statutory meeting, there was not much for the Chairman to say; but as it was, he took the opportunity for declaring that the Directors had made themselves fully acquainted with the business, and were satisfied that they had acquired a valuable property. Trade was flourishing, according to this statement, and orders were coming in faster than the Company could execute them. Experience showed that electric lighting could be made to pay; and consequently companies were starting up in all directions to undertake this work. Mr. Crompton would have been happy to have made the acquaintance of the shareholders; but he had gone to Vienna on business connected with his work there for the Imperial Continental Gas Association. All this sounded very well from the chair; but it is not the first time that things have looked rosy at the inaugural meeting of an electrical company. We, of course, place Crompton and Company, Limited, upon a very different footing to that from which the Pilsen-Joel concern has just tumbled; but it is impossible to help thinking they may not always have on their books customers like the Imperial Continental Gas Association, and jobs like the Vienna Opera House lighting.

The Maxim-Weston Company is another of the electrical ventures the proprietors in which must regard their hopeful new rivals with very jaundiced eyes. They held an extraordinary general meeting on the 3rd inst.—one of an already lengthened series—for the purpose of considering a reconstruction scheme. Mr. John Marks presided; and the character of his speeches may be inferred from the fact that a notification has since been published to the effect that proceedings for libel have been taken against him by his notorious predecessor in the chair—Mr. Hugh Watt. The business of the meeting began very quietly. The Chairman explained that, in consequence of the Directors not having been supported in their efforts to raise fresh capital, they had determined upon recommending that the concern should be wound up voluntarily. This recommendation was accepted; but when the names of the proposed liquidators were read out, the liveliness began. The acting Directors were proposed for this employment; but it speedily appeared that information respecting the late Chairman and his doings was urgently required, and this was supplied by the Chairman in speeches of remarkable candour, for which, it appears, he is to be called to account. The net result of the day's proceedings so far as the Company's future is concerned, is that the liquidators are to transfer the business and effects to a new Company with a capital of £75,000 in 3s. shares. It was stated that there would not be any difficulty in floating this new Company, who are to exchange one share, with 2s. credited as paid up, for every share of the old Company. Upon those terms the Maxim-Weston venture is supposed to be able to make a clear start once more. It cannot be denied that they have a good property, as electrical properties go; and, with good luck and good management, they may be able to weather the storm, albeit the outlook is not promising.

The Queen has been pleased to approve of the Borough of Birmingham and the Burgh of Dundee being raised to the rank of Cities.

The Glenboig Union Fire-Clay Company, Limited, of Glasgow, have been awarded three prize medals for goods shown by them at various exhibitions held this year—viz., a silver medal at the Brussels Exhibition; a gold medal at the Barcelona Exhibition; and a first-class medal at the Cardiff Exhibition.

A COMPARISON BETWEEN OIL AND GAS.

THE necessity that exists for a better knowledge as to the capabilities of coal gas amongst consumers of the same, was markedly illustrated by the lecture delivered at Holly Park, by Mr. Defries, an inventor and manufacturer of oil-lamps (see *ante*, p. 991). The best reply that the gas company supplying the district could make to the remarkable line of argument followed by this gentleman in his endeavours, not only to make out the best possible case for his special manufactures, but also the worst for gas, would be to fit up a few dining-rooms and drawing-rooms in the district with gas-burners of the best and most approved modern kind and thus practically illustrate the fact that gas is capable of yielding four or five times the duty that Mr. Defries credits it with. It is only natural that this gentleman should be very strongly prejudiced in favour of oil, and against gas, and of course he is perfectly at liberty to state his opinions; but when he condescends to endeavour to prejudice coal gas by the adoption of a disingenuous and unjust line of argument it is necessary to point out the fallacy of the same. Passing by the popular clap-trap to the effect that gas has got to the top of the tree as an illuminating agent (which is perfectly true, although not in the sense intended by this advocate of oil), has passed the zenith, and is going down hill, we come to the means by which he arrives to his own satisfaction at the conclusion that oil—burnt in a Defries lamp, of course—is only one-fifth the cost of gas. Or in other words, that "when burnt in the best mineral-oil lamp known, and the one in most general use"—i.e., the Defries—it affords a given light at one-fifth the cost of a similar light from gas. The standard of comparison adopted in the lecture is a light of 43 candles for 5 hours, which it is alleged can be obtained by the consumption of one pint of oil. With oil at (say) 8d. per gallon, the cost of this would be 1d., for which a lighting effect of 215 candle-hours is claimed. The subject of gas lighting is approached with great caution, which may be due to ignorance. A Bray's No. 6 fishtail burner is said to generally use 7 or 8 cubic feet per hour, but is taken as using 6 cubic feet, and yielding a light equivalent to 15 candles. Three such burners would be necessary to yield a light of 45 candles. These are alleged to consume in five hours 90 cubic feet of gas, which with gas at 4s. 6d. per 1000 cubic feet would cost 4 $\frac{3}{4}$ d. or say 5d.

We would first point out two or three obvious defects in this argument, all of which tell against gas and in favour of oil. There is nothing estimated for the cost of a wick, or for the extra trouble in cleaning, trimming, replenishing, &c., required with the oil lamp. Then, whereas a duty of 215 candles is required for the oil, 225 candles is the duty obtained from the gas with which it is compared, or an excess of nearly 5 per cent. Then there is another instance of petty inching on, where a cost of 4 $\frac{1}{2}$ d. is said to be practically 5d. These little matters alone, which certainly would not be overlooked by any one desirous of making a fair and just comparison between oil and gas, would reduce the estimated cost to nearer 4d. than 5d.

In the course of a paper read before the Society of Chemical Industry on "The Present Position and Prospects of the Coal Gas Industry," by Mr. Lewis T. Wright, in May last, the following comparison between the cost of oil and gas lighting was given, the standard being 1000 candle hours:—

Best result obtained with mineral oil at	
8d. per gallon after trying various forms	
of lamps	5·63d.
Gas at 2s. 3d. Schulke burner	2·70d.
Wenham burner	3·90d.
Ordinary flat-flame burner	7·70d.

Compared with this standard, Mr. Defries's results work out to—

Mineral oil at 8d.	4·6d.
Gas at 4s. 6d.	23·0d.

The means adopted in order to arrive at this result are patent to everyone. Mr. Defries takes for the basis of the oil calculation, a careful laboratory experiment with his own lamp, which for the present purpose may be accepted as what it is said by its inventor to be, "the best mineral-oil lamp known." But for gas he takes the ordinary burners as used by consumers, which are known to be incapable of developing anything like the best possible lighting effect from the gas. This course is popular with the makers of electric lamps, and enables them to prove (!) to their own satisfaction, that electricity is cheaper than gas, in spite of the known fact that in practice it is found to be equivalent to gas at about 7s. 6d. per 1000 cubic feet. If a fair, honest comparison was desired, both would be put upon the same footing. Either the gas would be burnt in the best-known gas-burner, in which case it would yield some four times the duty credited to it by Mr. Defries; or else ordinary oil lamps that have been some time in common use would be used for the oil. When the Defries lamp, using oil at 8d. per gallon, is compared with the best gas-burners, it will be seen that it is about on a par in regard to cost with ordinary gas at 4s. 6d. per 1000 cubic feet, and this without making any allowance for the extra trouble and attention which it will hardly be disputed is unnecessary in the case of oil. So much for the claims as to the economy of oil. It can be as readily shown that the claim for its superiority are equally as disingenuous, specious, and illusory in their nature.

It was stated that a much steadier light could be obtained from oil than from gas; and the manner in which this point was set forth would lead the listener to believe that owing to some inherent defect, it was impossible to obtain a perfectly steady light by

means of gas. The real facts of the matter are that a flame, whatever its source—whether gas, oil, or candle—will be steady or otherwise according as it is exposed or protected from draughts of air. Expose an oil-flame to the same circumstances as those which obtain in the case of a naked fishtail gas-burner, and it will flicker and smoke to a much greater extent; the oil-flame being much more sensitive to atmospheric influences than the gas. Protect the gas-flame by means of suitable shades, &c., and the light will be perfectly steady. It is almost superfluous to state that if a perfectly steady gas-flame is required, any respectable gas-fitter, who understands his business, would know how to meet the requirement.

The statement that no form of gas-burner has yet been constructed that will perfectly consume all the carbon or sulphur in gas is simply untrue. Can Mr. Defries or anyone else prove the production of unconsumed sulphur from coal gas? This, however, is a matter of no moment, seeing that the quantity of sulphur present is infinitesimal, about one part in 3000, and therefore of no more consequence than the striking of a match tipped with sulphur. As to the escape of unconsumed carbon, this may occur if the flame is left exposed to draught or is otherwise improperly treated. Under proper conditions of use, a gas flame is, if anything, much less likely to give off soot or smoke than an oil-lamp. It is quite true that flowers will not flourish in small rooms where ordinary gas-burners are used; but we have yet to learn that, where modern improved burners are employed, the same effects are noticeable. In any case it is more a question of ventilation, than of the use of gas. Mr. Defries conjures up an appalling vision of a grand sum total of headaches, dyspepsia, and other human miseries, which he hardly asserts are due to the use of coal gas as an illuminant; but on this point, however, proof is wanting. As compared with gas, he claims that oil will not vitiate the air to any appreciable extent; but let us examine the facts. Oil, like gas, consists of carbon and hydrogen; and goes to form water vapour and carbonic acid in the act of combustion. Assuming proper precautions are observed in selecting suitable apparatus, the conversion into these substances will be practically complete. At any rate, we know it is so in the case of coal gas, having seen chimneys of regenerator burners that have been in use for weeks, without the slightest particle of carbon or dust in them. Taking the pint of oil above alluded to, the weight will be about 1½ lbs. Since hydrogen is so light, it only represents a small percentage by weight, and therefore the bulk of this consists of carbon, so it is evident that the pint of oil when burnt will evolve about 3 lbs. or some 25 cubic feet of carbonic acid; whereas 90 cubic feet of gas will weigh something under 3 lbs., of which about three-fourths will consist of carbon, giving a result of rather more than 6 lbs. of carbonic acid. Even with Mr. Defries's excessive estimate, the vitiating effect of coal gas will only be about double that of oil; but if the consumer, desiring to have as pure an atmosphere as possible, elects to take advantage of modern improvements, he can have the same amount of light, as we have seen, with an expenditure of only one-fourth the quantity of gas. By so doing, he reduces to a corresponding extent the vitiating effect on the atmosphere of the room in which the light is used, or to about one-half of that obtaining in the case of oil, thus proving a claim that has repeatedly been advanced on behalf of gas, and never been refuted—viz., that, light for light, gas vitiates the air to a less extent than any other illuminant.

Weight for weight, it is evident that oil will require a smaller quantity of oxygen than gas for complete combustion, because it contains less hydrogen; and that whereas with the oil, carbonic acid is the principal product, there will with gas be also a considerable proportion of water vapour. Approximately it may be said that oil requires twice its weight, and gas three times its weight of oxygen for complete combustion. Oil gives off about three times its weight of carbonic acid, and gas about twice its weight; the remainder of the oxygen coming off as harmless water vapour. This is sufficient to show that any prejudices as to the use of oil allowing a pure atmosphere to obtain, while the use of gas under precisely similar circumstances would render it impure and unwholesome, have no foundation in fact. The public have now used gas for half a century or more, and if the poisonous properties so eloquently dilated upon by Mr. Defries had any real existence, they would long ago have found them out and discarded that means of illumination in consequence. Whether they use gas, oil, or electricity, there is need for improving the ventilation of ordinary domestic apartments; and this is the direction in which to look for improved health, &c., rather than in the substitution of one illuminant for another.

THE THREE-LIFT HOLDER FOR SYDNEY GAS-WORKS.

DESIGNED AND CONSTRUCTED BY MESSRS. C. & W. WALKER,
ENGINEERS, OF LONDON AND DONNINGTON.

DESCRIPTION OF DRAWING No. 2.

This is the general drawing of the guide-framing, giving the position of the joints in the standards, &c. One bay only is shown, as the remaining 21 bays are exactly the same. The pitch of the lattices, and sizes of the iron used, are given throughout; likewise the exact lengths for the diagonal ties, &c.

It will be noticed that the standard tapers from 7 ft. to 2 ft. 6½ in. in the back member; and from 4 ft. 6 in. to 1 ft. 11½ in. in the front. The guide-rail forms part and parcel of the standard; and therefore assists in strengthening the standard. The total height of the standard is 122 ft. 0¼ in. above the base. It is made in five

lengths—the bottom being 22 feet long over all; the top, 24 feet; and the intermediate, 25 feet. These are handy lengths for shipping and for erection. If the holder had been erected in England probably the standard would have been in about 30 feet lengths; and thus reduced the number of joints.

It will be noticed that the same size angle-irons are used for the full height of the standard. This is for convenience. Theoretically they might be reduced somewhat in section as they rise; but it would complicate the work to be done on them. Beyond the taper, the only reduction in weight as the structure rises is in the lattices and tee-iron cross-struts. The former are reduced in three stages, and the latter in two stages; the riveting being the same throughout.

This same drawing No. 2 also shows the detail of the cast-iron base upon which the standard rests. The standard is bolted down firmly to the cast-iron base with twenty 1½-inch bolts passing through the stout wrought-iron plate and angle-irons; so that the casting is made one with the standard. In order to secure a good level bed, the top face of the casting is planed perfectly level; and the whole is then bolted down to the tank pier by the four holding-down bolts previously described. The round holes shown in the base are hand-holes for putting the bolts in by. The base is filled solid with concrete after erection through these holes.

In standards of T-section, it is very common to add a table-plate to the two angle-irons, forming each flange as in sketch "C," instead of two angle-irons only. This is much more costly than the plan adopted, as the table-plates have to be riveted all the way up to the angle-irons, so that there are six lines of rivets extra, extending the whole height of the standard. Again, it makes little recesses for the rain water to settle in at the joints of the lattices (as indicated in sketch "D"), which is objectionable, and

C.

D.

tends to rust away the standard; whereas if only two stout angle-irons are adopted, the way between them is open right through, and no water can lodge. The latter is also easier to paint. Therefore, when the two angle-irons are sufficiently wide for lateral stiffness, it is much better to avoid using table-plates—even leaving economy out of the question. Sometimes the spaces between the angle-irons, &c., are cemented up, to exclude the water.

The objection to tee-iron being used for the flanges is that it lacks lateral stiffness, being narrow on the table. It also puts all the rivets in single shear; thereby weakening the attachment of lattices, &c., and requiring more rivets. More rivets than are necessary for the work are mischievous, as they weaken the structure by cutting away material, beside causing needless expense.

SAFFRON WALDEN CORPORATION WATER-WORKS.—Owing to the hardness (25°) of the water obtained from their works, the Saffron Walden Corporation have decided (under the advice of their Consulting Engineer, Mr. Jabez Church, M. Inst. C.E.) to put up a softening plant, so as to reduce the temporary hardness of the water to 5° or 6°. A Local Government inquiry has already been held; and a loan for this purpose has been granted. The contract for the necessary plant and alteration to the existing works—amounting to £2237—has been let to the National Pure Water Engineering Company, Limited.

CREOSOTING TIMBER.—A zinc creosote process for preserving timber is described in the recently-published volume of "Proceedings of the Institution of Civil Engineers." The experiments from which the data have been obtained are from the observations of Mr. J. P. Caird, an American engineer. After the timber has been prepared in the usual way by steaming and vacuum, dead-oil is run into the cylinder; and so much as may be desired is forced into the wood—half a gallon of oil (or less) to each cubic foot of timber being about the quantity required. The oil is then withdrawn from the cylinder, which is charged with chloride of zinc; and this by pressure is forced into the timber through and beyond the oil. In this way the wood receives the advantage of the dead-oil treatment with the expenditure of one-half, or less, of the usual proportion of oil; and the chloride surrounded by the oil is protected for a lengthened period against moisture. It is stated that this process gives the best result for the money invested.

MODERN DIVINERS EXPOSED.

IN the JOURNAL for Sept. 25, there appeared an article upon the use of the divining rod for finding underground water, in which, after stating some general testimony in support of our proposal to treat the subject in all seriousness, as a matter suited for discussion in a technical publication, we narrated some personal experiences of the manipulation of the rod by Mr. John Stears, of Hull. We then related how, on the occasion of the meeting at Lisburn of the North of Ireland Association of Gas Managers, Mr. Stears astonished the members and their friends by showing, on the indications of a freshly-cut forked hazel twig, which moved in his hands, but apparently without his own volition, the position of the gas and water mains in the high road. Further than this, our testimony did not go. We maintained a particular degree of reserve in commenting upon the exhibition; being careful only to vouch for the actuality of the phenomena brought about through the instrumentality of Mr. Stears, and intimating that further investigation of the mysterious faculty alleged to be possessed by him and by other "diviners" was very desirable. In the same issue of the JOURNAL, and as a footnote to the article referred to, was recorded the contemporary fact of the employment of a diviner named Mullins to discover the best place to sink a well for the supply of the new workhouse at Hastings. Confirmation of Mr. Mullins's indication has not yet come to hand. In the following number of the JOURNAL (Oct. 2), will be found some further communications on the subject; comprising a reprint of a leading article published in the *Morning Post*, and of a batch of correspondence that originally appeared in the columns of the same newspaper. From time to time since then, we have had occasion to mention the subject under various circumstances; for there has seemed to be during the last few months a distinct revival of interest in, and experiments with, the divining-rod, and the matter has been discussed in several prominent newspapers—*Truth* among the number. This recapitulation is necessary to explain the condition of affairs in connection with modern users of the divining-rod up to about a week ago.

One of the correspondents of the *Morning Post* was Mrs. Louise Cotton, a lady who made no secret of her fancy for the so-called "occult" arts of palmistry and astrology, and evidently had a desire to take "rhabdomancy" under her wing. She accordingly issued a public notification of her desire to test the pretensions of such modern diviners as chose to come forward for the purpose; and having secured promises of attendance from four of the class—William Scott Lawrence, described as a stone merchant, living in the neighbourhood of Bristol; John Stears, gas engineer, of Hull; Charles Holt, signalman at Redmile Station (Leicestershire) on the Great Northern Railway; and Alfred Allen, son of a farmer, of Abergele, North Wales—Mrs. Cotton arranged for a demonstration last Saturday week before a small and select body of interested witnesses assembled at the house of Captain Nisbet, "Hollywood," South Kensington. The grounds of Hollywood are admirably suited for the purpose; the garden being about half an acre in extent, and containing somewhere an old well, first dug in 1809, the exact situation of which was only known to Captain Nisbet, who was no believer in the diviners or their art. The programme was that the position of this well should be found, if possible, by the diviners. They one and all accepted the challenge, with the single qualification that, as the rod was supposed to be affected only by running water, they might not be able to hit upon the well itself—the water in which would, of course, be stagnant—but would trace the course of the spring or springs from which the well was fed. This was the order of the day; but what really took place will be found described at length in the report of the representative of *Truth*, which we cannot improve upon, and accordingly reproduce in another column. We endorse from personal observation every line of this statement, which is an unvarnished record of the facts. Not one of the diviners gave the faintest indication of the neighbourhood of the well, although three of them were actually taken over the spot by Captain Nisbet, and all of them passed round about it, in "full cry," many times. They all gave indications of water, after their respective manners, in different parts of the grounds; but they never agreed, except in the vicinity of very obvious hydrants, and from the comments which they offered upon each other's performances, we formed the opinion that they did not put much faith in one another. Mr. Stears found so many indications of water under the grass plots and garden walks, that the ground would have had to be riddled like a rabbit warren to test their truth; but although his twig worked well over a purse, which he said contained a penny and placed on the ground to demonstrate the contrary action of the rod over metal as contrasted with its movement over water, he failed to find a lump of iron purposely trodden into the grass by one of the spectators, although he walked upon it three times. Both Mr. Stears and Mr. Lawrence had indications of water upon revisiting spots which they had previously passed over without any sign; thus leaving it to be inferred that observation of the surroundings may have had something to do with the correction of their earlier divinations. Mr. Stears walked once in silence over the spot between the water-tank and hydrant mentioned in the *Truth* report as the place where Mr. Lawrence became so convulsed; but after seeing Mr. Lawrence perform in this way, Mr. Stears's rod became very sympathetic in the same neighbourhood. The net result of the garden tests, therefore, was disappointment. The diviners declared for the existence of water in many places where Captain Nisbet denied its presence; and they did not discover the well, or even detect the fact that an iron pipe full of water ran straight across the central grass plot, from

one hydrant to another. It was, of course, impossible to say that water did not exist, at any depth, at the spots indicated by the diviners. Indeed, the subsoil of this part of Kensington being gravel, it is more than probable that a well sunk anywhere upon Captain Nisbet's property to the same depth as the actual one—25 feet—would collect water. The diviners did not say anything to this effect, however, nor attempt to explain their failure not only in finding the well, but also in ascertaining the existence of any springs or water courses going to feed it.

When darkness put an end to the experiments in the garden, the company adjourned to the house, where, as the *Truth* reporter tells, Mr. Stears conspicuously broke down over an attempt to find by divination five sovereigns hidden under the cover of a book placed among others on a table. After this incident, Mrs. Cotton read a short paper of a rather rhapsodical cast, in which the genuineness of indications of the rod were taken for granted. Asked afterwards whether she could not have worded her paper differently if she had known that the diviners would fail to satisfy the test conditions accepted by themselves, the lady allowed it to be understood that her faith in the rod was unshaken by the failure of its professors. This was also the state of mind of several of the company, who came with a distinct predisposition in favour of astrology, spiritualism, and similar eccentricities. The matter-of-fact order of spectators, who, like Captain Nisbet himself, began by thinking the whole notion unaccountable and outrageous, but who were yet disposed to give the professors of divination every advantage that they could fairly claim, were left by the experiments with a confirmed belief that the thing is gross humbug. It should be recorded that before the proceedings came to an end on Saturday, a further trial was made of Mr. Stears's powers, with his own consent, the result of which was to still more effectually dispose of his claims in this regard. He stated that he could find any substantial mass of metal; but, remembering his previous failure, he objected to coin. Accordingly a 2 lb. iron weight was procured from Captain Nisbet's kitchen; and when held openly in the hand before Mr. Stears, his rod was strongly affected by it. He expressed himself as being quite satisfied with the object; and all could see that his own powers, whatever they were, had not suffered any deterioration. The weight was then hidden in the drawing-room by one of the company, who also hid 18s. in silver inside a lady's muff lying on an occasional table. Unknown to this gentleman another spectator placed a huge old-fashioned iron doorkey quite openly between the leaves of a book, in such a way that half of its length stuck out. This book and key lay upon a small table standing in a rather dimly lighted part of the room; so that no one would be likely to notice the key unless his attention was directed to it. Mr. Stears then began his search; and although his rod was strongly affected in the neighbourhood of the piano, on account, as he said, of the wires, and also when held over an ottoman obviously provided with metal springs, he failed to detect either the 2 lb. weight, or the heap of silver coin, or the key, although he was repeatedly taken near these objects, and was almost in contact with the last two or three times. This experiment concluded the "business" of the day.

Altogether, we regard last Saturday's doings as extinguishing the reputation of the diviners implicated, and inflicting a deadly blow upon the divining art itself. We do not deny that all the diviners had testimonials from respectable witnesses, who declared that they had succeeded in many instances named; and we do not wish to imply that they are all conscious and deliberate impostors. It is possible for them to believe in themselves to some extent; although, as already remarked, those collected by Mrs. Cotton did not show any great faith in each other. All the same, we hold from Saturday's tests that there is absolutely nothing in the so-called art of divination for water or metals by the rod worthy of the attention of sensible people. One failure in a matter of this kind is more significant than many recorded successes; for one never knows all the circumstances of the successes, nor can discover how far occult art was likely to be aided by more ordinary resources. When the Psychical Society investigated this matter of divination for water, they decided (as recounted by the Honorary Secretary, Mr. Frank Podmore, on Saturday week) that, to be trustworthy, the positive indications of a diviner should be checked by negative indications upon the same authority. For example, it is not sufficient for a diviner to declare that water will be found in a certain spot; he should also be able to indicate a spot where water will not be met with. Otherwise, there is room for the objection that the prediction relating to an underground spring may be mere guesswork, or at best a guess fortified by trained observation and knowledge of the ground. The Committee of the Psychical Society acted upon this principle in their experiment. They employed a diviner, who assured them that water would be found in one part of a certain field, and not in another; but when they had wells sunk in the two places, they found water in both—which, indeed, was to have been expected from geological considerations. The conclusion to be drawn from this experiment of the Psychical Society is precisely the same that follows from Saturday's demonstrations. It will not be shaken even though the Hastings Guardians, who are now sinking for water under the directions of Mullins—a diviner who did not accept Mrs. Louise Cotton's invitation for Saturday—should obtain their desired supply; since in this event there will be nothing to prove the non-existence of water in other parts of the site at their disposal. There exist tens of thousands of people in all grades of the community, however, who cannot or will not weigh evidence

Technical Record.

THE ACCOUNTS OF GAS UNDERTAKINGS.

By ALFRED LASS, F.C.A., Assoc. Inst. C.E.

Last Tuesday evening, Mr. ALFRED LASS, F.C.A., read a paper before the Chartered Accountants' Society in London, taking for his subject "The Accounts of Gas Undertakings, especially in relation to Reserve, Insurance, Sinking, and Depreciation Funds; and the Legislation affecting the same." The paper was as follows:—

The application of coal gas as an illuminant appears to have been discovered in 1792 by William Murdoch, a Scotchman; and the first public display of gas lighting was made in 1802. The first public Company connected with gas lighting was projected in 1807, with the object of obtaining a Royal Charter. The promoter of the Company—F. A. Winsor—desired to raise a capital of one million sterling, and to secure the exclusive privilege of gas lighting in all the British possessions; but being unable to acquire a Charter until an Act of Parliament had been obtained, an application was made in 1809 to incorporate the National Light and Heat Company with a capital of half-a-million sterling, and an exclusive privilege of lighting with gas the whole of London, which application was defeated by Murdoch on the ground of priority in the discovery of the use of gas for lighting purposes. The following year—1810—the Company again applied to Parliament to be incorporated as the London and Westminster Gaslight and Coke Company, with a capital of £200,000, when, after much opposition, they succeeded in obtaining an Act of Incorporation; and two years later—1812—the King granted a Royal Charter, from which period, for nearly 60 years, the Company was called the Chartered Gaslight and Coke Company.

Between 1816 and 1819, applications were made to Parliament by the City of London, the Exeter, Edinburgh, Liverpool, Leeds, Sheffield, and other Gas Companies for statutory powers to supply gas; and from thenceforward to the year 1845 similar applications were almost continuous. During the whole of this period—viz., from 1812 to 1845—all the clauses relating to the authorization of works for making gas and the constitution and management of gas companies were inserted *in extenso* in each Special Act; but in 1845 and 1847 the inconvenience arising from this cumbersome mode of drawing Special Acts was remedied by the passing of the following General Acts, viz.—

"An Act for consolidating in one Act certain provisions usually inserted in Acts with respect to the constitution of companies incorporated for carrying on undertakings of a public nature," commonly called: "The Companies Clauses Consolidation Act, 1845;"

"An Act for consolidating in one Act certain provisions usually inserted in Acts authorizing the taking of lands for undertakings of a public nature," commonly called: "The Lands Clauses Consolidation Act, 1845;"

"An Act for consolidating in one Act certain provisions usually contained in Acts authorizing the making of gas-works for supplying towns with gas," commonly called: "The Gas-Works Clauses Act, 1847;" and

"An Act for consolidating in one Act certain provisions usually contained in Acts for paving, draining, cleansing, lighting, and improving towns," commonly called: "The Towns Improvement Clauses Act, 1847."

These Acts are now incorporated in Special Acts *by reference* only.

General legislation affecting gas supply therefore commenced in 1845 and 1847, since which period the following General Acts, directly or indirectly affecting gas supply, have also been passed, viz.—

Sale of Gas Act	1859
" Amendment Act	1860
Metropolis Gas Act	1860
Lands Clauses Consolidation Acts Amendment Act	1860
Metropolis Gas Amendment Act	1861
Companies Clauses Act	1863
Sale of Gas (Scotland) Act	1864
Companies Clauses Act	1869
Gas and Water Works Facilities Act	1870
Gas-Works Clauses Act	1871
Municipal Corporations (Borough Funds) Act	1872
Gas and Water Works Facilities Act, 1870, Amendment Act	1873
Conspiracy and Protection of Property Act	1875
Public Health Act, 1875 (Gas Supply)	1875
Burghs Gas Supply (Scotland) Act	1876
Lands Clauses (Umpire) Act	1883

The above-mentioned Acts should be carefully read and studied; it being quite impossible within the limits of this paper to set out their effect and scope. Some reference will, however, be made to the Companies Clauses Consolidation Act, 1845, the Gas-Works Clauses Act, 1847, the Metropolis Gas Act, 1860, and the Gas-Works Clauses Act, 1871.

The consideration of the subject of this paper will now be proceeded with in the following order, viz.—

A.—The history of the form of accounts set out in Schedule B to the Gas-Works Clauses Act, 1871; and the application of

in this manner; but if they are so inclined by nature will accept the slenderest bit of positive testimony as outweighing any amount of negative evidence. The divining-rod is only one of the superstitions which are cherished in the present age by people who, though they breathe the atmosphere of our modern civilization, are not of it. Words of comment fail before such a combination of the ancient and modern as a diviner with the rod who is also a signalman of the Great Northern Railway. Moabitish necromancy and the most unromantic of modern callings unite in one person, who, poor man, does not suspect what genealogy belongs to his magician half! Not all the roar and bustle and exactitude of the railway service could prevent the resurrection in Holt's signal-box of the oldest of all known departments of magic. This is a wonderful thing to think of; but it is a line of thought that we cannot enter upon. We have regarded it as a duty to our readers that, having introduced to them the subject of divination in connection with water supply, we should complete the matter by faithfully recounting last Saturday week's experiments.

INSTITUTION OF CIVIL ENGINEERS.—Last Tuesday the ordinary meeting of the Institution was held, under the presidency of Sir George B. Bruce. The first ballot for the session 1888-89 took place, and resulted in the election of 18 members, 87 associate members, and 4 associates. In the first category, we notice the name of Mr. William Davidson, of the Melbourne Water-Works office. Among the associate members elected was Mr. F. S. Cripps, whose articles on "The Guide-Framing of Gasholders" (recently published in the JOURNAL, and now being revised for publication in book form) have been so favourably commented upon at several recent meetings of District Associations of Gas Managers.

THE QUALITY OF THE SOUTH-WEST SUBURBAN WATER COMPANY'S SUPPLY.—Mr. Pickersgill gave notice in the House of Commons, on Thursday last, that on Monday he would ask the President of the Local Government Board, whether complaints had reached him of the bad quality of the water supplied by the South-West Suburban Water Company, who carry on business outside the Metropolis, by virtue of a Private Act of Parliament passed in 1883; and whether there is any power either in the Local Government Board or in any Local Authority to inspect the works of the Company, or in any way to take steps to ensure the purity of the supply, and, if not, whether he will consider the propriety of conferring on extra-metropolitan districts securities similar to those provided for the Metropolis by section 4 of the Metropolis Water Act, 1852, and sections 35 and 36 of the Act of 1871.

LONDON COAL DUES.—In the House of Commons last Tuesday, the President of the Local Government Board was questioned by Mr. Pickersgill as to whether on the expiration of the Metropolitan Coal Dues in July next, there will remain an unappropriated surplus of about £100,000; and, if so, whether the Government will consult the County Council for London before they make any proposals to Parliament as to the disposition of this surplus. Mr. Ritchie, in reply, said he understood that the sum payable in respect of the freeing of the bridges which will fall on the coal and wine dues for the year ending July 5, 1889, was about £350,000. He had no reason to doubt that the coal and wine dues would exceed this sum by £100,000. The Government would be prepared to consider any representations on the subject which might be made to them by the County Council of London.

THE VYRNWY WATER-WORKS.—The impounding of the waters of the artificial Lake Vyrnwy, in Llanwddyn Valley, for the supply of Liverpool, is now in operation. Two of the three valves through the embankment are closed; the remaining valve being open only to the extent of 5 inches for the supply of compensation water along the river bed. Last Tuesday the waters had reached the height of about 30 feet above the bottom of the invert of the discharge tunnels. The effect of this is to cover the village road running from the south-east side of the valley to the north-west side near the old village of Llanwddyn, the houses of which are now nearly all demolished. Some considerable time must, however, elapse before the site of the village is completely submerged by the vast lake, which will eventually be 4 miles in length. Mr. Alderman Bower was able to announce, at the meeting of the Liverpool City Council on Wednesday, that the water was $3\frac{3}{4}$ miles up the lake, which was filling very rapidly.

PRESENTATION TO MR. J. F. BROMLEY.—Last Friday night Mr. J. F. Bromley, the newly appointed Manager of the Batley Corporation Gas-Works, was made the recipient of a valuable marble timepiece and a couple of bronzes to match, from the gas-fitters of the Bolton Corporation, as a mark of their respect and esteem on his leaving Bolton after 30 years' connection with the gas-works—he having began as a fitters' boy, and gradually worked his way up until he held the position of Assistant Manager, as well as Gas Analyst and Superintendent of the Fittings Department. The gathering took place at the Fleece Hotel, Bolton. The company (numbering about 30) that sat down to dinner included Alderman Miles, J.P., the Chairman of the Gas Committee, and who presided at the subsequent proceedings; the vice-chair being occupied by Mr. H. Eccles. In making the presentation on behalf of the men, Alderman Miles referred to the marked ability shown by Mr. Bromley whilst in the service of the Corporation. Mr. Bromley, in acknowledging the gifts, said that whatever he had done under the Corporation, he had always done with the view of studying the interests of those from whom he received his commission, and also of those who were under him.

that Act to those gas companies whose Special Acts incorporate the Gas-Works Clauses Act, 1847.

- B.—The appropriation of the profits of gas undertakings; the formation of the reserve fund; and the powers of gas consumers under the Gas-Works Clauses Act, 1847; the introduction of the auction clauses and sliding scale; the appropriation thereunder of the profits; and the formation of insurance and reserve funds.
- C.—Legislation affecting gas undertakings in the hands of local authorities; the appropriation of the profits; and the formation of sinking and reserve funds.
- D.—Repairs, renewals, and depreciation, showing the principle upon which the calculation for renewals is based.
- E.—Capital and revenue charges; showing the principle to be applied in allocating the same.
- F.—Sinking funds for the redemption of gas-works in the hands of local authorities, or for paying off borrowed capital.
- G.—The appointment and duties of auditors, and the audit of gas accounts by an official auditor, as defined by the Acts of Parliament relating thereto.
- H.—General remarks.
- A.—*The History of the Form of Accounts set out in Schedule B to the Gas-Works Clauses Act, 1871, and the Application of that Act to those Gas Companies whose Special Acts incorporate the Gas-Works Clauses Act, 1847.*

Under the Gas-Works Clauses Act, 1847, each gas company is required to transmit to the Clerk of the Peace yearly an account in abstract of the total receipts and expenditure under the "several distinct heads," with a statement of the balance of such account duly audited and certified; but no form of account is prescribed. It was not until the passing of the Metropolis Gas Act, 1860, that power was given to the Secretary of State to issue a form in which the accounts of the Metropolitan Gas Companies should be kept, and for the year ended Dec. 31, 1862, the accounts of the Metropolitan Gas Companies were presented to both Houses of Parliament in the form prescribed by the Secretary of State, which, in course of time, was enlarged and improved, until shortly before the passing of the Gas-Works Clauses Act, 1871, it became similar to that which is contained in Schedule B to that Act.

By section 35 of the Gas-Works Clauses Act, 1871, the undertakers are to forward to the local authority in each year an annual statement of accounts as near as may be in the form, and containing the particulars specified in Schedule B. The Board of Trade, with the consent of the undertakers, may alter the said forms for the purpose of adapting them to the circumstances of the undertaking, or of better carrying into effect the objects of the section.

Very shortly after the passing of the Gas-Works Clauses Act, 1871, a question arose whether that Act had a retrospective action with regard to those companies whose Special Acts incorporate the Gas-Works Clauses Act, 1847; and in the case of the *Dudley Gas Company v. Warmington*,* the Court decided that the effect of section 3 of the Gas-Works Clauses Act, 1871, together with section 49 of the Gas-Works Clauses Act, 1847, made the provisions of the Gas-Works Clauses Act, 1871, applicable to companies whose Special Acts incorporate the Gas-Works Clauses Act, 1847. Accordingly all gas companies which are subject to the Gas-Works Clauses Act, 1847, are also subject to the Gas-Works Clauses Act, 1871, and are bound (*inter alia*) to keep their accounts in accordance with the form set out in Schedule B to that Act.

- B.—*The Appropriation of the Profits of Gas Undertakings; the Formation of the Reserve Fund and the Powers of Gas Consumers under the Gas-Works Clauses Act, 1847; the Introduction of the Auction Clauses and Sliding Scale; the Appropriation thereunder of the Profits; and the Formation of Insurance and Reserve Funds.*

Companies regulated by the Companies Clauses Consolidation Acts, 1845 and 1863, and the Gas-Works Clauses Act, 1847, are authorized to allot new or additional share capital amongst the shareholders *pro rata* at par, to convert loan capital into share capital, to pay dividends not exceeding the authorized maximum rate, and to appropriate the profits in a certain manner, which appropriation is as follows, viz.:—

- (1) In payment of a dividend at the rate prescribed by the Special Act; and where no rate is so prescribed, 10 per cent.

Note.—Income-tax in addition to the prescribed rate cannot be paid.

- (2) In making up a deficiency in the dividends of any previous year.

Note.—By section 2 of the Metropolis Gas Act, 1860, the payment of back dividends by the Metropolis Gas Companies is limited to six years. Some gas companies have the dividend on portions of their capital limited to the profits of the year. Other gas companies have practically no limitation, and can go back to the date of their Act of Incorporation.

- (3) In the formation of a reserve fund, as follows:—"If the clear profits of the undertaking in any year amount to a larger sum than is sufficient, after making up the deficiency in the dividends of any previous year, to make a dividend at the prescribed rates, the excess beyond the sum necessary for such purpose shall from time to time be invested in Government or other securities; and the dividends and interest arising

from such securities shall also be invested in the same or like securities, in order that the same may accumulate at compound interest until the fund so formed amounts to the prescribed sum; or, if no sum be prescribed, a sum equal to one-tenth of the nominal capital of the undertakers, which sum shall form a reserved fund to answer any deficiency which may at any time happen in the amount of divisible profits, or to meet any extraordinary claim or demand which may at any time arise against the undertakers; and if such fund be at any time reduced, it may thereafter be again restored to the said sum, and so from time to time as often as such reduction shall happen."

- (4) In the reduction of the price of gas.

Gas consumers, therefore, have a direct interest in the proper management and conduct of gas undertakings; and the Legislature has, in section 35 of the Gas-Works Clauses Act, 1847, provided the necessary machinery enabling consumers to apply to the Court of Quarter Sessions for the appointment of an accountant or other proper person to ascertain the actual state and conditions of the concerns of the undertakers, should they consider it necessary so to do. The machinery thus provided has on various occasions been set in motion; but the result has not at all times been satisfactory. One of the most recent cases under this section is that of the *Queen v. The Recorder of Hanley*, relating to the inquiry into the affairs of the British Gaslight Company, which came before the Lord Chief Justice and Justice Denman in the Queen's Bench Division of the High Court of Justice, in July, 1887.* In this case their Lordships found that the Recorder of Hanley had exceeded his jurisdiction in making an order for a reduction in the price of gas, inasmuch as he was obliged to go back over several years to obtain justification for the order. If, said their Lordships, a gas company have not afforded grounds for such an order in the year to which the inquiry is legally directed, the order cannot be made. The inquiry may extend beyond the year, so far as the mere examination of the accounts is concerned; but it is only upon the revenue and position of the company in this particular year that an order can be made.

There is one other point in connection with the appropriation of profits which ought not to be overlooked. Section 122 of the Companies Clauses Consolidation Act, 1845, provides that—"Before apportioning the profits to be divided among the shareholders, the Directors may, if they think fit, set aside thereout such sum as they may think proper to meet contingencies, or for enlarging, repairing, or improving the works connected with the undertaking or any part thereof, and may divide the balance only among the shareholders." It is stated, on good authority, that this clause is inoperative, as the reserve fund of the Gas-Works Clauses Act, 1847, takes the place of the contingency fund of the Act of 1845, and is limited to 10 per cent. on the nominal capital. On the other hand, it is contended that, as the above section has not been repealed by the Gas-Works Clauses Act, 1847, except by implication, it is still operative. If this be so, there is no reason why the profits should not be so reduced by the formation of the contemplated contingent fund as to defeat the object of Parliament, and render it impossible either to create the reserve fund authorized by the Gas-Works Clauses Act, 1847, or to reduce the price of gas. In practice, however, the clause is but seldom acted upon, and then only to a limited extent.

Since 1847, the dividends on new share capital have been limited to $7\frac{1}{2}$ per cent. and 7 per cent.; and in some cases even to a lower rate. Since 1873, the conversion into share capital of borrowed money authorized subsequent to that date has been subjected to a limitation of dividend not exceeding 5 per cent. And since 1877, gas companies have been altogether deprived of the power to allot new share capital amongst the shareholders *pro rata* at par, by the introduction of what are known as the "auction clauses." The Standing Order adopted by both Houses of Parliament in 1877, relating thereto, is as follows, viz.:—"In every Bill by which an existing gas company is authorized to raise additional capital, provision shall be made for the offer of such capital by public auction or tender at the best price which can be obtained, unless the Committee on the Bill shall report that such provisions ought not to be required, with the reasons on which their opinion is founded."

Although shareholders thereupon ceased to have an interest in the issue of additional capital, yet a new and somewhat novel interest was created by the discretionary power given to Committees to insert in all Gas Bills what is known as the "sliding scale," or in the words of the rider attached to the Standing Order—"So to regulate the price of gas to be charged to consumers that any reduction of an authorized standard price shall entitle the company to make a proportionate increase of the authorized dividend, and that any increase above the standard price shall involve a proportionate decrease of the dividend."

The model clauses relating to the sale of shares by auction or tender, the application of the premiums, the sliding scale, the appropriation of the profits and the creation of insurance and reserve funds, can be seen on reference to the Special Gas Acts passed since 1877 authorizing the raising of additional capital, the practical effect of which is as follows:—

- (A) Instead of new capital being allotted to the shareholders *pro rata* at par, it must be sold by auction or tender; and the premiums arising therefrom (after deducting the expenses of, and incident to such issue) are not to be considered as

* See JOURNAL, Vol. XXXV., p. 877; Vol. XXXVII., p. 479.

* See JOURNAL, Vol. L., pp. 82-87.

profit, but are to be expended in extending or improving the works of the company, or in paying off borrowed money, and are not to be considered as capital entitled to dividend.

- (B) Instead of a maximum price, there is a standard price; and instead of the dividends being governed by maximum rates, they are governed by standard rates; the effect of which is that, for every penny of increase or decrease in the standard price, there shall inversely be an increase or decrease of 5s. per cent. in the standard rates.
- (C) Instead of power to create out of the profits of the undertaking a reserve fund equal to one-tenth of the nominal capital of the company to provide for the payment of dividends in case of a deficiency in the amount of the divisible profits, and to meet any extraordinary claim or demand, there is power given to create two funds—viz., an insurance fund and a reserve fund.

The insurance fund (the creation of which is optional) is made up out of the profits of the undertaking in manner directed, and is limited to 1-20th of the paid-up capital of the undertaking, and is to meet any extraordinary claim or demand which may at any time arise from accidents, strikes, or other circumstances, which due care and management could not have prevented; but the reserve fund, instead of being made up out of the profits of the undertaking in the usual way, is made up out of the dividends payable to the shareholders in excess of the standard rates—i.e., assuming the shareholders (in consequence of the price charged for gas being, say, 8d. per 1000 cubic feet below the standard price) to be entitled to an increase of 2 per cent. above the standard rates of dividend, they may, if they think fit, carry to the reserve fund the whole or any portion of such 2 per cent., instead of dividing it amongst themselves. The creation of the reserve fund is therefore also optional, and (in nearly all cases) unlimited; but no reserve fund can be created until after the shareholders have received dividends at the standard rates. Supposing the shareholders, in the exercise of the option thus given, should set apart the whole or some portion of the excess dividends to which they are entitled, then such portion so set aside, together with any reserve or other fund of the company existing at the date of the passing of the company's Special Act, must be invested, and allowed to accumulate at compound interest, forming one fund to be called the reserve fund, which fund is to be applicable to the payment of dividend in any year in which the clear profits of the undertaking shall be insufficient to enable the company in such year to pay dividend at the authorized rates. In some of the Special Acts containing the model clauses, the reserve fund is to provide for any deficiency in the *authorized* rates, and in others to provide for any deficiency in the *standard* rates; but why in some cases it should be called "authorized," and in other cases "standard" does not appear. It should uniformly be either one or the other.

Again, the model clauses are somewhat defective, as they exhaust the whole of the profits of the undertaking without providing for the payment of the excess dividend—as follows:—"If the clear profits of the undertaking of the company in any year amount to a larger sum than is sufficient to pay dividend at the standard rates on the ordinary stock of the company, the excess or such portion of it as is not carried to the insurance fund shall be carried to the credit of the divisible profits of such undertaking for the next following year." This should be amended in the following manner:—"The excess or such portion of it as is not carried to the insurance fund shall, *subject to the payment of the excess dividends if any*, be carried to the credit of the divisible profits of the undertaking for the next following year."

Under section 35 of the Gas-Works Clauses Act, 1847, already referred to, machinery is provided for enabling consumers to apply to a Court of Quarter Sessions for the appointment of an accountant, or other proper person, to ascertain the actual state and conditions of the concerns of the undertakers; and in certain circumstances, a Court of Quarter Sessions has power to order a reduction in the price of gas. But an amended clause, to meet the altered circumstances under the sliding scale appears in a Special Act passed in 1887, a portion of which clause is as follows:—"If it appear to the Court that the profits of the company for the preceding year have exceeded the authorized dividend for that year, having regard to the price charged by the company, and that the whole of the insurance fund has been and then remains invested," the Court "may ascertain and determine to what extent the profits forming such excess would have increased the amount of dividend to the shareholders had the same been divided and paid under the section of this Act, the marginal note of which is 'Dividend dependent upon price charged,' and may make such a reduction in the rate for gas supplied by the company as, in the judgment of the said Court, shall be proper, having regard to the provisions in this Act contained." Having regard to the foregoing observations, it will be seen that some portions of the existing general legislation as well as the model clauses require revising and extending.

The general effect of the auction clauses and sliding scale has perhaps up to the present time been beneficial to both shareholders and consumers. Take, for example, a company which has a standard price of 3s. 6d. per 1000 cubic feet, but is selling gas at 2s. 5d. per 1000 cubic feet; being a reduction in the standard price of 1s. 1d. The selling price of gas being 1s. 1d. per 1000 cubic feet below the standard price entitles the company to pay a dividend at the rate of $3\frac{1}{2}$ per cent. per annum in addition to the standard rate of 10 per cent. or 7 per cent. as the case may be, or at the rate of

5s. per cent. for every penny reduction in price. The consumers, therefore, benefit to the extent of 1s. 1d. per 1000 cubic feet; and the shareholders (if the profits are sufficient) to the extent of $3\frac{1}{2}$ per cent.

Again the auction clauses indirectly benefit both consumers and shareholders, as they are the means of creating as premiums on the sale of shares a considerable capital, which, being non-dividend bearing, reduces the amount to be taken out of the profits to the extent of the dividend thereupon. And although shareholders are not, under the auction clauses, entitled to allotments of shares *pro rata* at par, yet the original holders can to-day obtain in the open market a premium of about £150 for every £100 worth of stock.

Up to the present time the operation of the sliding scale has been on the downward gradient; but supposing it should become necessary for gas companies (in consequence of a continued rise in the coal and labour markets, or a continued fall in the price of residuals) to increase the price of gas so that the sliding scale should move on the upward gradient, it would be interesting to know—(1) what would be the attitude of the gas-consuming public in the face of an increased price of gas? and (2) what would be the attitude of those shareholders who have bought their shares at such a premium as will yield a return of only about 5 per cent., and this return contingent upon the company continuing to sell gas at 2s. 5d. per 1000 cubic feet, and to pay a dividend at the rate of $13\frac{1}{2}$ per cent.?

There are, however, other views of the operation of the sliding scale which must not be lost sight of. It has been said by some authorities that the desire on the part of gas companies to reduce the price of gas and increase the dividends, acts as an incentive to over-economy in the manufacture of gas, especially in that department which relates to the repair and maintenance of works and plant. But probably the operation of the sliding scale has had the effect of stimulating invention and scientific research; and thus of introducing improvements in the methods of distilling coal, and dealing with the products thereof, which have resulted in considerable economy. One thing, however, is certain—that the auction clauses and sliding scale will not result either in *unmixed good* or *unmixed evil*.

C.—*Legislation affecting Gas Undertakings in the Hands of Local Authorities; the appropriation of Profits; and the Formation of Sinking and Reserve Funds.*

Hitherto this paper has dealt exclusively with matters relating to gas companies; but, as local authorities have to some extent acquired the possession of gas undertakings, attention may be profitably directed to the principles which govern such undertakings when in their hands. The power enabling local authorities to construct works and supply gas may be obtained by Provisional Order under the Gas and Water Works Facilities Act, 1870, coupled with section 161 of the Public Health Act, 1875; or those powers may be, and usually are, obtained by Special Act. But such undertakings are not regulated by the Companies Clauses Consolidation Act, 1845, or the Companies Clauses Act, 1863, neither are they subject to all the provisions contained in the Gas-Works Clauses Acts, 1847 and 1871, as will be seen on reference to the following clause, which is usually inserted in such Special Acts—viz., "The provisions of the Gas-Works Clauses Act, 1847 (*except* the provisions with respect to the amount of profit to be received by the undertakers when the gas-works are carried on for their benefit), and of the Gas-Works Clauses Act, 1871, *except* section 35 (accounts, &c.), so far as the same respectively are applicable for the purposes of, and are not varied by, or inconsistent with the Special Act, shall apply to the gas undertaking in the hands of the local authority as if they were authorized by this Act." And, of course, they are not subject to the clauses relating to the sale of shares by auction.

With reference, however, to the accounts of gas undertakings in the hands of local authorities and the appropriation of the profits, the provisions usually inserted in the Special Acts are similar to the following or some of them:—

The local authority shall keep accounts in respect of their gas undertaking separate from all their other accounts, distinguishing therein capital from revenue, and shall apply all money from time to time received by them on account of revenue in manner and in the order following (that is to say):—

(1) In payment of their costs, charges, and expenses of and incidental to the collecting and recovering of gas rents and rates, and of the borrowing of money under this Act.

(2) In payment of the working and establishment expenses and cost of maintenance of their gas undertaking.

(3) In payment of interest on bonds for the time being outstanding.

(4) In payment of the annuities.

(5) In providing the monies required to pay the interest on monies borrowed by them under this Act.

(6) In providing the requisite instalments or sinking fund under this Act; or otherwise making provision for repayment of the monies borrowed under this Act.

(7) In providing a reserve fund, if they think fit, by setting aside such money as they from time to time think fit, and investing the same and the resulting income thereof in securities in which trustees are by law for the time being authorized to invest, and accumulating the same at compound interest, until the fund so formed amounts to (say) £5000, which sum shall be applicable from time to time to answer any deficiency at any time happening to the income of the local authority from their gas undertaking, or to meet any extraordinary claim or demand at any time arising against the local authority in respect of that undertaking, and so that, if that fund is at any time reduced, it may thereafter be again restored to (say) £5000, and so from time to time as often as such reduction happens.

(8) And the local authority shall carry to the district fund any balance remaining in any year, and the annual proceeds of the reserve fund when amounting to (say) £5000.

It will now be seen—

That local authorities possessing gas undertakings are not bound to keep their accounts in the form set out in Schedule B to the Gas-Works Clauses Act, 1871; section 35 of that Act, relating to accounts, &c., being expressly excepted;

That local authorities are authorized to create a sinking fund for repayment of borrowed monies;

That local authorities are authorized to create a reserve fund out of the profits of the undertaking, which is limited, and is applicable to meet any deficiency in the income of the gas undertaking, or any extraordinary claim or demand; and

That local authorities are authorized to carry to the district or other fund any balance of profit.

In some Special Acts relating to gas undertakings in the hands of local authorities, there is provision made for the formation of a depreciation fund at certain fixed rates upon the capital invested.

D.—Repairs, Renewals and Depreciation; showing the Principle upon which the Calculation for Renewals is based.

The subject which is now being approached is an exceedingly important one; and it will be well to understand distinctly the meanings of the words, "repair," "renew," and "depreciate." According to the best authorities they are as follows:—"Repair" means to restore after injury or dilapidation; to amend any injury by an equivalent; to make good for all practical purposes as it was before. "Renew" means to make again absolutely; to restore to the first or original state. We repair that which has been injured we renew that which has become useless or worn out. "Depreciate" means to bring down to a lower price, or to lower the value.

As to Repairs.—Gas-works must at all times be kept in a thorough and efficient state of repair, the cost of which must be charged to the revenue account.

As to Renewals and Depreciation.—The cost of renewals must be charged to the revenue account in one of two ways—viz., Either out of the profits of the year in which the ultimate failure of each portion of the buildings and apparatus occurs, or by setting aside every year out of the profits such a sum as will, if allowed to accumulate at compound interest, provide a fund sufficient to meet renewals as and when they fall due.

Plant and machinery may be repaired; but these repairs will not provide for that imperceptible depreciation or lessening of value which is going on day by day, and which is only made good when the thing depreciated is renewed or restored to its first or original state. Take, for instance, a gasholder. It may be repaired as often as possible, but it cannot be kept in such a state from year to year as, at the expiration of its term of life, to be as good as new. Therefore the gasholder must eventually be renewed by a new one being erected in its place.

In order to show more fully the amount which must be taken out of profits to meet the renewals of buildings, plant, and machinery, let it be assumed that works (exclusive of land), costing £130,000, and capable of producing 200 million cubic feet of gas per annum, are to be of exactly the same size and capacity, and as good in every respect at the end of 100 years as when originally erected, and of equal value. The various portions of the plant, machinery, and apparatus—such as buildings, gasholders, retorts, scrubbers, condensers, mains, &c.—which constitute the works have each a separate length of life; and let it be further assumed that the following table represents the original cost and length of life of each of the respective portions of the plant, together with the cost of renewals during the period of 100 years:—

Portions of Plant, Buildings and Apparatus, Designated by the Letters A to O.	Original Cost.	Life in Years.	Number of Renewals in 100 Years.	Amount of Renewals in 100 Years.
	£			£
A	24,000	100	1	24,000
B	10,000	50	2	20,000
C	8,000	25	4	32,000
D	1,100	3	33½	36,666
E	600	40	2½	1,500
F	3,000	50	2	6,000
G	10,000	40	2½	25,000
H	1,000	25	4	4,000
I	5,000	50	2	10,000
J	800	40	2½	2,000
K	1,500	33½	3	13,500
L	10,000	100	1	10,000
M	10,000	40	2½	25,000
N	2,000	50	2	4,000
O	40,000	40	2½	100,000
	130,000			313,666

Note.—The scrap value, for the purpose of this illustration, has not been taken into consideration.

The renewals in 100 years, therefore, amount to £313,666; or, in other words, the works, which originally cost £130,000, must on an average be renewed 2·41 (or, say, two-and-a-half) times during the period of 100 years. This sum of £313,666 must either be taken out of the profits of the year in which the ultimate failure of each portion of the buildings and apparatus occurs, or it must be provided for by taking out of the profits each year the sum of £1731, or, 1½ per cent. on the sum of £130,000—the original cost of the works—which sum of £1731, if allowed to accumulate at

compound interest at the rate of 3 per cent. per annum, will provide for each renewal during the whole period of 100 years, as and when it falls due.

Thus, whichever mode be adopted, the result will be that the works, which originally cost £130,000, will be, at the end of 100 years, of the same size and capacity, and structurally as good as when first erected, and of equal value. But in large cities and towns where the population is continually increasing, it becomes necessary from time to time, in order to keep pace with the demand for gas, to enlarge the works; and as the works are enlarged, the renewals of the enlarged portions thereof will from time to time have to be provided for. Therefore, if 1½ per cent. upon the total amount expended on the works at the end of each year be yearly taken out of the profits, and allowed to accumulate at compound interest at 3 per cent. per annum, it will at all times (assuming the length of life of each portion of the plant, buildings, and apparatus be taken as above) produce a fund sufficient for the renewal of the works in perpetuity (whatever their size or capacity) once during the average period of life, which for all practical purposes may be taken at from 37 to 40 years.

In all cases where a fund has been allowed to accumulate for the purpose of providing for renewals, that fund, and not the revenue account, must be debited with the cost of such renewals. But as gas companies are not, under the Acts of Parliament regulating their undertakings, authorized to create such a fund (which would certainly have the effect of equalizing the profits), it follows that they must debit the revenue account with the renewals as and when such renewals become necessary. This in some years may have the effect of reducing the profits below the sum required to pay the maximum or standard rate of dividend; and in that case the reserve fund can be resorted to for the purpose of making up the deficiency.

Looking at the many varying and disturbing elements constantly in operation, such as the pulling down of old plant to make room for larger, or the substitution of new scientific appliances in the place of the old, it will be well even for local authorities to debit the revenue account with the renewals as and when such renewals become necessary, rather than create a fund, which, unless worked with the greatest care, must give rise to questions of such a complex nature as will lead to endless confusion and difficulty. In practice, however, renewals are made with some degree of care, foresight, and regularity.

It has now been clearly and conclusively demonstrated that, in providing for renewals out of revenue, a proper provision has been made for depreciation, even for that imperceptible depreciation or lessening in value which is going on day-by-day, and which can only be made good when the thing depreciated is renewed or restored to its first or original state. It therefore follows—whether (a) the works are renewed by charging the revenue with the renewals as and when such renewals become necessary, or (b) by charging the revenue with an annual sum to be set aside and allowed to accumulate at compound interest—that, if the revenue be charged with depreciation in addition to repairs and renewals, such charge for depreciation will not only be wholly unnecessary, but will entail a burden upon gas consumers which ought not to be borne. It may be stated that the General Acts do not anywhere specially authorize the creation of a depreciation fund, except for works on leasehold lands.

E.—Capital and Revenue Charges; showing the Principle to be applied in Allocating the Same.

During the process of continual enlargement (so that works which to-day are capable of producing 100 million cubic feet of gas per year become, in the course of a few years, capable of producing 200 million cubic feet of gas per year), there are introduced many disturbing elements, which render it necessary to properly allocate the expenditure as between capital and revenue.

The following examples will show the principle to be applied:—

(1) Enlargements and extensions. These must be charged to the fixed plant (or capital) account.

(2) Old plant, which originally cost (say) £4000, is pulled down; and the old materials are sold for (say) £200, and enlarged plant is erected at a cost of (say) £10,000.

(a) Debit the sale and credit fixed plant account with the £200.

(b) Debit the revenue account with £3800, the difference between £200 (the value of the old materials) and the original cost of the old plant, and credit fixed plant account therewith.

(c) Debit the fixed plant account with the total cost of the enlarged plant, £10,000.

(3) An old gasholder which originally cost (say) £5000 is pulled down; and the old materials are sold for (say) £250. The tank is converted into a tar-tank at a cost of (say) £200; and a new tank and gasholder are erected at a cost of (say) £20,000.

(a) Debit the sale and credit fixed plant account with the £250.

(b) Debit the revenue account with £4750—the difference between £250 (the value of the old materials) and the original cost of the old gasholder, and credit fixed plant account therewith.

(c) Debit fixed plant account with £200, the cost of converting the old tank into a tar-tank.

(d) Debit the fixed plant account with the total cost of the new tank and gasholder, £20,000; and

Generally adopt the same principle with reference to the mains, services, and meters.

If the above principle be strictly observed, the fixed plant account and the revenue account will each have borne its proper and legitimate burden.

F.—Sinking Funds for the redemption of Gas-Works in the Hands of Local Authorities, or for Paying off Borrowed Capital.

Sinking funds relate only to works and undertakings in the hands of local authorities; and the purposes for which the same are authorized are for paying off moneys borrowed for the erection of such works, or for the purchase of the undertakings, and for extensions and other purposes of the works and undertakings to which capital is applicable.

The clause setting out the mode of repayment in the case of the purchase of a gas undertaking by a local authority is similar to the following—viz., “The local authority shall at the expiration of a period of one year from the transfer, out of the revenue of their gas undertaking, discharge or make provision by means of equal yearly or half-yearly instalments of principal, or of principal and interest, or by means of a sinking fund, or partly in one way and partly in the other, for paying off all moneys borrowed for the purchase of the undertaking, within such period as the local authority may think fit, not exceeding 50 [or 60] years from the transfer; and the local authority shall, at the expiration of one year after the borrowing of any other moneys, in like manner, discharge or make provision for paying off all such other moneys borrowed by the local authority within such period as such local authority may think fit, but not exceeding a period of 50 [or 60] years from the time when such moneys are respectively borrowed.”

The intention of the Legislature is exceedingly clear—viz., that, within a given period, the original purchase-money shall be paid off or provided for by equal annual instalments of principal and interest, or by the creation of a sinking fund out of the profits of the undertaking; thus leaving the works, at the end of the first period of 50 or 60 years (so far as the original purchase-money is concerned), entirely free from debt and unencumbered; and this process must, of course, be repeated with each subsequent loan, so that, at the expiration of the specified period from the date of borrowing, the works may be entirely free therefrom. The works are, therefore, to be redeemed from debt, as well as repaired and renewed, out of the profits derived from the gas consumers.

G.—Appointment and Duties of Auditors and the Audit of Accounts by an Official Auditor, as defined by the Acts of Parliament relating thereto.

Section 101 of the Companies Clauses Consolidation Act, 1845, provides that, except where by the Special Act auditors shall be directed to be appointed otherwise than by the company, the company shall elect the same in like manner as is provided for the election of directors; and section 102 of the same Act states: “Where no other qualification shall be prescribed by the Special Act, every auditor shall have at least one share in the undertaking.” And section 107 states: “That it shall be the duty of such auditors to receive from the directors the half-yearly or other periodical accounts and balance-sheet required to be presented to the shareholders, and to examine the same.” And section 108 empowers the auditors to employ such accountants and other persons as they may think proper, at the expense of the company, and that they may either make a special report on the said accounts or simply confirm the same.

The recognized qualification of auditors under the Companies Clauses Consolidation Act, 1845, is that they must be shareholders, each holding one share at least; and the Legislature has made provision for the possible incapacity of the auditors to perform the duties imposed upon them, by giving them the power to employ accountants to help them in the proper discharge of such duties. This legislation, looking at the importance of the subject, is exceedingly weak and defective; but so far as the Metropolitan Gas Companies are concerned, this was partially remedied during the year 1869, by the introduction of clauses in various Acts relating to the Metropolitan Gas Companies passed in or about that year, authorizing the Board of Trade to appoint an Official Auditor, so that, from the year 1869 to the present time, the accounts of the Metropolitan Gas Companies have, in addition to the audit by the Companies' Auditors, been audited by an Official Auditor appointed by the Board of Trade, in whom are vested the following powers—viz., “The auditor shall during every half year, as and when he thinks fit, inspect the accounts of the company, and audit the same; and if he find the same correct, he shall certify the same, but if he find the accounts incorrect in principle or in detail, he shall require the company to correct the same in such manner as he thinks right, and he may, if he think fit, grant a conditional certificate, so as to authorize the payment of a dividend, subject to correction if need be, and, except in the case of a conditional certificate, a dividend shall not in any case be declared until the accounts are certified by the auditor.” Provision is also made for arbitration should any of the parties interested think themselves aggrieved by any act of the auditor. If the principle of official audit were extended to all gas companies by the appointment of chartered accountants for certain defined districts, it would be a step in the right direction; but legislation moves slowly.

H.—General Remarks.

An attentive and careful study of the form of accounts under the 1871 Act will reveal its simplicity and adaptability. Of course,

certain parts of the form must be somewhat modified to adapt it to the requirements of gas undertakings in the hands of local authorities; but it will be to their advantage to adopt it as far as the same is applicable, as it will enable them (when the necessary calculations are made) to compare the working of their undertakings with the working of other gas undertakings.

Of course when the calculations are made, it requires “technical knowledge” to enable an opinion to be formed as to whether further economies in the manufacture of gas can be effected and in what department, which knowledge must be obtained by experience outside that which ordinary accountancy gives.

In a technical paper such as this, it is unnecessary to enter into the general principles and practice of accountancy. There are both books and papers of great value treating upon these subjects, which are readily accessible; but perhaps it would not be out of place to state that, in making up the accounts of gas undertakings, it should be borne in mind that neither gas companies nor local authorities carrying on gas undertakings are subject to competition or to the ordinary rules of demand and supply, but that within certain defined limits, they have a *quasi* monopoly. In these circumstances, it is very necessary that every allocation as between capital and revenue should be thoughtfully and carefully studied, so as to make such charges only against the capital and revenue accounts as are proper and legitimate, and that the various Acts of Parliament relating to the reserve, insurance, and sinking funds should be carefully read, so as to appropriate the profits in such a manner that the rights and interests of the gas-consuming public are preserved and protected, as well as the rights and interests of the undertakers.

With reference, however, to the clauses in the various Acts of Parliament authorizing local authorities to carry to the district or other fund any balance of profits remaining in any year, opinions may differ as to the expediency or otherwise of taking moneys out of the pockets of gas consumers, and applying them in reduction of those rates which should be borne by the whole of the ratepaying community, consisting of consumers and non-consumers of gas. But the duty of accountants is clear—viz., to carry out as far as possible the intention of the Legislature as expressed in the various Acts of Parliament, and not to allow prejudice to override judgment. The latest legislation bearing upon this point will be found in the Edinburgh and Leith Corporations' Gas Act, passed last session, which provides practically for a supply of gas at such a price as will, after paying the expenses of manufacture, &c., leave as near as may be such a margin of profit only as will provide for the payment of interest on borrowed money and the payment of the sums to be set apart for the reserve and sinking funds; but it must not be forgotten that the “rates” as well as the “undertaking” are pledged as security for the repayment of the purchase-money and other loans which may be raised for the purposes of the undertaking.

[In order to give an idea as to the magnitude of the industry to which the paper referred, some statistics relating to the authorized gas undertakings in the United Kingdom, extracted from the Board of Trade Returns, were supplied.]

In conclusion, looking at the various industries carried on in a country like this—such as gas-works, water-works, railways, tramways, mills, breweries, and factories of all descriptions—and the different processes of manufacture, it is evident that no fixed rate of depreciation can be established for universal application. In these circumstances, accountants must depend upon engineers and others who are technically qualified, for the accuracy of the data upon which the calculations for depreciation are made.

It is important, however, for those who have to deal with the accounts of large manufacturing undertakings, to acquire as much knowledge as to the various rates of depreciation as they possibly can, in order to place themselves in the best possible position to determine (within certain limits) whether or not the capital expended on the buildings, plant, and machinery is fairly represented by the value thereof. There are other things in addition to buildings, plant, and machinery, which are subject to depreciation such as tools, chains, ropes, belting, portable forges, and engines, carts, horses, moulding boxes, patterns, &c., which cannot well be included in an average rate of depreciation, and must therefore be dealt with on a different basis. The whole question relating to depreciation is an exceedingly important one, and demands the closest care and attention.

At the conclusion of the reading of the paper,

Mr. W. EDMONDS, who presided, moved a hearty vote of thanks to Mr. LASS for his kindness in preparing so interesting a paper.

Mr. MURRAY, in seconding the motion, said that from various parts of the paper he gathered that Mr. LASS considered that depreciation was provided for in renewals; but he did not know if he understood rightly. He thought it was generally regarded that repairs and renewals should be charged on revenue. The two charges were somewhat distinct from each other; for in the case of railway and gas companies, there was no need for charges for depreciation, except when the works were built upon leasehold land. With some corporations having gas undertakings under their control, the principle of depreciation was adopted. In certain cases, for instance, a large amount was deducted from the fixed plant account, and charged to revenue year after year; and then additions were made to the fixed plant account for renewals, &c., without any distinction being made between the two. In such an instance, he thought that the mode of keeping the accounts would undoubtedly lead to irregularities, and that the accounts would

not show the exact position of the undertaking as they ought to do. In the case of the Manchester Corporation accounts, which had been kept in this way for the last 30 years, it was contended that the sum which had been deducted from profits—and so taken from the ratepayers—should have been carried over to the city fund; and he thought it was undoubtedly the case that a very large amount had been kept from the ratepayers in this way. In Salford, the adjoining borough, the accounts were also kept in this manner. The revenue account was charged with what was called depreciation; but that depreciation so-called was not written off fixed plant, but carried to the credit of an account against which all renewals were charged in the way suggested by Mr. Lass. So that in this case it was really not proper to call it a depreciation fund. He regarded it as a renewal account, and said that, from the attention he had given to the question, he preferred this mode of dealing with the charge to revenue account by corporations. It equalized profits, as the amount required for renewals, of course, might be much more in one year than in another. He did not like the words "depreciation fund," as he looked upon depreciation as a writing down—a fund to provide for the reduced value of property, and that, therefore, it should be deducted from the property account. In the case of companies, it would be better if the amount of depreciation were carried to the credit of capital account.

The motion having been carried,

Mr. LASS said it had afforded him very great pleasure to prepare the paper; and if those present would read it, they might probably gain a little instruction from it. He concluded by moving a vote of thanks to the Chairman.

SOUTH AFRICAN LIGHTING ASSOCIATION, LIMITED.—The Directors of this Association (whose prospectus appeared in our columns a fortnight ago) met last Friday; and letters of allotment were sent out the following day to applicants for shares.

MR. W. CARR'S TRIAL.—It is not likely that the case of the *Halifax Corporation v. Carr* will come on at the Leeds Assizes before the end of next week. Mr. Tindal Atkinson, Q.C., and Mr. Banks have been retained for the Corporation. Mr. Waddy, Q.C., and Mr. Kershaw will be Counsel for Mr. Carr.

THE USE OF CANDLES IN GAS TESTING.—At last Friday's meeting of the Metropolitan Board of Works, the Clerk reported the receipt of a letter from the South Metropolitan Gas Company, expressing their opinion that the parliamentary standard candle used for testing gas is of a very uncertain and unreliable character, and that it is desirable to obtain parliamentary sanction for the adoption of a new and reliable standard; and asking the Board to receive a deputation from the Company on the subject.

TUSCAN GAS COMPANY.—As will be seen from an advertisement elsewhere to-day, the Directors of the Tuscan Gas Company, Limited, are prepared to receive applications for the balance of £33,000, part of an authorized issue of £60,000 of 5 per cent. debentures of £100 each. The bonds are redeemable, by annual drawings, at £105; a sum being set aside each year to redeem the whole issue within the period of the Company's concessions. The debentures are issued to complete the purchase of the existing gas-works in North Italy, and which are established profitable undertakings. The dividend paid by the Company on its ordinary share capital for the past five years has been $7\frac{1}{2}$ per cent. per annum, free of income-tax; besides providing a redemption fund. The Company already light ten towns in North Italy, all of which are paying and progressive undertakings.

PRESENTATION TO MR. R. H. TOWNSLEY.—The good-feeling existing between Mr. R. H. Townsley, Engineer of the York Street Gas-Works of the Leeds Corporation, and the *employés* was pleasingly manifested, says a correspondent, on the occasion of his marriage with Miss Minnie Newell, of Headingley. As soon as the approaching nuptials "got wind" among the staff, they determined upon giving Mr. Townsley some substantial proof of their esteem; and accordingly the bride and bridegroom were invited to meet the *employés*, on Monday evening of last week, in the reading-room connected with the works, which was prettily decorated with flags, &c. Mr. J. L. Rust, the foreman of the works, presided, and tendered to Mr. Townsley, on behalf of the men, their hearty congratulations; and afterwards presented him with a very handsome marble timepiece, chamber service, and toilet set, together with the following address:—"We the *employés* desire to offer you our most hearty congratulation upon your marriage, and beg your acceptance of the accompanying gift as a token of our respect and good wishes for your own and your bride's future happiness and prosperity. Trusting that you may long be spared to enjoy the esteem of the subscribers," &c. Mr. Townsley said he did not know how to thank his fellow-workmen sufficiently for their handsome present. Intrinsically, it must be of great value; but he did not regard it in that way. He looked at it as showing the goodwill evinced by them towards himself and wife, and so he should ever value it; and no matter how long he lived, he should always look back with pride upon that evening's proceedings. He had only been with them a few months, and that short period greatly enhanced the value of the present, because if he had been with them a long time, they could not have shown their kindness in a more substantial way. The health of Mr. and Mrs. Townsley was then drunk with musical honours; and Mr. Townsley briefly responded. The rest of the evening was happily spent by those present—some of the men adding to the pleasure by songs and recitations.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

GASHOLDER CONSTRUCTION AND THE GUIDE-FRAMING QUESTION.

SIR,—It seems that gasholder construction is about emerging from the reign of the "Golden Rule of Thumb" ("golden" because of its costliness, I suppose). Your Correspondent "Theory and Practice" has put the matter upon a scientific basis in a concise and comprehensive form, and in a manner easily useable, so that in future if we are still to have gasholders with a superabundance of material in them, as is generally the case when working with the "golden rule," let us at least distribute it in something like proportion to what it has to do.

The guide-framing may be said to have shaken off the tyranny of the old rule when it was recognized that it would be better to convert the whole circle of columns into one structure by diagonal bracing, than leave each column to use its own individual strength, aided only by the support of one or two tiers of girders. Now we have got a good scientific guide-framing; and no sooner has this arrived at something like perfection, than it is proposed to do away with it.

The idea of erecting gasholders without guide-framing above the tank is an old favourite of mine; and seven years ago I tried very hard to devise a method for doing it, but did not arrive at anything practical. I have had several attacks of the "fever" since; but with no better results. My efforts ran in the direction of a kind of parallel motion after the style of the old-fashioned parallel ruler; it being clear that if you can keep a gasholder horizontal, the bottom rollers keep it in position, provided the holder be strong enough to retain its proper shape. Although I did not arrive at any practical means of guiding the holder (which I consider Mr. Gadd has done since), I have thought of a way of framing the holder so as to resist distortion; and to lay this before your readers is the object of my letter.

In guiding a holder from the bottom curb, as in Mr. Gadd's invention, we resolve the overturning force of the horizontal wind pressure into a vertical pressure at the windward and leeward side. In an ordinary single lift, with its height (say) a quarter of its diameter, we should be applying the force at the long end of the lever, and thus have only one-quarter the work to do; and this seems the right thing. With inclined guides this vertical force would have to be resolved into one normal to the guide; and this would become greater as the angle with the vertical decreases. It would, in fact, be the vertical force, multiplied by the cosec. of that angle, which at 45° is 1.414, and at $30^\circ = 2$; so that still there is a saving in wear and tear and friction in the rollers. Supposing the holder to be rigid, that part of the wind pressure which tends to slide the holder horizontally from its place is taken by the bottom rollers at right angles or half-way between the windward and leeward tangential rollers. It is, of course, at once clear that, with the inclined guides, one of these rollers will have a tendency to run up the guide and the other to run down; and so we get a new element of distorting stress in the holder, which would now be inclined to tilt sideways in the wind, and indeed will tilt as far as the elasticity of the structure will let it.

The first difficulty in dealing with a holder—speaking only of single and inner lifts now—is the want of rigidity in the whole structure. The top curb may be considered rigid; but the bottom curb is anything but that, and the vertical posts are of very little use except to carry the top when the holder is down, unless they are strongly gusseted to the curbs. Even then their lateral or bending strength alone is available to resist distortion; for, as your correspondent has said, the sheeting cannot be taken into consideration to any great extent, as acting as diagonal ties, on account of its curved form. Two things have to be done in order to make a holder keep its shape—(1) The bottom curb must be kept a true circle; and (2) it must be kept in its true position vertically under the top curb. My first idea, therefore, was to make the bottom curb into a tension-wheel by fixing light rods to it, which are brought to a ring in the centre and tightened up. This would keep the curb a true circle; and its position under the top curb might be maintained by means of diagonal ties between the vertical posts. But the same result will be obtained by taking the rods upwards, and fixing the ring in the centre to the main strut or king-post that supports the crown. In fact, starting *de novo* with the trussing of a holder, supposing it to be devoid of framing, except curbs and vertical posts, make both curbs into tension-wheels and bring the "spokes" to one ring in the centre; making the ring wide enough to allow the centre lines of the "spokes" (top and bottom) all to converge at one point in the centre of the holder at a height exactly midway between top and bottom curb. We thus have a complete diagonally braced rectangle for the section of our holder. The top and bottom curbs, being constrained to keep their circle, act as the horizontal members; the vertical posts are the vertical members; and the two opposite top and bottom "spokes" are diagonal braces. The vertical posts, which would have no "racking" strain, could be light ones, and held from bending sideways under the thrust, by light, straight rods running horizontally from one to the other all round at one or more points of their height, and here and there a little diagonal bracing. In this way a very light and practically rigid holder will be secured; and rigidity is, to my mind, a *sine qua non*, if holders are to be guided from the bottom curb only as in Mr. Gadd's plan. Distortion would be fatal, as it would inevitably lead to jamming, as Mr. H. E. Jones pointed out in last week's JOURNAL. The zigzag guide, I fear, has an extra source of danger, as, at the point of change, opposite rollers might be inclined to take the wrong path.

That the above plan of trussing is feasible is easily seen every day in the bicycles and tricycles on our roads; and without theorizing at all, we may draw an inference from the fact that racing bicycles are made with (say) a 4 ft. 6 in. wheel, the spokes of which do not weigh 1 lb.; and they have to stand not only the weight of the rider, but the enormously greater stress put upon them in propelling the machine.

If it is desired to truss the roof of the holder, the king-post can be brought down to the centre-ring—the top spokes being made stronger to take the extra load; and, if desired, the ring can be placed higher up, which would slightly modify the strength of the rods or "spokes."

The rest of the trussing can be put as usual. On the Continent, they are very fond of constructing the roofs of holders, as well as those of the houses in which holders are usually placed, out of Γ iron only, like an ordinary dome, without any posts or ties; the rafters being in compression, and the purlins and curb in tension.

There is a drawback in my proposed arrangement of spokes—viz., it cannot be used in annular tanks; and if used with a revolving holder, such as Mr. Gadd's, the inlet and outlet pipes would have to be carried to the centre of the holder and inside the ring, which would have to be made large enough to take them in. But in telescopic holders, with the guide-framing carried up only part of the way, it is easily applicable. It also allows a fair amount of "dumping" in the tank; for, as before stated, the ring need not be absolutely in the middle of the height—it may be higher. In tanks with flat bottoms, the lower curbs of the outer lifts could be kept true circles by the same means, only the spokes would have to be horizontal. But here is a difficulty in keeping the upper and lower curbs (grip and cup) in their true vertical positions. One way of doing it would be by using very wide \sqsubset irons for vertical posts, well gusseted at top and bottom, as there is no room in small holders to put diagonals all the way from the top of one stay to the bottom of the next, though, in very large holders, where there are comparatively many stays and the arc between them is a correspondingly small portion of the circle, it might be possible to use bracing in this way; and if it is attempted, one or more horizontal (stiff) rings might be arranged, which would serve the double purpose of strengthening the vertical stays sideways (they could then be made lighter), and at the same time keeping the diagonal bracing out of the way of the inner lifts.

By means of making the curbs into tension-wheels, as above described, we should have gasholders framed complete with all the members subjected only to longitudinal stresses, no bending; and the holder would be a structure in which all the stresses could be determined, and it would be independent of the sheeting which would only have to be strong enough to stand the gas pressure and the working up.

Birmingham, Nov. 30, 1888.

HYPOTHENUSE.

CLECKHEATON LOCAL BOARD GAS SUPPLY.—At the meeting of the Cleckheaton Local Board yesterday week, the Clerk submitted an estimate of the cost of the new gasholders required at the works. The main items were: Land, £2499 17s. 6d.; gasholders, &c., £7795 9s.; contingencies, 10 per cent., £775 11s. It was proposed to borrow £12,000 for the works; and after the estimates had been met, there would thus be a balance of £925 2s. 6d. The Clerk, in reply to Mr. Hirst, said that this £12,000 would include everything connected with the erection of the holders. It was then resolved to apply to the Local Government Board for power to borrow the above-named sum. The Clerk next submitted a statement of the gas revenue, which showed that the Board would be able to reduce the price of gas from 3s. to 2s. 8d. per 1000 cubic feet net; and it was thereupon resolved to reduce the price to this figure.

PROPOSED PURCHASE OF THE OTLEY GAS-WORKS BY THE LOCAL BOARD.—At the meeting of the Otley Local Board yesterday week, a recommendation was made by the General Purposes Committee that a letter be forwarded to the Directors of the Gas Company asking if they were willing to sell their works to the Board. The Chairman (Mr. T. A. Duncan), referring to this matter, said it had been suggested to the Board by the statutory notice which had been given of the Company's intention to apply for a Provisional Order in the ensuing session of Parliament. He had not seen the terms of the application; but it was possible that the Company might be applying for powers which might or might not conflict with the powers of the Local Board. This would be most undesirable; and to avoid it, and at the same time in the interest of the town generally, the Board had deemed it expedient to ask the Company if they were willing to sell their undertaking. Upon the answer would depend the future action of the Board—whether they would take steps in regard to the application, or arrange for negotiating a purchase.

THE TESTING OF GAS-METERS IN DUBLIN.—The testing of gas-meters in the houses of consumers in Dublin has just been commenced, under the direction of Mr. T. J. Cotton, the Gas Inspector to the Corporation. This arrangement, which is expected to prove a great convenience to the inhabitants, has (says the *Freeman's Journal*) been chiefly promoted by Alderman Dillon and Mr. Mayne, M.P. The Corporation, under the Sales of Gas Act of 1859, have authority to test gas-meters as well as the quality of the gas supplied to the city. Since that Act was passed, however, the practice has been for the consumer who believes that his meter is inaccurate to send it to the office of the Gas Committee in East Hanover Street to be tested. This involved the trouble and expense of disconnecting the meter from the service-pipe, conveying it to and from Hanover Street, and then replacing it. In 1884 the Board of Trade made an order that standard meters should be provided for the purpose of enabling the testing of meters in the premises of the consumers to take place. But there was considerable delay in the preparation (under the Board) of a model meter, verified copies of which were to be kept by all local authorities under the Act for the purpose of domestic testing. The difficulties, however, have now been overcome; and the Gas Committee have at the Hanover Street office, under the charge of Mr. Cotton, one of these verified standard meters.

RIPON CORPORATION GAS AND WATER SUPPLY.—The monthly meeting of the Ripon City Council was held on Monday last week, when the subject of turning on the new water supply at the gravitation works on Lumley Moor was discussed. Mr. Collinson maintained that this was being done against the wishes of the Engineer; but the Mayor stated that Mr. Carter's desire was to wait until the pure water well was completed, if the Committee had not expressed a wish to have the water turned on. Alderman Hargrave said if they had to wait for the Engineer, it might be a year or two before the water was turned on. The Town Clerk, in answer to Mr. Smith, said there was a balance in hand on the gravitation water-works capital account of £1300; but he did not know how far this sum would cover outstanding accounts. Alderman Baynes (ex-Mayor) intimated that the ex-Mayor had consented to turn on the new water supply; and it was also stated that a silver key was to be presented to her on the occasion. Mr. Collinson subsequently called attention to the price of gas, and said he was prepared to give notice of a motion that the price be reduced to 2s. 6d. per 1000 feet. The Mayor stated that returns were being prepared as to the gas-works expenditure; and when completed, the Gas Committee would consider the matter. Alderman Hargrave stated that great loss occurred through leakage from the gasholder; and the Gas Manager (Mr. F. Shepherd) said that certain parts of the holder were in bad repair.

Legal Intelligence.

HIGH COURT OF JUSTICE—CHANCERY DIVISION.

FRIDAY, DEC. 7.

(Before Mr. Justice North.)

In re THE CAGLIARI GAS AND WATER COMPANY.

This was an application for the removal of the name of Mr. Frederick Wigan, a Director of the Company, from the register of members; or, in other words, for the cancellation of the registration of certain shares which stood in his name.

Mr. COZENS HARDY, Q.C., in applying for the order, said the matter was brought before the Court under rather peculiar circumstances; and the application was not opposed. The Company was in a very flourishing condition. The shares were at a large premium; and the concessions under which they were working in Italy were very valuable. As long ago as 1868, they resolved to set aside £150 a year in respect of their terminable concessions, by way of sinking fund; and they had, by formal resolution, decided upon the investment of that money in the purchase of shares in the Company, and that the dividends payable thereon should be added from time to time to the Company's reserve fund. This course had accordingly been continuously followed; but was now found to be open to various objections. In the first place, it was *ultra vires* for the Company to make investments in the purchase of their own shares. Striking out Mr. Wigan's name as the owner of the shares would have no effect whatever on the Company, except to make the assets so much more than the liabilities; and the Directors were now perfectly prepared to make their investments in authorized securities. In pursuance of the resolutions mentioned, the shares had been allotted, in the first instance, to Mr. Barrow, who had executed a declaration of trust, in Mr. Wigan's name. There were 377 shares now registered.

His LORDSHIP asked what evidence was adduced of the solvency of the Company.

Mr. HARDY said evidence of the fact was afforded by the high premium of the shares in the market, and that the Company had paid continuous dividends of 7 per cent. The debts due by the Company only amounted to £772.

His LORDSHIP remarked that a further affidavit must be produced, showing the position of the Company with regard to debts and liabilities.

Mr. HARDY suggested that it would not be necessary for more to be shown than that the Company's debts did not exceed the amount which would now be dealt with.

His LORDSHIP said he would be satisfied with that. If the state of matters exhibited by the last balance-sheet were existing at the present time, it would not be necessary to require consent on the part of the creditors to the amount of £772.

Mr. HARDY said he supposed the Court only desired to be assured that the debts were substantially covered.

His LORDSHIP replied that that must be done before he could release from liability a person who was admittedly holder of a considerable number of shares on which, though credited as fully paid up, nothing had been paid, and which were not shown by evidence to be held in pursuance of any contract.

Mr. HARDY said the Secretary of the Company would make an affidavit that the debts due by them did not exceed the £772 of ordinary current debts.

His LORDSHIP observed that he could not point out how the affidavit should be framed. He only wanted to be assured that he would not be prejudicing anybody by releasing a person who at present was under liability in respect of the shares. The matter might be mentioned again to the Court at any time.

HIGH COURT OF JUSTICE—QUEEN'S BENCH DIVISION.

MONDAY, DEC. 3.

(Before Mr. Justice Hawkins and a Common Jury.)

STRUBE v. SOUTHWARK AND VAUXHALL WATER-WORKS COMPANY.

This was an action to recover damages in respect of personal injuries sustained by the plaintiff on May 10, 1886, through the alleged negligence of the defendants' workmen in leaving an open space in the public highway in Edward Street, Penton Place, Kennington Park Road.

Mr. COCK, Q.C., and Mr. FILLAN appeared for the plaintiff; Mr. M'CALL and Mr. GRIFFITHS for the defendants.

Mr. COCK, in opening the case, said the only question for the jury was whether or not the defendants were responsible for the injuries which the plaintiff had sustained, as, in the event of their so holding, the amount of damages had been agreed upon. The plaintiff, who was a master tailor, suffered from sciatica; and, consequently, had to use a stick when walking. On the night in question, his stick caught in a guard-box, which was not provided with a cover, with the result that the plaintiff fell down and fractured his shoulder. One question for consideration was whether the Company did in fact put the guard-box over the supply-pipe; and if so, whether it was a proper and suitable box. Secondly, whether the defendants were responsible. He submitted that, as they were entitled to put the box down, they were responsible. After referring to the various sections of the Water-Works Clauses Acts bearing on the point, the learned Counsel said it was plain that the only duty of the owner of premises was to put in the communication-pipe. In the present case, the Company stated that they did not in fact put in the box. However, whether they did or not, it was clear they provided it; and it was their property according to the decision of the Court in the case of the *East London Water-Works v. Vestry of St. Matthew's, Bethnal Green*.* In that case the Vestry thought the guard-boxes were dangerous, and removed them from the pavement; but the Court held that, as the Water Company had a right to put them down, the Local Authority had no power to interfere with them.

Mr. Strube, the plaintiff, gave evidence supporting the statement of Counsel as to the cause of the accident.

Mr. S. M'Murdie, architect and surveyor, deposed to the guard-box in question being situated 2 feet from the kerb. The pavement was 6 feet in width. There was no cover to this particular box; but many of the boxes had covers.

Mrs. H. Hodgson stated that between 1877 and 1886 she resided in Edward Street, and remembered the box in question being put down opposite her house. The work was done by the Company's men.

Cross-examined: Her reason for saying that the work was done by the Company was because she saw the Company's Inspector there.

His LORDSHIP asked whether there was any dispute as to who did the work.

Mr. M'CALL said the box was supplied by the defendants; but it was not placed in position by their workmen, nor was it the property of the Company. He submitted there was no case to go to the jury.

His LORDSHIP: Supposing I rule that there is no case to go to the jury,

* See JOURNAL, Vol. XLVI., p. 1071 Vol. XLVIII., p. 243.

are you content (if it should turn out hereafter that there was some evidence) to have judgment entered against you, and to take the consequences?

Mr. McCall: Certainly.

Upon the understanding that, should the Divisional Court hold there was evidence to go to the jury, the verdict was to be entered for the plaintiff for £40, his Lordship directed a nonsuit to be entered; the defendants also consenting to a stay of execution until after the judgment of the Divisional Court. With a view of saving expense, his Lordship further advised the parties to see whether some arrangement could not be come to, by which the case could be taken direct to the Court of Appeal; thus saving the costs of a hearing before the Divisional Court.

MANCHESTER ASSIZES—NISI PRIUS COURT.

TUESDAY, NOV. 27.

(Before Mr. Justice WILLS and a Jury.)

HINDLE, NORTON, AND CO., v. DOUGIL.—A GAS-ENGINE CASE.

The plaintiffs in this case are engine makers, of Oldham; and the action was brought for the recovery of £63 1s. 6d. for goods sold and delivered to the defendant.

Mr. ADDISON, Q.C., M.P., and Mr. EASTWOOD appeared for the plaintiffs; Mr. C. A. RUSSELL for the defendant.

Mr. ADDISON, in opening the case, said the plaintiffs were the owners of the "Dougil" gas-engine. In order to push the sale of it, they appointed the defendant Dougil to be their agent at Leeds. Although the name was the same, he had no connection with the patent; it was merely an accidental similarity. The terms were that he should have 15 per cent. upon the net price of cash transactions. Defendant bought the two engines which were in dispute—one in November, 1887—the price being £45, or reckoning the discount, £38. This was an engine of $\frac{1}{2}$ -horse power. The other engine was one of $\frac{1}{2}$ -man power, which was sent to him in July, 1887. Subsequently, he made complaints as to this engine; but the information of the plaintiffs was that he admitted he had tried to get more work out of it than it was capable of. However, the plaintiffs consented to take it back in April of this year; but defendant did not send it. In June there was some disagreement between the parties, in consequence of which defendant sent the two engines back; but the plaintiffs did not receive them. The price of one was £45, and of the other £12; and plaintiffs said they were entitled to have the full price for them from the defendant. The engines were now lying at a railway station in Oldham, at the defendant's risk. Defendant claimed to return them on the ground that they were not merchantable articles. He further said one was worth £6; and the other £1, and had paid the amount into Court. It was also contended that there was an implied warranty that the engines would be noiseless and steady in working; that they could be worked with uniformity of motion, however intermittent the work was; that they would be fitted with governors to regulate the supply of gas; and that they could be started with exceptional ease, and as soon as any other gas-engine that was in the market. This warranty, defendant said, had not been fulfilled, because the engines were defective—defective in manufacture, and not proportioned to the work they were warranted to do. Plaintiffs, however, never warranted them to do any special work, except by describing them as $\frac{1}{2}$ -horse and $\frac{1}{2}$ -man engines respectively. The engines were tested for a week before being sent out; and they worked satisfactorily. What defendant did with the engines he did not know; but he used them or had them used for a long time, and then sent them back. Plaintiffs had seen them, and said that after being cleaned they would still work well. There could be no doubt but that defendant knew what he was buying; and he did not suggest that there was any special warranty.

Mr. E. Norton, one of the plaintiffs, in examination, averred that both the engines in question fulfilled the conditions of the firm's prospectus; being tested before they were sent out, and found satisfactory. They were noiseless and steady in working, made of the best iron, and of good workmanship. He had seen the engines since they were returned, and found them to be all right, except that they were a little dirty.

WEDNESDAY, NOV. 28.

On the case being resumed this morning,

Mr. Norton was cross-examined by Mr. RUSSELL. He admitted that defendant had told him that if he would make the $\frac{1}{2}$ -man engine work properly, he would keep it. He did not make it work properly. He did not know that the piston jammed after working for an hour or two. Upon this point being further pressed,

His Lordship remarked that it was rather a matter for reasoning than for cross-examination. He explained to the Jury that what Mr. Russell suggested was that the piston got hot by the explosions inside the cylinder; and the piston, being surrounded by the cylinder, would not cool as fast as the cylinder—the result being that the cylinder shrank on the heated piston, and became bound.

Cross-examination continued: Neither of the pistons was fitted with rings; and the lubrication of the piston was by hand. The $\frac{1}{2}$ -horse engine was sent to a Mr. Pedley, who made complaints about it.

Re-examined, witness said that they had no complaints of any engines that were supplied for cash; but they had had three complaints respecting engines which were put out on hire by the defendant. Rings were not required on an engine of so small a power as the $\frac{1}{2}$ -man one.

Mr. J. Dougil, the patentee of the engine, deposed to having tested the engines by a friction brake before they were sent out. They behaved perfectly well. When a Dougil engine was started, there was a small space between the piston and the cylinder; but it was filled up by expansion when the engine had been working five or six minutes. Witness went to Mr. Pedley at Leeds, to whom the $\frac{1}{2}$ -horse engine was sold. He found it fitted up with an unsuitable exhaust-pipe. Pedley complained that he could not get up the pressure; and he found it to be due to the exhaust-pipe, and to the slide rods having been lengthened two turns of the screw. Nothing was said to him on that occasion about the piston. Rings were not put on the pistons of other makes of gas-engines.

Cross-examined: He did not take the piston out several times, nor did he file it.

Re-examined: He found that the piston wanted cleaning. It ought to have been cleaned every week; and this was stated on the instructions sent out with the engine.

Mr. Hindle agreed with the last witness as to the cause of the engine not working properly.

Mr. J. Bickerton said he had examined the $\frac{1}{2}$ -horse power engine, and found it to be of good workmanship. He thought the piston was of proper construction, and that rings could be dispensed with. One of the plaintiffs' $\frac{1}{2}$ -horse engines had worked satisfactorily at his place for about twelve months.

Further evidence of a like nature having been given,

Witnesses for the defence were called.

Mr. A. Dougil, examined by Mr. RUSSELL, stated that the $\frac{1}{2}$ -man engine referred to did not work satisfactorily. Mr. Norton tried to make it work; but it stopped before he got out of the show-room. Plaintiffs offered to

take this engine back; but witness wanted to give them every chance to make it right, as he had gone to some expense in advertising the engines, and wanted to reconp himself. In June, however, he sent it back. He did not see the $\frac{1}{2}$ -horse engine after he had sent it to Mr. Pedley, from whom he received a great many complaints respecting it. He sold six of plaintiffs' engines in Leeds. One of these—a $\frac{1}{2}$ -horse—was fairly satisfactory; and two others had been returned.

Cross-examined: The engines in question were returned after disputes with the plaintiffs.

Mr. Marks, the defendant's foreman, said the engine supplied to Mr. Pedley would not work in consequence of the piston jamming. It had never to do more than $\frac{1}{2}$ -horse power, in fact a 2-man Bisschop engine was now doing the work the $\frac{1}{2}$ -horse Dougil machine should have done. The $\frac{1}{2}$ -man Dougil engine would not work at all.

Cross-examined: Witness had seen a number of different makes of gas-engines, but never one, except the Dougil engine, where the pistons were without rings.

Mr. Pedley, of Leeds, said the $\frac{1}{2}$ -horse engine he obtained from the defendant would not do its work at all. Mr. Dougil, the patentee, visited his place to look at the engine. He took the piston out, and began to file it, because it was too large. The piston did not want cleaning. After Mr. Dougil's visit the engine worked no better than before, and he eventually returned it.

Mr. T. Ashbury, M.Inst. C.E., stated that he saw the two engines in dispute in Oldham the day before. The $\frac{1}{2}$ -man was simply a toy engine. He tried the piston of the $\frac{1}{2}$ -horse engine, and worked it by hand. This indicated that there was great looseness of the piston inside the cylinder. The piston had been filed. It was not fit for a gas-engine, because a gas-engine piston should be as tight or tighter than a steam-engine piston. He did not know of any other gas-engine of the same size which had no adjustment for expansion. It was not a workable engine; and it was not worth more than its scrap value. The scrap value was not more than £6—the amount paid into Court.

Mr. H. Bickerton said he had seen several Dougil engines, and condemned the principle on which they were made. It was a non-compression engine; there were no rings in the piston; and the slightest bit of dirt would stop it. It would not work to its nominal power for any length of time.

His Lordship, in summing up, said the question before the jury was whether the engines were really merchantable and saleable articles. He regretted very much indeed that the case was not left to the decision of one thoroughly competent man; for not only had he and the jury to decide questions to which they were not accustomed, but they derived very little assistance from those who ought to give it them. It was a perfect scandal that in such a matter as this, and upon such a question as to whether the "Bisschop" engine ordinarily had rings on or not they should actually have people contradicting one another.

The jury found for the plaintiffs, and judgment was entered for £54 9s., including the money paid into Court. Costs were also allowed.

His Lordship said he would certify, if necessary, that the case was a proper one to come before him.

WESTMINSTER COUNTY COURT.—TUESDAY, DEC. 4.

(Before Mr. FRANCIS BAYLEY, Judge.)

THE GASLIGHT AND COKE COMPANY v. LEACH.

This case which was adjourned on the 16th ult. for the production of further evidence (*ante*, p. 943) came before His Honour to-day. The facts of the case are briefly as follows:—The defendant Mr. G. E. Leach, was for many years a partner in the firm carrying on business in Charterhouse Square, E.C., under the style of G. E. Leach and Co. It was not disputed that the gas was not consumed; but Mr. Leach denied his liability, on the ground that he was not now a partner, having severed his connection with the firm in 1879. When the dissolution of partnership was effected, he wrote to the Company informing them of the fact, and also told the collector that his relations with the firm had terminated. He then removed to Fenchurch Buildings, where the Company laid on the gas for him, and continued to supply him for several years—not a word being said with reference to any previous account; and it was not until quite recently that the present claim was made.

On behalf the Company, it was stated that a letter had not been received from Mr. Leach; and therefore the Company held him liable. If Mr. Leach could produce any document showing that the Company had released him from the contract, then there would, of course, be an end of the matter.

For the defence, a copy of the *London Gazette* was produced to prove the dissolution of partnership on April 29, 1879, which was some months prior to the time for which the claim was made.

On the Company's books being produced in support of the claim, His Honour said he did not think it necessary to go into the books. His opinion was that, although the defendant had not produced any document from the Company releasing him from the contract, he had proved he was not a partner at the time for which the claim was made. The verdict would therefore be for defendant with costs, as well as the costs of the former hearing.

KEIGHLEY CORPORATION GAS SUPPLY.—At the meeting of the Keighley Town Council last Tuesday, it was resolved to empower the Gas Committee, if they thought desirable, to apply to the Local Government Board for a Provisional Order to amend the Keighley Gas Acts, authorizing the Council to raise floating capital.

DEATH OF MR. T. CRAVEN, OF KEIGHLEY.—The sudden death, last Tuesday morning, of Mr. Tom Craven, of Keighley, removes one who took a prominent part in the fight in Parliament, in 1868, between the Bradford Corporation and the then Keighley Local Board on the question of the water supply of the town. Mr. Craven was at that time Chairman of the Water Committee; and he displayed great earnestness in seeing the Committee's scheme carried to a satisfactory completion. The deceased was in his 52nd year.

A PROPOSAL TO PURCHASE THE ST. ANNE'S GAS-WORKS.—At the last meeting of the St. Anne's Local Board, a motion was brought forward by Mr. W. H. Hargreaves to the effect that the local gas-works should be purchased by the Board. He said that every town ought to control its own gas and water supply; for then great inconveniences were avoided. The speaker referred at length to the advantages that would accrue to the ratepayers if they owned the works. As there was no seconder, Mr. Pye said there was something far more important for the good of St. Anne's than the purchase of the gas-works, and that was a sewage scheme. They would sooner or later have to face this question; and it was one that was most urgently needed. Mr. Porritt inquired if the subject Mr. Pye was discoursing upon was relevant to the subject of the motion, to which the Chairman replied that Mr. Pye was rather out of order, but no doubt was taking time by the forelock. The motion was lost.

Miscellaneous News.

BIRMINGHAM CORPORATION GAS SUPPLY.

THE SALARIES QUESTION.

At the Meeting of the Birmingham Town Council last Tuesday—the Mayor (Alderman Barrow) presiding—the question of increasing the salaries of the Corporation officials by Committees, particularly in relation to the Gas Department, was fully discussed.

The Mayor said he desired to call attention to the following notices of motion which had been given, and to suggest that they should be considered together—the latter as an amendment on the former. The first motion was by Mr. Lowe: "That it be an instruction to all such Committees as have been in the habit of increasing the salaries of officials in their employment without obtaining the sanction of the Council that they shall henceforth report to the Council any proposed increase of salary which shall amount to £50 or upwards; and that any previous resolution of the Council which is inconsistent with this present instruction be, and is hereby, to that extent rescinded." The second was by Alderman Dr. Barratt: "That it be an instruction to the several Committees of the Council to report any application or proposal for the advance of the salaries of any of the officers in their respective departments in all cases where the salary of such officer amounts to the sum of £100 or upwards per annum, anything contained in any previous resolution or authority of the Council to the contrary notwithstanding."

The suggestion was adopted.

Mr. Lowe, in proposing the resolution standing in his name, said that at the previous meeting of the Council the resolution he then moved did not go far enough to meet the exigencies of the case. As an amended resolution was then ruled out of order, the discussion came to a somewhat untimely end, and was unceremoniously dismissed. Although they were not altogether agreed as to the nature of the change which should take place, they were, he thought, unanimously of opinion that some alteration should be made, so that for the future it would be impossible for a Committee to act as the Gas Committee had in raising the salaries of their high officials without first obtaining the consent of the Council. A very strong feeling on this subject existed amongst the electors. During the recent contests, it had been his privilege to attend a good many meetings; and he never knew any item of municipal administration which was more strongly condemned than the recent action of the Gas Committee. With the exception of that body, it had been the almost invariable custom of Committees to report to the Council any proposed advances of salary; and that course was a most desirable and proper one to pursue. With this idea in view, he had made his resolution read "any proposed increase of salary which shall amount to £50 and upwards." He had fixed the sum at £50, because he did not believe in the wisdom of compelling Committees to go to the Council for every paltry increase in weekly wages or small salaries, as that would only impede and hamper the work of Committees. For this very reason he could not agree with the notice of motion given by Dr. Barratt.

Mr. BARCLAY also considered that Dr. Barratt's proposal, if passed, would unnecessarily hamper Committees. It might be said that, under Mr. Lowe's resolution, Committees could give frequent increases below the £50, and so avoid the necessity of appealing to the Council; but for his own part he did not think any Committee would act in such an unfair spirit.

Dr. BARRATT then moved his amendment, which, he remarked, he brought forward partly on the ground just stated by the last speaker. To his mind, it would be wise to go back to the old days, when all increases were brought before the Council; and his amendment would bring that result about so far as salaries over £100 a year were concerned. He objected to the £50 limit, as smaller increases could be more frequently given without any application to the Council.

Alderman BAKER, in seconding the amendment, said the change, if made, ought to be thorough and complete.

Mr. BRINSLEY supported Mr. Lowe's motion, remarking that so long as Committees had officers like Mr. Edwin Smith, the Secretary of the Gas Department, they need have no fear of the Council sanctioning reasonable increases in the salaries of their officials.

Mr. THOMASON said he was anxious to define rather more clearly what was really wanted; and he should, therefore, move, as a further amendment—"That henceforth no Committee shall increase the salary of any official until the proposal has been reported to the Council, and approved of by them."

This amendment was not seconded.

Mr. A. C. OSLER suggested that Alderman Barratt should accept a limit of £200 instead of £100. One of the great difficulties in the way of accepting the resolution was that Committees might be unwilling, in view of it, to get the very best men they could for the management of these large undertakings; and, in his opinion, the very best men were always the cheapest. He thought the community would be quite willing to give adequate salaries if there was not a kind of feeling, certainly very widespread at the present time, that with regard to salaries they were being hoodwinked and kept in the dark. If they took the constituencies into their confidence in the fullest manner, this unhealthy feeling would be removed; and the Council would be able to do ample justice to their servants. He moved as an amendment that the limit be £200 instead of £100. Mr. Lowe's resolution, he thought, would increase the feeling of which he had spoken.

Mr. H. C. FULFORD seconded this amendment. He said all the Committees, except the Gas Committee, the Water Committee, and the School of Art Committee were in the habit of reporting increases to the Council.

Mr. DAVIS: Yes; after they have made them.

Mr. LAWLEY PARKER supported Mr. Lowe's resolution.

Alderman Sir THOMAS MARTINEAU observed that the Water Committee, one of those against which he supposed some resolution of the kind was aimed, most cordially accepted the principle of Mr. Lowe's resolution; and, speaking personally, he would, as Chairman of that Committee, just as soon come before the Council with a recommendation for an advance as with a report of one, and asking for approval. There must be a generous confidence shown in Committees to whom the Council relegated the management of large commercial undertakings if the work was to be properly done; but any substantial increase of salaries should come before the Council.

Mr. MICHAEL DAVIS objected to Mr. Lowe's resolution, because under it any Committee could advance an official's salary by steps of £49 19s., until it came to £2000 a year, without consulting the Council. It might be said that present Committees would do no such thing, but gentlemen might come after them who would not be so tenacious of principle.

Alderman POLLACK, Chairman of the Gas Committee, said that his Committee had discussed the matter, and cordially accepted Mr. Lowe's resolution. The Gas Committee were not to blame for not coming to the Council, because the rule of the Committee had been, since it was started, not to report increases of salaries; and he was surprised that such a great

economist as Mr. Michael Davis should have only just discovered that he objected to their action. To those who thought the Gas Committee had acted extravagantly, he should like to say that for several years previous to last year hardly any salaries in the Gas Department had been increased. During the four years in which he was Chairman of the Committee before he was elected Mayor, the increases of salaries only amounted to £300; and in the two years previous to that term, there were only three increases of salary. The Committee had acted probably with a closer fist than if they had come to the Council, because they felt the responsibility which rested upon them. They had not the slightest objection to report to the Council any proposals for increase of salary; and he thought it much better that they should be reported before being granted than afterwards.

Dr. BARRATT said that he would, with the consent of his seconder, adopt the modification of his amendment proposed by Mr. Osler, that increases should be reported in the cases of all salaries over £200.

Alderman COOK supported the amendment.

Alderman LLOYD also agreed that if they were to do anything effective they must adopt Alderman Barratt's amendment, as cases which would be effected by Mr. Lowe's proposition were of very rare occurrence.

Mr. GRANGER also supported the amendment, which he thought took a medium course, and established a principle for the guidance of all the Committees. It should be remembered that the Council was a representative body, and should furnish the burgesses with full information as to its proceedings. It was far better that important increases of salary should be reported rather than be made known by private rumour. A report by a Committee would enable the burgesses to know the merits of some of the men who received the large salaries; and he thought it would be more agreeable to the latter that the salaries should be dealt with in an open and public manner.

Mr. WALSH, referring to the remark that the resolution moved by Mr. Lowe only pointed to certain Committees, said that, while this was so, it did not exonerate the Committees who had been in the habit of reporting increases of salary from continuing to do so.

Mr. ELI BLOOR remarked that when Committees came up with recommendations for increasing salaries, the increase was frequently supported on the ground of the economical management of the department by the official concerned. He thought that in such cases the report should show wherein the economy consisted, as he had found in some instances, from subsequent inquiry, that the alleged economy had been effected either by discharging a number of men and getting the same work done by the remainder, or by reducing wages, or employing boys to do men's work. He knew two or three departments in which this kind of thing had been or was being done.

Mr. H. J. MANTON said he was at a loss to understand how the Council had so suddenly become filled with an excess of virtue in respect to this question of salaries. He believed that both the Committees against which Mr. Lowe's motion was principally aimed were quite prepared to defend their past action.

Mr. LOWE, in reply, referring to the suggestion of Mr. Osler that the instruction of the Council might be evaded by a Committee giving advances of salary by instalments, or, as Mr. Davis hinted, by voting £49 19s. instead of £50, said he did not believe that any member of the Council, let alone one of its Committees, could for a moment be guilty of such dishonourable and unworthy conduct. It was a most shallow and sophistical argument.

Mr. OSLER asked to be allowed to say that he was far from imputing to any of his colleagues that they would do anything dishonourable.

Mr. DAVIS made a similar disclaimer.

Dr. Barratt's amendment was then put to the vote, and lost by 35 votes against 17, and the original resolution was carried.

Mr. WALTER subsequently moved—"That, in the opinion of this Council, the action of the Gas Committee in raising the salaries of Mr. Edwin Smith, Secretary of the Gas Department, and Mr. Charles Hunt, Engineer of the Windsor Street Gas-Works, £250 per year each, was not only an act of discourtesy to the Council, they not having reported the same, but also unnecessary and uncalled for; and considering that the necessities of life are at least 20 per cent. less than they were five years ago, and competition much keener in all trades, this Council instructs the Gas Committee that such increases of salaries named shall cease on the 31st of December next." He remarked that he felt considerable diffidence in moving such a resolution, because it might seem that he wished to assume a dictatorial spirit towards men who had done splendid work for the town. As to Mr. Edwin Smith's work, he considered it was purely accountant's work (cries of "No"). He was not responsible for making the gas, but merely for the accounts; and he (the speaker) thought his salary ought to be guided by what a fair accountant could get in the town. He had made inquiries and found that £800 a year would pay Mr. Smith well for his services. At Leeds, where the gas was 1s. 10d. per 1000 cubic feet, the salaries paid for such work were £350 to one, and £250 to three other officials respectively. In Manchester, four officials were paid, in the aggregate, £1600; while in Birmingham £1200 was paid to one officer. He believed the Council desired to deal with the ratepayers' money as they would deal with their own; but in this matter they were hovering on the lines of extravagance. He was not so foolish as to expect the resolution to be passed; but as he was on the side of justice and truth, he hoped he would gain some support.

Mr. TOWLER, in seconding the resolution, said he had nothing to say, against the officials personally; but in considering the high salaries of the chief officials, he could not overlook the fact that a large number of men were discharged by the late Gas Committee without any remuneration whatever, and many of them were either in the workhouse or walking about the streets penniless. He could give the names of men who had been 20, 30, and 40 years in the service of the Corporation, some of whom were discharged without compensation or with an allowance which was very small after their 30 or 40 years' "slavery." The impression created among the people was that the high officials were well looked after, and the poor workers neglected. Private employers paid higher wages to bricklayers than were paid by the Corporation. If there was a superabundance of money in the hands of the Gas Committee, why not spend some of it in lighting the courts.

Mr. GRANGER spoke in favour of the resolution. It was urged, he said, that Mr. Hunt had saved a Consulting Engineer's commission in the erection of the new Windsor Street works; but those who knew the district said that this had been the very cause of excessive expenditure. It was also stated that these advances had been promised by Mr. Chamberlain; but he did not believe that he had in any way bound his successors. The fact was that there ought to be one Engineer instead of two; for, while it was urged that the present system kept up a useful rivalry, it was obvious, on the other hand, that the same rivalry made it to the interest of each to conceal the causes of bad gas.

Mr. JARVIS felt that the case was one in which the voice and opinions of the electors ought to be considered. The maximum salary of the Manager should be £1000. He would not suggest a reduction; but a readjustment of the two salaries in question to £1000 and £950.

Mr. LOUGHTON believed Mr. Chamberlain had, in fact, promised the officers of the Gas Department that their position should be as good as that of other officers throughout the country. The statement that Mr. Smith was merely an accountant was incorrect, as every one acquainted with the work of the Gas Committee was aware.

Alderman POLLACK concurred in the concluding statement of the last speaker. One would imagine, he continued, that the sole business of the Gas Committee was to deal with salaries. The duty of the Gas Committee was to do its business successfully and remuneratively, to employ such men as would ably assist them in doing so, and to pay those men such salaries as their responsible duties deserved. Mr. Hunt was engaged some thirteen or fourteen years ago; and surely an advance from £800 to £1200 in that time was not excessively rapid. The fault had been, as it seemed to him, that the Committee had not made it gradually. Contrary to what Mr. Granger had said, the Windsor Street works were effecting great economies. Manifestly the question could not be decided by the opinion of Mr. Granger, especially when the Committee were in possession of many facts and reasons which were not known to that gentleman. Mr. Walter was entirely mistaken as to the nature of Mr. Edwin Smith's duties. They were not exactly those of an accountant. The department had an accountant strictly so called. Mr. Smith was the General Manager of the department; and one of his duties was to detect any shortcomings on the part of the Engineers. Mr. Walter appeared to forget that the Gas Committee transacted an enormous amount of business. Their turnover was nearly £500,000. They had not only to deal with the gas accounts, but with several other important matters. There was, for instance, the question of residuals. Two years ago they had a large stock of coke; and they were advised to reduce the price by 1s. or 1s. 6d. a ton. If they reduced it 1s. per ton, it would have been a reduction in the revenue of £7500; but by the vigorous action of Mr. Bishop, in conjunction with Mr. Edwin Smith, they had now no coke left, and it was probable the sale of the coke this year would very largely increase the revenue. There were also a great number of contracts to deal with. If the contract for tar were not properly watched, there would be a difference of perhaps £2000 to £3000 a year; and every penny a ton in the price of the coal meant £1500 a year to the Committee. It was due to Mr. Smith that they were able to buy their coal so economically. Mr. Edwin Smith gave most invaluable advice in respect to all the matters which came under the control of the Committee, who appreciated the value of his work.

Alderman JOHNSON thought that the resolution if passed would be illegal. He did not know the details of Mr. Smith's engagement; but it was an engagement which could not be terminated at a month's notice. By passing the resolution, they could not cancel his engagement by any such notice as Mr. Walter proposed. Mr. Walter urged in support of his resolution the discourtesy of the Gas Committee in not reporting their advances of salary. The Committee, unfortunately, had departed from the spirit and letter of the resolution that they should always report; but were they going to victimize Mr. Edwin Smith because the Gas Committee did not perform their part of the standing order passed when the Gas Committee was constituted? The Committee were empowered by the Council to make a contract with Mr. Smith; and therefore it would become in every sense the contract of the Council. If they passed the resolution, it would have a serious effect on the permanent staff. It would discourage them in their work, because it would be a proclamation to every member of the permanent staff of the Corporation that his salary was at the mercy of a vote taken at any time in the Council. He asked the Council, therefore, to reject the resolution on the ground that it was most mischievous in its character.

The motion was defeated by 35 votes to 5.

IMPORTANT SALES OF SHARES.

By order of the Royal College of Surgeons, Messrs. Thurgood and Martin sold at the Auction Mart, Tokenhouse Yard, last Thursday, £24,780 of stock and 375 fully-paid £6 7 per cent. shares (all *cum div.*) in the *Crystal Palace District Gas Company*. The well-known prosperous and promising character of this undertaking drew together a good number of purchasers, who evinced much eagerness to become possessed of the various lots as offered. Having dilated on the prudent management and the steady growth of the Company's district, the Auctioneer put up for sale, in lots of £250 and £100, a quantity of 10 per cent. ordinary stock, which sold as follows:—£4750, at £205 per cent.; £800, at £207; and £775, at £207 10s. A large parcel of 7 per cent. stock was next offered (divided into similar lots), of which £250 sold at £148 per cent.; £100, at £147 10s.; £2000, at £147; £4800, at £146 10s.; £6235, at £146; and £200, at £145 10s. The final lots of stock sold consisted of £4870 of 6 per cent. (divided as before); and they were disposed of at the following prices:—£2500, at £137 10s.; £400, at £135 10s.; £1970, at £135. The £6 new ordinary shares (earning dividends at the rate of 7 per cent. per annum) produced—300 shares, £8 17s. 6d. each; and 75 shares, £9.

Messrs. Studdards and Stansfield, of Bradford, sold by auction last Tuesday, a number of miscellaneous shares, in which were included shares in various Gas Companies. Three lots of £100 original 10 per cent. stock in the *Shipley Gas Company* were disposed of at £240 each. Fifteen fully-paid £10 shares in the *Redcar Gas Company* fetched £14 per share. Six £10 fully-paid "A" shares in the *Eccleshill Gas Company* realized £18 10s. Fifteen of the *Drighlington Gas Company's* £10 shares (£8 paid) sold for £8 per share. A lot consisting of £120 "B" stock in the same Company was disposed of at £122 10s.

THE LIGHTING OF LIMEHOUSE.—At the last meeting of the Limehouse District Board of Works, Mr. E. Smith called attention to the lighting of the district. He said the Board were paying more for public lighting than they should; and he hoped the Gas Company would see their way to reduce their charges. With this in view, he moved that the question of lighting the district be referred to the Works Committee. The Clerk stated that the charge for lighting was £39s. per lamp annually, including the painting of the columns, lighting the gas, and repair of broken glass. Mr. Hopson seconded the motion, which was carried.

THE PROPOSED ELECTRIC LIGHTING OF COWPEN.—Last Wednesday an informal meeting of a Committee composed of all the members of the Cowpen Local Board was held to consider the advisability of lighting the town with electricity. The Chairman (Mr. Robinson) said he had called the meeting for the purpose of hearing an explanation from Mr. Nicholson, of Messrs. Jennings and Nicholson, electrical engineers, of London. After the explanation and conference, a memorandum of agreement was drawn up and initialled by the Chairman on behalf of the Board, and Mr. Nicholson on behalf of his firm, for lighting the township by electricity. On Friday, at a special meeting of the Local Board, it was unanimously decided that the tender of Messrs. Jennings and Nicholson, to light Cowpen township with 18 arc lights for £575 per annum, with option to purchase the plant during the five years' term, be accepted. The township has been in darkness since August; so that considerable satisfaction is expressed with the decision of the Board.

THE GAS COAL CONTRACTS OF THE BURY CORPORATION.

On Thursday last, at the Meeting of the Bury Town Council—the Mayor (Mr. Alderman Smethurst) presiding—the Gas Committee presented minutes, from which it appeared that at their meeting tenders for coal were opened and initialled, and ordered to be tabulated and laid before the next meeting; and the Chairman (Mr. Alderman Burrow) read to the Committee some correspondence that had taken place between himself, the Manager, and Mr. Ellis Lever.

Mr. BENTLEY called attention to the minute referring to the correspondence, and moved that it be read. He said he need not remind the Council that the name of Mr. Ellis Lever had been pretty prominent in connection with gas-works and municipal corporations. He did not know what the object referred to was; but he thought it desirable, as long as his name was in the minutes, that the letters should be read.

Alderman BURROW had no objection to this being done, if it was the wish of the Council. He did not think it advisable that all the correspondence, which the members of the Council did not know the tenor of, should be made public; although the Council might have the right to know of it. Mr. Bentley should have given him notice of his motion. But fortunately he had the letters with him; otherwise he would have had to ask the Council to wait whilst he sent for them.

Mr. MOZLEY moved that every member have an opportunity of seeing the correspondence at the gas offices.

Some conversation took place as to whether the Chairman of the Committee should read the correspondence, when

Mr. ALCOCK said it would be simply a waste of time. If any person who had an interest in the question had the liberty of perusing the correspondence, it would meet the case.

The minutes were then confirmed, on the understanding that Mr. Alcock's suggestion should be carried out.

The *Bury Times*, referring to the matter, thinks the Council made a mistake in not having the letters read. "We do not," says the local paper, "suppose that anything like what has occurred at Salford or Halifax is about to be disclosed in connection with Bury. Still, as Mr. Lever is something like a stormy petrel in connection with gas-works, and as Alderman Burrow said he had the letters with him, and had no objection to read them if the Council wished him to do so, it was a pity the Council should not have accepted his offer. Had the letters been read, or even a summary of them given, it might have been the best for all parties. There are people ready enough to think there may be something to conceal. It is clear the letters should not have been named in the minutes—or they should have had their purport disclosed—if only to prevent statements going abroad which may be altogether untrue and unfair."

SALFORD CORPORATION GAS SUPPLY.

THE ALLEGED FRAUDS IN THE GAS DEPARTMENT.

At the Monthly Meeting of the Salford Town Council last Wednesday—the Mayor (Mr. Alderman A. L. Dickens) presiding—the correspondence which had taken place with Mr. Ellis Lever with reference to certain alleged frauds in the Gas Department was submitted.

The Mayor said that some letters had passed between the Council and Mr. Ellis Lever with regard to that gentleman's offer to show the ratepayers how they had been defrauded; and the upshot of it all was that Mr. Lever had declined to accept the terms of the Corporation. The Mayor then read the correspondence. The first letter, dated Nov. 22, was from the Town Clerk to Mr. Lever, and was as follows:—

I beg to forward you copy of resolution passed by my Council yesterday. You must understand that in case your two nominees should not appoint his Worship the Mayor the third gentleman to meet you, the meeting must be held outside the Town Hall; but, of course, in case his Worship is the third member, the meeting may be held here.

The resolution enclosed was in the following words:—

Resolved, that the proposal of Mr. Ellis Lever to nominate two members of the Council, who, being so nominated, shall themselves appoint a third, to whom he will disclose the frauds alleged to be going on in the supply of coal for the Gas Department, be accepted, and that the members so selected shall receive such evidence and report the result to the Council.

To this letter and enclosure, Messrs. Dendy and Paterson, Mr. Lever's Solicitors, on Nov. 28, wrote—

On his return from Wales yesterday, Mr. Lever handed us your letter of the 22nd inst. enclosing a document purporting to be a resolution passed by the Council on the previous day. In the discussion which took place, the Council appeared to ignore the fact that the offer made by our client on the 26th of September had been formally withdrawn by us in his behalf, for the reasons stated in our letter addressed to the Mayor on the 8th inst., which you published. Even if the offer had not been withdrawn, the resolution you send, and the letter accompanying it, contain conditions to which we could not advise our client to assent. When you tell him, although not authorized by the resolution to do so, that, unless the Mayor is the third person nominated, Mr. Lever and his nominees should not be permitted within the Town Hall, the only construction which our client can place upon a deliberate affront of that nature, following the obstacles put in his way on former occasions, is that his presence and assistance are not desired.

Alderman KEEFNEY asked if he might understand that the Committee could have met either in the Gas Offices or anywhere else, at Mr. Lever's request, if he had accepted the proposal.

The Mayor replied in the affirmative.

Mr. RYECROFT observed that having since his election to the Council, taken a somewhat prominent part in the gas affairs of the Corporation, he must express his regret at what appeared to be the utter collapse of the negotiations between Mr. Ellis Lever and the Corporation in reference to the communication of certain information which Mr. Lever publicly announced he was able to furnish. He was afraid the Council was largely to blame for this result. If the Council, as it undoubtedly should have done, had promptly and without reservation accepted Mr. Lever's offer, he would have had no alternative but to carry out the promise he made; but the manner in which the Council, in its unwisdom, approached the matter was not calculated to inspire Mr. Lever with confidence. He trusted, however, that Mr. Lever would not let the public suffer in consequence of the infirmity of those who were sent to safeguard their interests; but that he would reconsider the position, and let the information be available for exposing any past or present malpractices in the Gas Department. That the burgesses of Salford were greatly indebted to Mr. Lever could not be denied; and it did seem strange that he should have been treated with such scant courtesy. He refused altogether to be drawn away by side-issues. The sole questions they, as a Corporation, had to consider were: Had they been defrauded? (and of that there was no manner of doubt), and By whom? To say that A. was no better than B., or, as a prominent statesman put it, "You're another," did not, in his opinion, advance the matter at all.

The Mayor said Mr. Lever would probably have plenty to do for some little time to answer the letter which had been published in the *City News*. If that letter was answered satisfactorily, it would answer the purposes of the Council.

* This is the letter which appeared in the JOURNAL for the 27th ult. (p. 941).

Mr. B. ROBINSON thought the matter ought not to be allowed to rest where it was; because a serious imputation had been cast upon the Council as well as upon the Gas Committee.

The Mayor: You can put it on the *agenda* paper for the next Council meeting.

THE ALLEGED OVERCHARGES FOR GAS IN ABERDEEN.

The Sub-Committee appointed by the Aberdeen Town Council, in July last, to consider the subject of the alleged overcharges for gas (to which a number of references has been made of late by our Edinburgh correspondent), have now issued their report. The Committee state that they resolved, in the first instance, to obtain a report from Dr. William Wallace on the quality of the coals used at the Corporation Gas-Works, the gas produced, and the pressure on the distributing mains.* They had carefully considered Dr. Wallace's report, from which it would be observed that he took no exception either to the quality of the coals or the results obtained. They had also examined the pressure-register kept at the gas-works, and found that the pressure agreed with that recommended by Dr. Wallace. With regard to the suggestion that gas of 25-candle power should be manufactured, as the most economical for general use, and the most likely to give satisfaction to all parties, the Committee recommend that this matter should be kept in view, and taken into consideration before the contracts are entered into for next year's supply of coals. The report goes on to say that the Committee also instructed the Gas Treasurer to prepare a statement showing the amount of the gas accounts of consumers resident, for three consecutive years, in each of the following streets:—Causewayend, Market Street, Ferryhill Place, Watson Street, and Frederick Street—the statement to embrace the period from May, 1885, to May, 1888, and to distinguish the number increased or decreased. This statement was duly prepared; and it showed that the increase of gas consumed for the year 1886-7 over the year 1885-6 amounted to 5.08 per cent., while the increase of money paid amounted to 5.3 per cent. For the year 1887-8 the increase of gas consumed over the preceding year amounted to 2.33 per cent. only; while the sum paid for gas for the same period decreased 2.01 per cent.—the price of gas having been reduced. The Committee further find, from the last statement of accounts submitted in connection with the gas undertaking, that the average annual increase of gas consumed since 1872 to the present time has been 10,700,000 cubic feet; whereas the increase of the past year over the preceding year has been only 8,379,000 cubic feet. The gas-rental has decreased from £56,076 in 1887 to £55,604 in 1888. The Committee also received from Mr. Adam Pratt a list of complaints obtained by him in response to public advertisement. The number of gas consumers in Aberdeen is nearly 25,000; and the complaints on Mr. Pratt's list amounted to only 134. Of these cases, an analysis shows the following result:—Number entered twice, 4; number where larger pipes or meters were supplied owing to greater quantity of gas being required, or where pipes were cleaned out or larger burners used, 7; number where gas-stoves were introduced, 2; number where escapes were found ranging from $\frac{1}{2}$ foot to 6 feet per hour, 4; number where no corresponding accounts exist with which comparison can be made, 16; number not found in the Council's books, 4; number decreased in place of increased as alleged, 13. This disposes of 50 of the complaints; and of the 84 remaining cases, it is explained that 5 show an increase on the half year of from 2d. to 1s.; 35, from 1s. to 5s.; 23, from 5s. to 10s.; 15, from 10s. to 20s.; 6, from 20s. to 36s. It is pointed out that, while it is the duty of the Town Council to supply gas of the statutory quality, and keep up the necessary pressure on the street mains, it is the duty of the consumer to use only such quantity of gas as he requires, and that the Council cannot impose any restriction as to the amount which the consumer is to burn. The Committee, in conclusion, take the opportunity of stating that there is not the slightest foundation for the allegation, which, on more than one occasion, has been made in public, to the effect that atmospheric air was being forced through the mains by which the gas supply is distributed to the city.

THE PROPOSED ELECTRIC LIGHTING OF DUBLIN.

At a Special Meeting of the City Council of Dublin last Wednesday—Mr. Alderman KERNAN (*locum tenens* for the Lord Mayor) presiding—the question of the electric lighting of the city was discussed on the estimate of the Finance and Leases Committee coming up for confirmation.

The HIGH SHERIFF (Mr. J. Winstanley), in moving the adoption of the estimate of the Finance and Leases Committee, said that the figures were rather alarming, being £6795, as against £3651—an increase of £3144. The adoption of the electric light would alone cause about £2300 of this additional expense.

Mr. HEALY remarked that in the estimate he could only see a sum of about £1000 accounted for under the head of electric light.

Mr. SHANKS pointed out that there was an estimate for £804 to meet expenses in connection with a loan for £6000 for electric lighting purposes. He was not aware the Council had sanctioned such a loan.

The TOWN CLERK replied that the Council had authorized the obtaining of a Licence, and the necessary expenses in connection with it.

Mr. DAWSON moved a reduction of the amount of the estimate by £1404 made up as follows:—£804 15s. expenses in connection with the electric lighting loan; £500 for maintenance; and £99 less cost of collection.

Alderman O'CONNOR seconded the amendment.

Mr. GILL said he believed the Corporation were going into a thing which would entail an enormous expense on the community. People might say: "Oh, you are a gas shareholder and have no right to speak on this matter." Notwithstanding that he was a shareholder in the Gas Company, he considered himself, as a member of the Council, bound to protest against the enormous expense that was going to be put on the city. The Corporation were rushing into an enterprise the end of which no one saw, and which would saddle the citizens with probably £25,000 of expense. He believed the Gas Company were also going in for electric lighting; but they had some reason of their own. It was not for any profit they would make through it, because he believed both the Gas Company and the Corporation would incur heavy loss. He might point out that in parts of America, where electricity was successful, it competed with gas at from 12s. to 15s. per 1000 cubic feet, instead of 3s.

Mr. DOYLE said it struck him as an anomaly that Mr. Gill, who was a large shareholder of the Gas Company, should oppose this motion, when the Gas Company themselves were about to apply for a Provisional Order for the purpose of enabling them to furnish electric light. His reason for voting for the experiment was that he thought the monopoly of lighting should not be altogether in the hands of the Gas Company.

The HIGH SHERIFF intimated that he would assent to the reduction of the estimate by £1400. It would stop the loan for a year.

Mr. DOHERTY observed that, if they desired to keep up with the times, they were bound to give electricity a trial. Belfast was splendidly lighted with gas; but they had control of the gas-works themselves. If the Dublin

Corporation could not light the city by electricity, they must buy up the Gas Company's property.

Mr. HEALY thought it was singular that this scheme should be attacked at the last moment, and by those gentlemen who were interested in the Gas Company. The increase on the rates of the city by the scheme would not, he asserted, be $\frac{1}{2}$ d. in the pound.

Mr. ROBINSON said that the High Sheriff, who was a Director of the Gas Company, had "let the cat out of the bag" by saying that if they did not vote £6000, they stopped the enterprise for a year. Under these circumstances, he considered that the Corporation, having unanimously agreed to go for a Licence, it would be a monstrous thing to tie up the hands of the Committee now.

Mr. SHANKS said he should support the amendment, as he believed the Committee had exceeded their powers.

The CHAIRMAN said it was not a fact that the scheme was attacked by the shareholders of the Gas Company. He was not opposing electricity for he would like to see the streets of Dublin well lighted, which they were not at present. The lamps were too far apart; and the Corporation were not willing to give money to the Gas Company to light the streets properly.

On a division being taken on the amendment, the voting was equal.

The CHAIRMAN, believing that it was the wisest course for the Council not to press for the money, said he would give his casting vote for the amendment.

Mr. ROBERTSON moved as a further amendment—"That the estimate be reduced by £402 7s. 6d. (instead of £804 15s.) to meet the expenses of a loan for the electric lighting."

Alderman BYRNE, in seconding the amendment, said the Committee could not get the work done for them by a small contractor if the money was not forthcoming for a year. Only a large contractor, who would charge more, could wait out of his money for a year.

After a prolonged discussion, a division was taken; and the numbers being again equal, the Chairman gave his casting vote against the amendment; and Mr. Dawson's amendment, reducing the Committee's estimate to £5400, was adopted.

THE ELECTRIC LIGHTING OF BARNET.

FURTHER DISSATISFACTION WITH THE LIGHTING—THE THIRD COLLAPSE.

At each meeting of the Barnet Local Board of late, the members have been troubled with complaints from the inhabitants as to the lighting of the district by the electric lamps, and last Tuesday's meeting was no exception to the rule. A Mr. Yolland attended and complained that for three nights one of the lights in Park Road had not been alight. The Chairman (Mr. C. Stevens) apologetically stated that the Board "are spending a great deal of time on the subject of the lighting of the town." This, however, did not satisfy the complainant; and he asked that an oil light should be placed in the gas-lamp, to which the Chairman replied: "We must not do that; but we are seriously considering the matter." On being informed that the Board were about to discuss the whole question of the lighting of the district, Mr. Yolland withdrew. A letter was then read from the Board of Trade informing the Board that it would be necessary for Mr. Joel to acquire statutory powers for lighting the district of the Board with electricity; and the Clerk was instructed to inform the Board of Trade; that, under his contract with the Board, Mr. Joel had to do so at his own expense, if it was required. The Board subsequently went into Committee for the consideration of the subject of electric lighting; and, after lengthened discussion *in camera*, instructed the Clerk to give notice to Mr. Joel to remedy the defects in the lighting within fourteen days.

Last Saturday night witnessed the third breakdown of the electric light at Barnet since its introduction. On this occasion the electric light was brilliant from dusk to about 7.30, when it suddenly went out. The occurrence was particularly unfortunate, as the streets were very busy at the time; and numbers of persons resident in the town and in the surrounding villages were engaged in shopping. A thick fog prevailed; and for some time pedestrians were literally groping their way. In the main thoroughfares the inconvenience was not so great, as the lights in the various shop windows served to illuminate the streets to some extent; and particularly so as the lights in question were more numerous than usual on account of shows and window dressings which are common at this season of the year. Even in the most favoured parts of the town, however, it is stated that the inconvenience was considerable; and trade was practically at a standstill for a short time. It was alleged that a wire had been maliciously cut, and the circuit so broken; and, further, that a workman, recently discharged by the contractor, was suspected of the outrage. A more probable explanation, however, is to be found in a letter which the Contractor recently addressed to the Local Board, informing them that he was about to make a change from temporary to permanent engines and plant, and asking to be excused if, in the transition state, any hitch should occur. Whatever the cause may have been, the light was not again available for nearly two hours; and the public, particularly the tradesmen, gave free expression to their annoyance at its failure.

BOLTON CORPORATION GAS SUPPLY.—At the monthly meeting of the Bolton Town Council on Wednesday last, Alderman Miles, Chairman of the Gas Committee, drew attention to the following paragraph in the Committee's minutes:—"Question of supplying gas upon system of monthly collection referred for further consideration. Office Superintendent to obtain information as to the practice of other towns; prepare a scheme for carrying out proposed system; and submit such information and scheme to Works Sub-Committee. The Office Superintendent also to submit report showing the number of deposits and the total amount now in the hands of the Corporation as security for gas supply, and the average yearly interest paid in respect of such deposits." He said that they had 8000 service-pipes laid into houses in and around the district, which had been cut off for one purpose and another, and at present were totally unproductive. It was the desire of the Committee to bring as many of these into use as possible, and under the best system they could organize. They were now getting particulars as to the practice in other towns; and he thought the information might enable the Committee to come to a wise decision on the point. With regard to the deposit system, he had a strong opinion; but if he gave expression to it, it must be understood he did not pledge the Committee or any member of it in any direction whatever. His opinion was that the Committee would do well to abolish the deposit system, except to those people who might be described as "here to-day and gone to-morrow." At the recent meeting of the Manchester Institution of Gas Engineers, Mr. Newbigging wrote in very strong terms against the deposit system; and he entirely agreed with him, believing that the provision had prevented them in Bolton getting a number of consumers they might otherwise have had. In the short discussion which followed, Mr. Broughton said the proposed monthly collection was a most important change, and likely to lead to a great deal of friction, as they could not treat one householder on one basis, and another on a different one. Finally, the minutes were confirmed.

* Abstracts of Dr. Wallace's and the Gas Treasurer's reports were given in the JOURNAL for Aug. 14 last (p. 302).

THE INAUGURATION OF ELECTRIC AND GAS LIGHTING IN IPSWICH.

Public lighting by electricity from a central station was—says the *East Anglian Times* of last Tuesday—quietly inaugurated in Ipswich on Saturday night, when the offices of this paper were brilliantly illuminated from the station in Carr Street, not far from the spot where, 66 years ago, public gas lighting was first commenced in the town. The coincidence is singular; the premises in Carr Street, taken as a central electric lighting station, being but a few yards from the site of Messrs. Ransomes' old premises, where the gas lighting of Ipswich was started. The house is still marked by a gas-lamp—the very first to be lighted. A little party assembled on the occasion, 66 years ago; and one of the elder Ransomes had struck a light to ignite the first public gas-jet in Ipswich, when Mr. Richard Ransome dashed forward and declared that the new light should not be started in such a way. Wiping up a one-pound note he set fire to it; and thus was public gas lighting inaugurated in Ipswich. Mr. Dykes Alexander was the first Chairman of the Company, which comprised eighteen other Alexanders, six Cobbolds, twelve Ransomes, eight Browns, three Maws, Mr. Arthur Biddell, Mr. D. P. Goddard, Mr. W. Haldeman, M.P., and Sir W. Fowle Middleton, who, imitating his famous predecessor, the author of the New River, took a large interest in the new light. The famous Engineer, Sir William Cubitt, then an undistinguished young man, was the first Engineer and Clerk to the Company, at a salary of £100. It may be interesting to mention that the rental during the first nine months from private consumers only amounted to £514 7s. 8d.; and that the Company earned 5 per cent. from the first. The Committee in their first report "flattered themselves" that the undertaking "would prove satisfactory to the proprietors." That it has done so is beyond doubt; that it will continue to do so both for light and heat is the general belief. The inauguration of electric lighting on Saturday in Ipswich was not marked by the sensational destruction of a one-pound note. It was quietly done in the back yard of the premises taken as a lighting station by Messrs. Lawrence, Paris, and Scott, Limited. The old house where gas was started will soon be replaced by a brand new building; and after 66 years the gas-lamps of Ipswich are menaced by a brand new light. This also is a young giant, born near the self-same spot which gave birth to gas lighting. The *modus operandi* consisted of a big portable engine, put into the central station by Messrs. Ransomes, who are to the front in electric lighting, as they were in gas. This engine drove a dynamo, fixed by Messrs. Lawrence, Paris, and Scott, and which ran so smoothly that it was difficult to see any motion existed. The electric current was then experimentally conveyed to the *East Anglian* offices, where about half-past ten o'clock all the lights were set going. The *East Anglian* makes its own electricity. We are bound to admit that the light supplied by the new Company was whiter and steadier than ours—steadier because there was no machinery to be turned, only light to be produced. The engine power at the lighting station in Carr Street will, it is expected, soon prove inadequate for the anticipated consumers of the light, by which time a cable will be laid to the Orwell Works; and with the engine power at that famous establishment all Ipswich might readily be lighted.

GASEOUS FUEL AND ITS USES.

At the Meeting of the Halifax Literary and Philosophical Society last Tuesday evening, Mr. B. H. Thwaite, C.E., F.C.S., delivered a lecture on the above subject. He commenced by referring to the incalculably evil effects of smoke production on health, and the extraordinary waste resulting therefrom; and stated that no remedy, except the use of gaseous fuel, would be effectual in removing the evil. Alluding to the extraordinary development of the application of natural gas in Pennsylvania, the lecturer pointed out that, from geological premises, he was of opinion that some 1500 feet beneath the salt-beds of Cheshire and other salt districts in this country, natural gas might be found; and, had we had the enterprising spirit of the Americans, not only the salt-fields but the coal-fields of this country would have been prospected and drilled ere this. The scientific processes involved in the generation of gaseous fuel from coal and oil were described, and Mr. Thwaite showed a scheme for supplying gaseous fuel to London from the South Wales, Staffordshire, and South Yorkshire coal-fields. The mains would be four in number from Staffordshire, for a length of 120 miles. The South Wales branch main would consist of two pipes, 100 miles in length; and the South Yorkshire branch, one pipe of 70 miles in length. Branch pipe-lines would supply all the principal towns between Barnsley, Stafford, and London. The coal would be converted into gas at the coal-fields, and delivered to the mains under great pressure; and could be distributed in the towns in the daytime for heating purposes by the ordinary mains, and could also be used at night with special burners for illumination. The saving in fuel by this distribution system would, he asserted, be colossal. There would be no cartage nor railway carriage. The gas would flow from its source to the position of use. There would be no middlemen. The saving in London alone would realize an immense figure; and the smoke question would be settled once for all, with a benefit to the inhabitants of this country that would surpass the effect of all the great achievements of sanitary and economic science. Mr. Thwaite pointed out that natural gas is conveyed 60 miles from the wells in Pennsylvania to distributing locations, and that within the last few years the length of distributing pipes has increased from *nul* to 2300 miles. The lecturer gave a description of a scheme for conveying gaseous fuel to the large towns in Lancashire from the Wigan coal-field; and in the West Riding of Yorkshire, from the Barnsley coal-field.

LINCOLN CORPORATION GAS ANNUITIES.—At the last meeting of the Lincoln Town Council, it was determined, in pursuance of the powers contained in the Lincoln Corporation Gas Purchase Act, 1885, "to pay off and redeem all the annuities secured by gas certificates under that Act, at the price of 25 years' purchase of such annuities."

THE NORTHERN COAL TRADE.—The coal trade of the north-east of England has shown ease, on the whole, during the last few days. The steam coal trade has been affected by the closing of some of the Baltic ports, and the shipments having been less; and the price has been a little lower. From 8s. 6d. to 9s., less discount, may now be put as the price of best steam coals, and second is correspondingly lower. Small coal is almost a drug in the market, and sells at very low prices. For gas coal, there is a very full demand; and the chief collieries find it difficult to obtain all that is needed to supply the orders that have accumulated. The price of gas coals varies very greatly; but about 7s. 6d. is the quotation for best qualities and for odd cargoes. Many of the collieries are behindhand in their deliveries on contract; and it is probable that advantage will be taken of the next few weeks, when the miners usually work fuller time before the holidays, to make up arrears. But the high rates of freight asked for the conveyance of coals to the Metropolis tell against larger deliveries, though the rates of freight are slightly easier than a few weeks ago. This, however, may be changed by a storm at any time. The manufacturing coal trade shows firmness.

DIVINING FOR WATER AND METALS.

In another part of to-day's issue, we give an account of a meeting called last Saturday week for the purpose of testing the claims made on behalf of certain so-called "water diviners"—about which we had something to say a month or two ago in our leading columns. Our lively contemporary *Truth* also had a representative at the meeting; and the account he sent in of the proceedings is prefaced by the following editorial remarks:—"As the use of the 'divining-rod' for discovering subterranean water and metals has been very much pushed lately by parties interested in the business; and as I have more than once expressed my disbelief in the process without reserve, I was much gratified the other day at the receipt of an invitation from Mrs. Louise Cotton to witness experiments with this said rod by several gentlemen of established reputation in the art or mystery of divination by that means. Captain Nisbet, an Elder Brother of the Trinity House, said the invitation, had kindly lent his house and grounds ('Hollywood,' South Kensington) for the occasion; the grounds being specially adapted for the purpose by the presence of an old well and spring, long covered over, the exact site of which was known only to the Captain, who was 'quite sceptical as to the powers of the rod.' Being, unfortunately, prevented from attending the proceedings myself, I deputed a fairly intelligent member of my staff to represent me. I think I cannot do better than print his report in full, for the benefit of all who take an interest in this form of black art, believers and unbelievers alike." Here is *Truth's* report:—

On arriving at Captain Nisbet's, I found the four professed "diviners" who had been announced to attend already on view, divining-rods and all, in the drawing-room; and a move was shortly afterwards made to the garden—Mrs. Louise Cotton (if I may be forgiven the expression) "bossing the show." The four diviners present were: Mr. W. Scott Lawrence, of Bishopston, Bristol, described to me as "stone merchant"; Mr. John Stears, of Hnll, described as "gas engineer, &c.," Mr. Charles Holt, of Redmill, Bottesford, Leicestershire, signalman on the Great Northern Railway; and Mr. Alfred Allen, of Abergelle, North Wales, who was introduced as a "farmer's son."

It was arranged that one of the diviners should commence operations while the other three remained indoors, out of sight of the garden. The first innings was accorded by acclamation to Mr. Lawrence, as the senior professor present. Mr. Lawrence's name may be in the recollection of some of the readers of *Truth*. He it was who was retained not many months ago by the Tiverton Town Council to advise as to the locality in which wells should be sunk for the borough water supply. *Truth* took the liberty of commenting freely on the extraordinary hoops-pocus gone through on that occasion; and Mr. Lawrence took the liberty of replying with equal freedom in a letter, which I think was published, rebuking the scepticism which ridicules things passing its comprehension. I may say at once that Mr. Lawrence is not only the *Doyen* of the divining profession, but that he was by far the most interesting figure present on Saturday. He owned to 79 years of age, but did not look it; being ruddy and clear complexioned, hale, hearty, and strong on his legs. In general figure—at any rate with his hat on, and a fringe of white hair curling luxuriously underneath it—he might have passed for a country cousin of Sir John Bennett.

Before I describe what Mr. Lawrence did, it should be understood that Capt. Nisbet's is an old-fashioned, rambling house, the presence of which in the year 1888 within a mile of South Kensington station is quite as near an approach to a miracle as anything else which I saw on Saturday. The garden might be half-an-acre in extent, chiefly consisting of a large lawn, with a winding gravel path all round it. At the further end were one or two greenhouses and outbuildings. Somewhere on the premises, we were told, was an old well, from which the house was still supplied. The precise spot, however, we were assured, was known only to Captain Nisbet, and to no one else present; and I may say here that Captain Nisbet's *bona fides* on this point was, in my opinion, beyond question. He was announced as a sceptic; and I left him still professing scepticism when I came away.

Now for Mr. Lawrence. He rather disappointed us at starting by announcing that he could not undertake to find the well itself, but only the spring which supplied the well—the divining-rod being only susceptible to *running* water. However, as the spring must run into the well, this was not really so much like hedging as it looked at first sight. With this preface, the wizard took his rod in both hands, and commenced to pace the garden with measured tread and an air of intense preoccupation. The rod was a tolerably stout hazel twig shaped like the letter Y. Mr. Lawrence grasped one arm of the fork tightly in each hand, palms uppermost. The straight stem was pointed away from him, and the arms of the fork bent outwards. The intelligent reader can soon ascertain for himself that a forked twig held in this fashion acts like a spring. The apex has a constant tendency to spin round—greater or less, of course, according to the degree of tension at which the thing is held; and a more or less considerable effort is consequently required to keep the stem pointing horizontally. Mr. Lawrence appeared to steady it by pressing his elbows tightly against his sides.

Well, he started from the corner of the garden nearest the house, and walking diagonally across the lawn, struck the path on the left-hand side about half-way down. (I must apologise for these details; but they are necessary for the correct appreciation of the result.) From this point Mr. Lawrence followed the path down to the bottom of the garden, and right round to the corresponding point on the opposite side; the spectators attending with breathless interest. The circuit of the lawn was not quite completed; for, having reached the point opposite where he had first struck the path, Mr. Lawrence turned on to the grass again, and made for the path in front of the house, which he had missed at first starting. The kitchen and offices were evidently in this direction; and at the corner was a screen apparently shutting off a yard. Passing this spot, the path ran past some rockwork—on both sides, if I remember rightly. Suddenly, as the rockwork was reached, the rod flew up in Mr. Lawrence's hands. He stopped and fell back a pace. The rod was now up in the air jibbing and gyrating, and apparently trying to throw Mr. Lawrence down. The old gentleman, however, stuck to it manfully. His hat fell off; but still he wrestled and writhed, spluttering with his lips at the same time, till at last the rod snapped in two. Mr. Lawrence staggered backward, with his eyes closed, into the arms of one of the spectators; and an enthusiastic cheer went up from the assemblage. Having come round, which he did in a moment or two, the wizard crossed the magic spot without his wand, and then proceeded to approach it from the other side, in order to fix the locality exactly. This time, however, instead of the divining-rod, he produced a piece of steel spring, which he held between his hands, much in the same fashion as the rod, compressing it into the shape of a bow with the convex side away from him. As he approached the same spot, the steel spring behaved in precisely the same fashion as the wooden rod; and after a similar struggle with it, Mr. Lawrence desisted. He next took soundings, as it were, across the lawn with similar results; and he finally announced that there was running water under this part of the garden, in a line drawn about parallel to the house, through the spot where the first manifestation occurred.

I describe all this minutely, partly for the sake of the inference (of which presently), partly to avoid going in detail into the performances of the other artists, which were generally similar, but tame and insignificant after Mr. Lawrence's exhibition, for the simple reason that in the other cases the agitation began and ended with the rod, and did not communicate itself to the operator. I may here remark that, in a conversation which I had with Mr. Lawrence, he attributed his "convulsion" (as one critic aptly termed it) to the infirmity of age, and his growing inability to cope with the potent agencies actuating the rod. He has only been taken this way, it seems, in recent years.

Of the other performers, Mr. John Stears was by far the most capable, if a diviner is to be judged, as I suppose he should, by the quantity of water he can discover in a given space. Mr. Stears was a somewhat fallow-faced and very talkative gentleman, with a sandy beard; and I should guess his age at about 45. He used a much less substantial rod than Mr. Lawrence, and held it point downwards. He had not gone a yard from the spot where we started the Bristol gentleman, before his rod was on the jump. He did not follow the path; but wandering more or less aimlessly down the garden, he spotted the subterranean fluid in at least half a dozen places, several of which had been traversed by his predecessor without so much as a tremor. By this time a large number of the visitors had armed themselves with divining-rods or steel springs, and were wandering about the premises trying their luck. A Mrs. Balfour (announced as a "lady diviner") had, if I remember rightly, also taken a hand, and had confirmed Mr. Lawrence's discovery of water in the neighbourhood of the house. It was now getting dusk, and the two remaining professionals, concluding, I suppose, that they had been forgotten, appeared on the scene unsolicited and commenced divining on their own account. I took a turn with each of them. Mr. Holt was an unobtrusive young man, who went to work very rapidly in a stooping position, with the point of his rod close to the ground. On Mr. Stears asking him presently whether he could not work as well upright, he said that he had never tried. He *did* try, however, then and there, and seemed to find the result equally satisfactory. The last artist, Mr. Allen, was a youth of stolid countenance and the general demeanour of the comic countryman. He held his rod between his fingers, with his hands hanging down before him. When he got a bite, the rod just squirmed between his fingers; but he said that sometimes the motion was strong enough "to take the skin off you." The only time Mr. Allen showed any sign of excitement was when he came presently to see Mr. Lawrence "convulsed," at which he burst into a loud bucolic guffaw. I conclude from this that the modern haruspex has less command of the risible faculty than his classical prototype.

But now a few words about a different experiment—to my mind the only one of any practical value. The divining-rod, it may be as well to state, is capable (in the hands, of course, of a performer possessing the requisite gift) of indicating the whereabouts of metals and certain minerals, as well as water. Mr. Lawrence has no gift for metals; but Mr. Stears is as good at one as the other. The most remarkable feature, indeed, in his performance was that when his rod scented metal, the point spun round towards him, while to indicate water it revolved in the opposite direction. He demonstrated this conclusively by holding it towards various pieces of metal-work. Occasionally the presence of metal under Captain Nisbet's lawn was indicated in this manner. On Mr. Stears attributing this to metal pipes, some one asked what would happen if there chanced to be running water in the metal pipe; but on this point Mr. Stears appeared uncertain. Well, it was arranged that this gift of Mr. Stears's should be tested by some more convenient method than digging up Captain Nisbet's lawn to look for the metal, and an experiment was arranged by a select committee consisting of Mr. Frank Podmore, Hon. Sec. of the Psychical Research Society, Mr. W. Webber, and myself. We went indoors, and deposited five sovereigns (Mr. Stears having expressed a preference for gold) inside a bulky volume, which was laid on a small billiard table. Four other books were also laid on the table; and Mr. Stears was then called in to try and find metal. He went round the table with the rod, talking a good deal, and got a decided indication of metal long before he came to the gold. He drifted on; and it is right to state that on the first round the rod pointed for metal over, or very nearly over, the book which contained the sovereigns. It did the same thing, however, in several other places; and Mr. Stears remarked that he felt he was getting a little tired. Mr. Podmore then told him that there was metal under one of the books, and asked him to make a choice between them. He again went round, getting decided indications at the corners and sides where somebody had remarked that the brass mounts of the pockets would be (the table, I should state, had a cloth over it). He now passed without a sign over the five sovereigns, which were at the top, and finally got a decided manifestation from the rod over the book at the bottom, for which he plumped accordingly. A more ignominious fiasco I never saw. Apparently Mr. John Stears was somewhat of the same opinion; for, on being shown the five sovereigns in the book at the other end, he disappeared without further remark. I omitted to mention, by-the-by, that while Mr. Stears was passing the rod to-and-fro over the table, and showing that there was metal in some places and none in others, a clergyman present observed that it was desirable to mark the place indicated. For this purpose he placed a small purse on a spot where Stears was showing us that there was no metal. The rod immediately shied. "Ah!" said Stears, "that shows the money in the purse." When he was gone our clerical friend produced the purse—a brown leather article with an elastic band round it—and informed us that he had carefully emptied it before laying it on the table, so that there was not a particle of metal about it.

I am compelled to pass very briefly over the rest of the proceedings, including Mrs. Cotton's interesting paper on divining-rods, the motive power of which she was inclined to regard as either electricity, animal magnetism, or "astral fluid." Neither have I space for the subsequent discourse of the professors—for Mr. Lawrence's account of the surprising things he has done during the 50 years or more that he has been in active practice as a diviner; nor for Mr. Stears's story of how he fixed the locality of all the gas-pipes in Portadown, the position of some of which was unknown even to the Gas Company, and how he had been invited to go through South America prospecting for metals—in the interests, I presume, of "Bull" operators at home. I must pass to the net result of the practical experiments.

And, first, for Mr. Lawrence. This gentleman, as I have said, discovered running water in one corner of the garden, and in his case alone, among the whole party, had we indubitable evidence of the soundness of the divination. To the left of the spot where Mr. Lawrence was first "seized" stood, on an abutment of the house, an unmistakable water-tank. To the right of the same spot, in the rockwork already described, was a hydrant for the purpose of watering the garden. From the tank to the hydrant there ran a water-pipe; and within a yard or so of the spot where it might be presumed that this pipe passed under the gravel path, Mr. Lawrence became convulsed. What the peculiar gift was which enabled Mr. Lawrence to divine the presence of this particular running water, I leave to the intelligence of every reader with a head upon his

shoulders. In point of fact the thing was so transparent that, immediately after Mr. Lawrence's demonstration, some sceptic went and laid a piece of sacking over the hydrant. Next, Mr. Lawrence located the same spring in a line running from the hydrant parallel to the house. Over this line he had himself gone at starting without discovering anything. On the other hand, I had it from Captain Nisbet that the pipe supplying the hydrant ran in a straight line diagonally across the lawn to the greenhouse at the opposite corner of the garden. This line, Mr. Lawrence crossed twice in his perambulation; yet he never found water until he had spent five minutes reconnoitering the premises, and had the hydrant right under his nose. I may say further that, so far as I was able to observe, not one of the other "diviners" gave the slightest indication of the line of this pipe—not even Mr. Stears, who had a double chance with it, inasmuch as it was a metal pipe with water inside it. Yet observe that Mr. Stears and the others (always excepting the circumspect Lawrence, who is clearly a very old hand at this business), while they passed over the only known running water on the premises, professed to find water in half-a-dozen places where there was not the slightest means of testing the divination. Even in these places there was no agreement whatever among them, except when they met face to face, or when they had had every opportunity of observing one another. Lastly, as to the well. The well was situated, so Captain Nisbet informed me, about half-way between the middle of the lawn and the path on the left-hand side. Considering that water was pointed out in at least a dozen places under that garden (Stears, indeed, seemed inclined to think that the subsoil must be riddled with drains, which, however, Captain Nisbet denied), it is difficult to say of any particular spot that water was not indicated there. To the best of my belief, however, not one of the four diviners pointed out the site of the well. I will go further than that, and say that not one of them pointed to any line of running water which is at all likely to be that of the spring feeding the well. Certainly neither Holt nor Allen did; certainly Lawrence did not, though he made the circuit of the garden and passed within a yard or two of the well itself. Concerning Mr. Lawrence's marvellous performances elsewhere during the last half-century I will at present express no opinion, nor about those of any of the other diviners, though I have an opinion on the subject, and a very strong one. But so far as the experiments of last Saturday went, I say, without hesitation, that a more contemptible display of transparent humbug was never palmed off upon the credulous dupes of "occult science."

THE PROPOSED MODIFICATION OF THE THIRLMERE WATER-WORKS SCHEME.

THE LATE CHAIRMAN OF THE WATER COMMITTEE ON THE PROPOSAL.
Mr. J. Grave, late Chairman of the Water-Works Committee of the Manchester Corporation, in a letter to the local papers last Tuesday, "enters the lists" against the Act which the Manchester Corporation are about to promote, to give them power to make certain deviations in the line and levels of the aqueduct from Lake Thirlmere to Prestwich, and references to which appeared in the JOURNAL last week (pp. 987, 993). He says that a more dangerous and suicidal measure could not be conceived than one which at once practically reduces the quantity of water to be taken from Thirlmere from 50 million to about 10 or 12 million gallons, leaving unappropriated about 40 million gallons per day, which might be claimed, as unnecessary for Manchester, by other communities. The first pipe, he states, will cost about £1,700,000; and the remaining pipes would only entail an additional expenditure of about £340,000 for each. It is as well, the writer continues, to look at the consequences which would follow this new Act if only one pipe is laid. They will be forced to keep the old price when (even with an additional 10 million gallons of supply) it could have been reduced by one-half the present charge to Manchester, and still have had an additional extra revenue of thousands, besides paying interest. He also calls attention to the extra cost which would be entailed in opening the ground to lay additional pipes should they be required in the future, when, at a very small cost, more pipes could now be laid. Mr. Grave expresses satisfaction at finding that the Lake Association are objecting to the Corporation making a road only on one side of the lake, in place of the one that goes all round the lake, at the proper level ordered by the old Act of Parliament. "Let the public adhere to the old Act, and the Corporation cannot get out of it; and why should they?" The roads are all on their own land, and will, the writer asserts, make the whole of the 11,000 acres which they now hold much more valuable and accessible. These roads will cost £35,000 (the surveyor's estimate). But £20,000 will be required in any event, to heighten the main road above Thirlmere to Dunmail Raise; leaving only £15,000 to complete. The proposed Act, in Mr. Grave's opinion, is a "serious mistake, and should be abandoned." It will endanger the old powers that cost so much to get, as well as break faith with those in the district who assisted Manchester so manfully in the late contest in Parliament; and if the Act passes, he should "feel personally dishonoured." Glasgow, he continues, is bringing in 60 million gallons of water in addition to its present supply. The proposed Act may limit the extra supply of water to Manchester to 10 or 12 million gallons; and the result will be that Glasgow will get all the Manchester bleaching trade, although handicapped by railway carriage and sea freight. Concluding, Mr. Grave says that he shall wait with some curiosity for the result of the meeting of the Council and the confirmation by the ratepayers of the intended Act. He repeats that he considers the Act quite unnecessary, and one which will involve, even if unopposed, an expenditure of more than £4000.

MEETING OF RATEPAYERS.

A Meeting of owners and ratepayers of Manchester, convened by a requisition presented to the Mayor, was held last Wednesday, in the Town Hall, for the purpose of consenting or otherwise to the promotion by the Council in the next session of Parliament of the Bill referred to above. The Mayor (Mr. Alderman Batty) presided; and there were a large number of members of the Corporation and other citizens present.

The Mayor moved—"That this meeting consents to the promotion by the Council of the City of Manchester in the next session of Parliament of a Bill, the short title of which is intended to be 'The Manchester Corporation Act, 1889,' . . . such Bill to be promoted out of the public funds or rates in the hands of the Corporation, or hereafter to accrue to them on water-works account, or out of moneys to be raised under the authority of the intended Act, or otherwise out of such public funds or rates as the Corporation may determine." He remarked that the alterations which it was proposed to make in the plans for the construction of the Thirlmere works would not in the least injure the scenery; but make it better than would have been the case if the original plan had been adhered to.

Alderman Sir JOHN HARWOOD, in seconding the resolution, adverted to some of the points of objection raised in Mr. Grave's letter. Mr. Grave, he said, regretted that the Committee were not in favour of bringing the 50 million gallons of water per day from Thirlmere which the Act of Parliament empowered them to do. The answer to that objection was not far

to seek. In going to Parliament for a Bill for the promotion of any public work, Parliament insisted on knowing the maximum amount of work that was contemplated. It would not do to ask for a small Bill, and then desire something greater. The next complaint was that if the Council only brought in 10 million gallons, they would be obliged to maintain the present price of water. He thought they might be thankful that it was not intended to bring from Thirlmere the 50 million gallons; for if they did bring so much, they could not continue the present price of water. According to Mr. Grave's calculation, the 10 million gallons would cost £1,700,000. This showed that Mr. Grave's memory must seriously have failed; for that was simply the cost of the water. Mr. Grave utterly ignored the cost of the watershed—11,000 acres—the cost of the wayleaves, and interest on money—amounting to at least £2,400,000. Mr. Grave went on to say that each subsequent pipe would cost the city £340,000; and there again he was afraid that Mr. Grave was very much mistaken. The scheme for the sanction of which the Corporation in the first instance applied to Parliament was a scheme for all time; but when they came to develop it, they found that, by modifying the provisions of the Act, by raising the embankment of the lake 20 feet instead of 50, they could save a great amount of expense, and provide for all the requirements for a long time to come. Considering also the storage they had at Longdendale, and the fact that the Woodhead works had cost £3,500,000, no sensible man would dream of bringing 50 million gallons of water from Thirlmere, especially when it was remembered that the water at Woodhead stood third in quality of any water in the kingdom. It would be a most suicidal policy. They might estimate that the cost of laying the pipes, &c., would be £340,000 per 10 million gallons of water. Why, then, should the Corporation incur an extra cost of £340,000 per 10 million gallons for the 40 million gallons they did not at present require? The capital charge—viz., four times £340,000—would be £1,360,000; the annual charge in respect of interest at 3½ per cent. would be £47,600; and the annual charge in respect of sinking fund, on a 70 years' basis, would be £4707—making a total annual charge of £52,307, which was equal to a rate of 5½d. in the pound. The sum of £52,307, accumulated annually for 20 years at 3½ per cent., would amount to £1,479,225; and that represented the saving to the city by not making the four additional pipes until 20 years had expired. No sensible man would bring water into a city, which was not wanted; and it would be monstrous to suppose that an intelligent community like Manchester would have gone to Thirlmere, in face of the opposition they met with and the sentimental feeling raised against them, except as an absolute necessity. But for that necessity there would be no justification for disturbing one of the most beautiful and invigorating districts in the United Kingdom. He pointed out that, by raising the lake to the full height, it would submerge and render valueless the whole of the flat land now utilized for farming purposes, and from which a rental of about £2000 a year was received. This might be saved—certainly to the extent of £1000 a year—for at least 20 years, by only raising the lake 20 feet; and a rental of £1000 a year for that period at 3½ per cent. compound interest would amount to £28,279. He had received a memorial from the Lake District Defence Society and the Commons Preservation Society on the proposals contained in the Bill the Corporation were promoting; and it was most satisfactory. It was the desire of the Committee that sudden alterations affecting the beauty of the district should not be made, but that they should carry out the work step by step.

The resolution was put and carried unanimously; and a vote of thanks to the Mayor concluded the proceedings.

THE BRISTOL GAS AND WATER UNDERTAKINGS.—Mr. H. J. Williams has given notice of his intention, at the next meeting of the Bristol Town Council, to move the following resolution:—"That a Committee be appointed to consider and report as to the advisability of the Corporation acquiring the undertakings of the Bristol Gas Company and the Bristol Water-Works Company; and if it appears to such Committee advisable that such undertakings, or either of them, should be so acquired, to endeavour to ascertain upon what terms such acquisition can be effected."

THE PUBLIC LIGHTING OF FELIXSTOWE.—On the evening of the 29th ult., the streets of the rapidly-increasing town of Felixstowe were for the first time successfully lighted with gas. There are 58 ordinary lamps; and two of Messrs. Sugg's "Victoria" lanterns. Each lamp is fitted with one of Borradaile's metallic governors, consuming 5 cubic feet per hour. The Gas Company light, extinguish, clean, and keep in repair all the lamps, at £2 2s. each; the lamps burning 1000 hours during the six winter months, commencing with October. For every extra hour after 1000, ½d. is charged. The whole of the columns, lanterns, and fittings were supplied by Messrs. R. and J. Dempster, of Manchester.

THE WATER SUPPLY OF QUEENSBURY, NEAR BRADFORD.—Last Saturday week the new water supply for Queensbury, obtained from the Bradford Corporation, was for the first time turned on for public use. Owing to the elevated situation of Queensbury, considerable difficulties have stood in the way of providing an adequate supply for the district; but some time ago the Local Board concluded negotiations for this purpose with the Bradford Corporation, whose reservoir at Thornton Moor stands on a sufficiently high level to supply the whole district (except a portion of Mountain) without resort to pumping. The Halifax Corporation possessed rights extending over about two-thirds of Queensbury; but, owing to the low level of their supply, they decided to waive them in favour of the Bradford Corporation. A Local Government Board inquiry was held in due course; and the Board received sanction to borrow the necessary money for carrying out the works. Altogether it is computed that 7½ miles of pipes have been laid; the connection between the Bradford pipes and those of the district being made near Black Diko Mills. As already indicated, the supply is derived from the Thornton Moor reservoir of the Bradford Corporation, which is situated 1241 feet above the level of the sea. The Local Board, however, intend to construct a storage reservoir of their own at Mountain, on a level about 30 feet lower, and capable of containing 2,000,000 gallons. The number of houses, farms, &c., supplied by the new service, excluding the portion of Mountain before referred to, from which no applications have been received, is 1477; and with the quantity of water required by the mills, the daily consumption is estimated at about 110,000 gallons. The cost of the whole scheme is expected to be about £6500—£3350 for the service-pipes, &c., and £2811 for the reservoir. Mr. John Drake, the Engineer to the Local Board, prepared the plans, and has superintended the construction of the works. The testing of the mains has proved very satisfactory; and the water is now regularly on for general use. At the meeting of the Queensbury Local Board held last Wednesday, it was resolved that consumers of water in excess of 2,500,000 gallons per quarter be charged 9½d. per 1000 gallons (being a reduction of ½d. per 1000 gallons) for all water consumed above the said quantity. A letter was read from the Surveyor of the Thornton Local Board inquiring if the Board would supply water at Laundeside and West-choles, in the district of Thornton; but it was pointed out that they could not do so without the consent of the Bradford Corporation.

NOTES FROM SCOTLAND.

(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The proposal by the Edinburgh and Leith Gas Commissioners to reduce the price of gas for public lighting virtually from 3s. 3d. to 2s. 6d. per 1000 cubic feet was this week before both the Town Councils of Edinburgh and Leith. In Edinburgh, where the step has been taken with a view to giving more light in the streets, there will be a slight increase of charge. There are, Bailie Steel stated, 9180 lamps in the city, of which 6708 are fitted with No. 1 burners; 2155, with No. 2 burners; and 317 are Bray lamps. It is proposed to supply all the ordinary lamps with No. 2 burners. In Leith, Bailie Garland informed the Council that, by the reduction, they would save £200, which would be the first instalment of the benefits of the gas purchase. This, I venture to think, was an injudicious remark. As he went on to show, there are 1766 No. 1 burners in use, and only 184 No. 2 burners; and, only the other day, Bailie Archibald stated at a Gas Commissioners' meeting that Leith was worse lighted than Edinburgh. The necessary improvement of the lighting will thus probably absorb the £200 of saving contemplated by Bailie Garland.

Dundee has by Royal Warrant been raised to the dignity of a city; and its Chief Magistrate will henceforth bear the title of Lord Provost. The Gas Commissioners, at their meeting on Wednesday, congratulated Lord Provost Hunter on his new honour. There was very little business before them. It was reported that an annuity of £11 10s. had been bought in for £345. The Commissioners approved of the transaction, which was surely effected at a high price; being at the rate of 30 years' purchase. It was also reported that the visitors to the works had received "renewed explanations from the Manager, which were entirely satisfactory." This, no doubt, refers to the matter of using air in the process of purifying. The explanations have not been made public, which, in one sense is to be regretted, because the person, or combination of persons, whom I mentioned last week as giving trouble to the Commissioners in connection with this matter, are resolved not to let the subject out of mind. This week, an anonymous letter-writer, styling himself "Light," says:—"The gas is much better now than it was when I wrote you first about it. There is not so much air in it now; the light is much clearer; and the air in the house is much more pure when the gas is burning than it was before. 'Scrutinizer' says there are coals that only produce 7000 feet per ton. That is true, but they are not real gas coals, but a mixture. They produce as much soot as gas. The Commissioners charge us 3s. 8d. per 1000 feet, that is £1 18s. of the ton of coals for gas, besides what they get for all the other refuse. I think they might let it down to 3s. 6d. per 1000 feet." I cannot help thinking that whoever is responsible for this outcry—it is not worth the name of "agitation"—has a grievance against the officials of the Gas Commissioners; and from recent circumstances, as well as from frequent expressions in the letters with reference to the quality of the coal used, I should not be surprised to find that the grievance has reference to the coal contracts. This, of course, is only a surmise. It is evident, however, to everyone who peruses the letters, that they are written by persons who are familiar with much that goes on within the gas-works; but that, on the other hand there is much in gas-making with which the writers are not conversant. One cannot but sympathize with the Commissioners and with Mr. McCrae, in being bothered by a persistent cry of a catchpenny order like this, got up so as to affect, and presented only in such a way as to affect, the ignorant. Were the authors certain of their conclusions, they would take steps to bring them before a class more competent to judge of them than is the general newspaper reader, as well as to back up their views with something which would show a reason for their existence. They do not do this, probably because they know how futile it would be to attempt it; but it is a pity that the Commissioners, when they had once admitted the subject worthy of their consideration, did not put up one of their number to give such explanations as would have been understood by the public. The explanations which were so convincing in the case of the visitors, surely would not have been thrown away upon the public, if repeated to them.

I am afraid the Aberdeen Sub-Committee, whose report is given in another column, have misunderstood the charge which was preferred against them, or, perhaps, to put it milder, they have only dealt with a portion of it. What was complained of was that, although the price of gas had been reduced, individual gas bills had risen; and the Committee were asked to explain how such a state of affairs could arise. This matter they have disposed of; and they have done it satisfactorily, as I expected they would. They have shown that there could have been no general policy such as was averred, because the consumption of gas and the relative charge year by year has shown a proper co-relation. But that is all they have done; whereas there was, although not perhaps a direct accusation, an innuendo that, in what they did, they were acting dishonourably. Perhaps, with the characteristic long-headedness of Aberdonians, they have concluded that, there being no foundation in fact for the allegations, there could be no question of their honour; and, strictly speaking, that would be a correct assumption. The Committee, however, would have done themselves no harm had they gone further, and left no ground for even a whisper of doubt as to the thoroughness of their acting. For instance, the quality of the coal used was called in question; and to settle this matter, a report on the subject was procured from the late Dr. Wallace, of Glasgow. But Dr. Wallace's report was impugned on the ground that he did not visit Aberdeen and personally inspect the coal at the gas-works. This was but a covert way of stating that although, on paper, the coal was all right, in reality that might not be found to be the case. Now the Committee could have met that by a clause in their report stating that they had examined the invoices for coal, and had found that it was all in terms of the contract. Such a statement would have settled the matter in the minds of all reasonable persons.

At the meeting of the Aberdeen Town Council on Monday, the Gas Committee recommended that eight of the existing purifiers should be enlarged. The purifiers are old and incapable of passing the winter output satisfactorily. It is proposed to make them similar to several which the Committee already possess, at a cost of £1500, of which £1000 is provided for in the estimated revenue of the current year.

At the meeting of the Stirling Water Commissioners on Tuesday, it was reported that the recent extension of the water system to Bannockburn had cost £1550.

The great scarcity of water experienced at Kinghorn during the past two seasons, and an unfavourable analysis by Dr. J. Falconer King, of Edinburgh, in June last, as well as pressure from the Board of Supervision, led the Kinghorn Town Council recently to consider the question of an additional water supply for the burgh; and they have now resolved to adopt the scheme prepared by Mr. D. Meuzies, C.E., of Edinburgh. This is the third supply of water introduced to the town within the past twenty years. The total cost of the undertaking will be considerably over £2000; and operations are expected to commence shortly.

The refusal of the Carron Iron Company to pay the domestic water-

rate which has been imposed by the Falkirk and District Water Trust, until the pipes are laid (which I noticed in my "Notes" last week) was before a meeting of the Trust on Monday; and it was agreed to request the Law Agents of the Carron Company to consent to the question at issue being submitted to the First Division of the Court of Session by a special case mutually stated. Meantime instruction was given to obtain the opinion of Counsel on the subject.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.
Ex-Bailie Crawford, a leading member of the Glasgow Corporation Gas Committee, had occasion last night to address his constituents of the Tenth Municipal Ward, as he was unable to do so when the Ward meeting was held prior to the annual election at the beginning of last month. From the prominent position which he has acquired in connection with the administration of the local Gas Act, it was but natural that he should have something to say on gas affairs. He said, in the course of his remarks, that he had been reproached for reducing the illuminating power of the gas. This reduction of the illuminating power had, however, relieved the Gas Trust from the tyranny of a ring of coalmasters who were possessed of the coal necessary for the production of the higher quality of gas; and the relief had resulted in a saving of £30,000 a year to the citizens of Glasgow. As to the Gas Stove Department, he remarked that the Gas Committee had now 12,000 stoves and burners of various kinds for cooking and heating purposes in the hands of gas consumers in the city and neighbourhood. In the month of July, 1885—the year before the introduction of the system of letting out stoves—the gas consumption was roughly 77 million cubic feet; whereas in July, 1888, it was 103 million cubic feet. This was at a time of the year when there was little gas used for illuminating purposes. He estimated that they had made a profit of at least £20,000 from the introduction of these gas-stoves. In answer to questions put to him after the close of his speech, he denied that the gas now supplied gave less light than that formerly in use, and said that £30,000 which the Gas Trust had saved by breaking the coalmasters' ring was devoted to reducing the price of gas, and to clearing off the debt and mortgages on the gas-works.

At the ordinary monthly meeting of the Glasgow Town Council on Thursday, complaint was made by Mr. Primrose of the insufficiency of the supply of gas in the south-western district of the area of supply; and he asked the Convener of the Gas Committee if nothing could be done to improve the pressure for that locality. There were, he said, many and widespread complaints; and he could speak from personal observation as to the necessity for improvement. Mr. Ure, Convener of the Sub-Committee on Works, said that the matter referred to had been before the Gas Committee on more than one occasion. They were quite aware that there was a difficulty in keeping up a full pressure in that particular district just now; and they had under consideration the propriety of laying down a new main there; indeed, it would have been laid before this time but for the operations, or prospective operations, of the Clyde Navigation Trustees, who were going to make a new road there; and if the Committee had moved in this matter before, they would have required to lay the main twice. They had now notice that this change would take place within the next three months; and as soon as it was possible to do so, the Committee would have the additional main laid.

Since despatching my "Notes" a week ago, I have learned that the motion brought before the Glasgow Corporation Gas Committee on the 29th ult., asking authority to pay the sum of £3000 from last year's gas surplus to the Corporation for their general purposes, was carried by seven votes against four. The matter did not come up for confirmation at last Thursday's meeting of the Town Council; so that it must be "hung up" for a month.

Business on the Glasgow Stock Exchange was reported on Monday as having been done in the shares of the Partick, Hillhead, and Maryhill Gas Company at 80s. per share. On the following day, the same price was again asked by holders; but buyers would not rise above 75s. per share, with the result that no business was done. Yesterday the same condition of things showed itself.

There is now scarcely such a brisk demand as there was for sulphate of ammonia in the Glasgow market. The spot rate is reported to be £12 15s. per ton; but £13 has been realized for January to March deliveries.

The Glasgow pig-iron warrant market has generally been dull this week. On Tuesday, however, a large amount of business was done in Scotch warrants, the price of which touched 42s. 1½d. per ton. Yesterday the market closed with the price at 41s. 9d. per ton cash.

Less activity has shown itself in the coal trade this week; but in most cases prices remain firm.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Dec. 8.

Sulphate of Ammonia.—Why, one may ask, has the market fallen so suddenly this week? and there is no answering echo to the question. It is generally understood that the letting out of large quantities of sulphate, held for a further rise, has been at the bottom of the collapse; and that the heavy make coming on behind these large prompt parcels has completely destroyed the tone of the market. In this way, £12 2s. 6d. f.o.b. Hull and Liverpool, has been touched; and there the decline remains checked meanwhile. Nitrate will not help sulphate at the present moment; for the very large November shipments (110,000 tons) are even beyond the highest estimates. The value on spot has declined to 11s. It is generally considered that the sudden drop in sulphate is uncalled for—especially as the usual margin between it and nitrate is not maintained; and it may from the present position be assumed that there will be an irregular market for the rest of the month.

LONDON, Dec. 8.

Tar Products.—The week has been marked by a little better demand for crude tar products; tar oils and pitch being in good request at improving prices. Benzole is dull; and the same feature characterizes most of the better products. The unhealthy competition for tar continues; and in some instances prices are being paid which are bound to bring a loss unless the values of products largely increase. Present prices are: Tar, according to position, 18s. to 23s. per ton. Benzole, 90 per cent., 3s. per gallon; 50 per cent., 2s. 5d. Toluol, 1s. 6d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 90 per cent., 1s. 2d. per gallon. Light oil, 3d. per gallon. Creosote, 2½d. per gallon. Pitch, 18s. to 21s. per ton. Carbolic acid (crude), 3s. 10d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 30 per cent., "A" quality, 1s. 4½d. per unit; "B" quality, 1s. 2½d.

Ammonia Products.—Sulphate has been fitful and difficult of sale; and prices at the various large outlets have varied in an unusual manner. But the week closes with the price of sulphate nearly 10s. below that of the previous week. Prices are: Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Sulphate of ammonia, £12 5s. per ton, less discount. Liquor ammonia, 2d. per lb. Carbonate of ammonia,

3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £25. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Dec. 8.]

Tar Products.—The benzol market remains without sensible change; and last week's prices may be said to be ruling to-day. There is a very fair demand for aniline oil and salt; and in time this may not be without influence on the benzol market. We hear that a few of the leading producers are about to put their heads together, in order duly to consider the situation, which in its uncertainty must be, to say the least, unsatisfactory both to the sellers and users. Of solvent naphtha, creosote, and crude carbolic acid, there is little fresh to say, except it be to note that all these products are moving off freely. Anthracene is still firm at old rates; while pitch is slowly moving upwards. It is rumoured that 22s. 6d. is being asked in London; 20s., in Liverpool; and a price intermediate between these two, f.o.b. the Humber ports.

Sulphate of Ammonia.—Sulphate of ammonia has met with a decided check; and £12 3s. 9d. has, we hear, been accepted for shipment at Hull, early delivery, though the price remains at £12 5s. at Leith and London. Nitrate values seem to have had something to do with this fall, which should go no further if makers are but circumspect, as for a few weeks, at any rate, there will be but a moderate quantity required. In some quarters the demand for liquid ammonia has increased, and sal-ammoniac has risen £2 per ton in sympathy with the increased price of acid and salt.

THE PRICE OF WATER AT ELLAND.—The Elland Local Board having obtained a reduction in the price of water supplied to them by the Halifax Corporation, it is suggested that the benefit of this reduction should be at once given to the consumers in the district. One of the local papers points out that there are two courses open to the Board in dealing with this matter—they may retain the present prices, and devote the extra profit to the relief of the rates; or they may give the consumers the benefit direct. Consumers—manufacturers especially—claim that the right thing, and that which will most conduce to the good of the town, is to at once reduce the price. By this means, it is urged, consumption will be stimulated, and manufacturers and others who use large quantities of water will have better opportunities of carrying on their industries; while new enterprises might also be encouraged in the town. Of course, what the Board have to consider is whether the water has paid for itself at the old rate. If so, then probably the concession will be granted; but if not they will be compelled to keep the water charges as they are.

THE COSTS OF REMOVING THE HUNTER TRIAL TO LONDON.—It is stated that the costs of the rule for a *certiorari*, and the extra costs incurred by the removal of the indictment in the Hunter case from Lancashire to London, have recently been sent in for taxation. The bill of costs delivered amounted to £373 16s. 10d., made up of £293 4s. 6d. payments out of pocket, and £80 12s. 4d. The total amount of the bill as taxed and allowed against the defendant Hunter is £128 3s. Thus £245 13s. 10d. of the total amount charged has been disallowed by the taxing-master; and the total amount allowed falls short of the actual payments by £165.

THE NEW WATER-WORKS OF THE ALFRETON LOCAL BOARD.—The Alfreton Water Committee's new impounding reservoir at Lindway, has now been formally inaugurated by Mr. Joshua Roberts raising the valve and letting in the water. The reservoir is substantially constructed, and of sufficient capacity with the old reservoir to store water enough for the driest summer. The capacity of the reservoir is 8 million gallons. Since the resignation of the late Engineer, Mr. W. H. Radford, C.E., of Nottingham, has superintended the works; and he has brought them to a satisfactory conclusion.

THE WATER SUPPLY OF NORTHALLERTON.—At their monthly meeting on Thursday, the Northallerton Local Board had under consideration the question of obtaining a supply of pure water for the town. The Clerk read a memorial, which had been drawn up at a special meeting of the Board and forwarded to the Ecclesiastical Commissioners, dwelling on the importance of securing a supply of potable water, and asking them to allow of its being taken from Osmotherley Moor. To this a reply had been received from Messrs. Smith and Gore, the Agents to the Commissioners, in which they stated that they were prepared to advise the Ecclesiastical Commissioners to grant to the Board, for a term of 42 years their interest as Lords of the Manor of Northallerton, in the use of certain waters situated on the unenclosed portion of Osmotherley Moor, together with the use of their rights to the surface, to erect any necessary works thereon, or sink any well or tank—the Board to pay a yearly sum of £10, and to undertake on their part to compensate for any damage that may arise to the stinholders on the common, and riparian owners on the streams below. The Clerk remarked that he had written to the Commissioners' local agent, asking him to explain the term 42 years, and requesting that the grant might be made in perpetuity. A reply had been received that he did not think the Commissioners could make the grant in perpetuity; but he would recommend that the term be extended to 63 years, and the cost £20 per year. After some discussion, the Clerk was requested to write to Messrs. Smith and Gore asking them to either grant the right in perpetuity or sell a portion of the moor; at the same time pointing out that under the arrangement at present suggested, the Board could not borrow money from the Local Government Board.

STRIKE AT THE BLACKBURN GAS-WORKS.—Owing to a dispute about wages, a number of the stokers at the No. 2 gas-works of the Blackburn Corporation have come out on strike.

SUGGESTED PURCHASE OF THE HEANOR GAS-WORKS BY THE LOCAL BOARD.—At the meeting of the Heanor Local Board last Tuesday, the Clerk was instructed to write to the Langley Mill and Heanor Gas Company, asking if they were willing to negotiate with the Board for the transfer of the gas-works.

LEAD POISONING AT DRIGHLINGTON.—Dr. Forsyth, Medical Officer of Health for Drighlington, in presenting his monthly report at the meeting of the Local Board last Wednesday, stated that he had been in attendance on several cases lately where there had been symptoms of lead-poisoning. On examination of some of the town's water-pipe joints, traces of lead had been found by him. He advised the Board to have some samples of the water analyzed by a public analyst, as he was not altogether satisfied with the quality of it as it at present passes along the mains. The Board decided to send a sample of the water to the Leeds public analyst.

ILKESTON CORPORATION WATER SUPPLY.—At the monthly meeting of the Ilkeston Town Council last Tuesday, on the motion for the adoption of the minutes of the General Works Committee, Mr. Moss proposed an amendment to the effect that an engineer be employed to advise the Council as to what course they should take in reference to a new water scheme, and that the minute recommending that two pumps should be put in the large shaft at Kirk Hallam, and the large engine shifted nearer the shaft and attached to the pumps, and a temporary engine-shed be erected, be expunged. Mr. Mitchell seconded the amendment, and urged the Council to purchase new plant if they were going to ascertain whether or not a permanent supply could be obtained from this shaft. Mr. Robinson pointed out that the sum of £7500, which the scheme was estimated to cost, was not required to test the supply at Kirk Hallam; but a great deal of it would be required in laying down new mains throughout the town. Mr. Trueman objected to the appointment of an engineer, as the Committee and Surveyor were, he thought, quite qualified to deal with the matter. He suggested that they might make £2500 do instead of £7500, and let the mains remain as they were for a time. Alderman Snodbury contended that there was an ample supply of water for the use of the town. Mr. Haslam opposed the recommendations of the Committee, in a lengthy speech. The water supply of the town, he said, was a disgrace to them, depending as it did on several different stations. Mr. Hall, whom they had called in to report on their plant, had condemned it. They ought to find a site for a plentiful supply, have one station, one set of plant, and one set of men. After further discussion, the amendment was lost by 11 votes to 7; and the minutes were adopted without alteration.

THE QUALITY OF THE LONDON GAS SUPPLY

DURING THE FOUR WEEKS ENDED DEC. 4.

CHRISTMAS HOLIDAYS.

In consequence of the Christmas Holidays, the next number of the JOURNAL will be published on Monday morning. Correspondents and Advertisers will please note this, and let us have any communications not later than the first post Saturday.

TO ADVERTISERS.

Undisplayed Advertisements—Situations Vacant or Wanted; Apparatus Wanted or for Sale; Contracts; Tenders; Public Notices, &c.—cost 3s. for the first six lines (about 42 words) or less; and 6d. for each additional line.

Post-Office Orders should be made payable at the Chief Office, St Martin's-le-Grand; Cheques crossed "Union Bank of London"; and drawn to the order of WALTER KING, 11, Bolt Court, Fleet Street, E.C.

TO CORRESPONDENTS.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a proof of good faith.

WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, DECEMBER 18, 1888.

THE GAS INSTITUTE IN EXTREMITY.

THE time has now arrived when the question of the future of The Gas Institute must be decided; and, unfortunately, those to whom the general body of members naturally look for guidance in all matters affecting their corporate existence, have not made the expected sign. The decision of the fate of the Institute will, therefore, be left to the unassisted judgment of individual members, unless the President, for whose promised declaration of policy they have waited in vain, breaks silence during the next fortnight with the

expected ultimatum. At the time when the members of Council and others (for reasons which need not be repeated) consummated the great secession which shook the Institute to its foundations, and left it with a fragmentary governing body, the President issued to the members, from the Council meeting at which the bulk of the resignations were received, a notification of the fact, and a request for abstention from similar action until a general meeting could be called. It was also stated that an extraordinary general meeting would be convened in the course of the autumn. The latter announcement made the preceding request reasonable; for while it would have appeared audacious, to say the least of it, to ask members who sympathized with the seceders to wait a whole year, and pay another subscription, before giving effect to their inclination, it was only common prudence to check a movement that might have resulted in swift disintegration of the Institute. At the next Council meeting, held on Sept. 4, and alluded to in our issue for the following week, it was decided to abandon the proposed meeting, under circumstances which looked very like a difference of opinion, or at least a misunderstanding, between the President and some of the members of the Council. We did not lay stress upon this point at the time, because we recognized that both President and Council had as much as they could expect to accomplish by the end of the year, if they worked in the most complete harmony. We pointed out, however, that by thus depriving members of the opportunity of considering the position of the Institute during the period covered by the current subscription, the President and Council took upon themselves greater responsibility for the success of next year's ordinary meeting. It having been announced that another Council meeting would be held in November, we showed that it was due to the members that, after this meeting, a statement of policy should be promulgated, in order that they might decide whether or not to renew their subscriptions. That in so arguing we only spoke the sentiment of many members was proved by the interrogation of the President at a subsequent Midland Association meeting by Mr. P. Simpson, of Rugby, who was manifestly in touch with his assembled colleagues in this action. Upon that occasion Mr. Henry Woodall—whose public-spirited policy in visiting the meetings of the various District Associations deserves the fullest recognition—stated that he had no doubt that the policy of the Council would be put forward after the November meeting. This portentous meeting was held on the 27th ult., and was adjourned for a fortnight, nothing being done, but the difficulty of the situation having been aggravated by the retirement of another member—Mr. A. Colson, of Leicester. Although we are not in the secrets of the Council, this fresh resignation, by one of the most respected of the younger and rising order of engineers, struck us as not hopeful for the future; and distrust was fanned by the rumour that one if not two other members of the Council had begun to feel their position growing intolerable. At any rate, the adjourned meeting took place last Tuesday, and that something is very wrong may be inferred from the fact that the President, prompt man of business as he is, has not up to our going to press made any statement for the information of the members, who, as he is well aware, expect a declaration from him before the end of the year.

The question that consequently arises is plainly this: Has there occurred anything like a schism in the Council; or does the absence of any declaration of policy merely mean that neither the President nor any member has a distinct policy to recommend? If the President, upon whose request members have refrained from resigning, has been baffled in any way in such steps as he may have considered necessary for redeeming his pledge, it is only what he owes to himself that he should publish a statement to that effect, and follow it up by resigning. He, at least, cannot escape personal responsibility in this matter. We do not here wish to compare Mr. Woodall in reputation and standing with the ordinary members of the Council, although the comparison is one that his friends would not fear. The plain fact is that he is the President; and it is to him that the general body of members look for guidance, in a way that they certainly do not look to any single member or group of members of the Council. He has manfully stuck to the ship through a condition of affairs unprecedented in the history of the Institute, in the hope that he would be able to bring it safely through its troubles; and if he does not break silence with a satisfactory statement directed to this object, the members whom he has induced to remain will construe his reticence as a confession of defeat, and

will solve the difficulty, so far as they are concerned, by not renewing their subscriptions next year.

There is no mistaking the elements of a satisfactory policy for The Gas Institute. It means that the organization shall be reformed in such a manner that the members who have retired can come back again with honour, and that the besetting evil which was the prime cause of their withdrawal—trade jealousy—shall be for ever eradicated. The idea that the Institute can exist for long without including in its membership the leaders of the gas engineering profession is preposterous. It comes to this, that with the various District Associations so popular and thriving, a central society of the same order has to justify its existence. It is not now as it was in the early days of the British Association of Gas Managers, when a gas manager might only meet his nearest neighbour once a year at the general meeting. For most of the practical purposes which the British Association was established to serve, the District Societies have fully supplanted it. They enable men occupied in the same part of the country, and therefore admitting a common bond in addition to that of their calling, to meet together for the friendly interchange of ideas and experiences; and they are free from some of the objectionable features of the annual gathering from all quarters. There is no carping between the members; there are no cliques; and those who find it to their interest to manufacture grievances and sow dissension, discover that the field is too small for their labours. Why should busy men take the trouble to give up a week of their time, and travel hundreds of miles, it may be, to a meeting which they find spoilt for them by the play of spite, rancours, and jealousies which are no concern of theirs; and why should they accept office in a society which exposes them to persecution actuated by the pettiest and most personal of motives? For no other crime than standing by and doing their best for The Gas Institute, a number of members have been compelled to retire from it; but these are the very men who are at the present time among the most honoured members of the comparatively cosy and comfortable District Associations. If they are not fit to be members of The Gas Institute, why are they welcomed at the district meetings? If, as a certain section of members and their hangers-on have of late tried to make out, these men have been guilty of every possible crime towards the Institute, how comes it that they are so universally respected by those other colleagues who, by neighbourhood, ought to know them best? Supposing for a moment that these leaders of the profession, and those who respect them too highly to support any society from which they are by implication excluded, keep aloof from the Institute, how can the latter justify its existence? Where can it meet when London, Glasgow, Liverpool, Birmingham, and many other places give it the cold shoulder? We take our position firmly on the point that—apart from all consideration of the personal respect due to these gentlemen—no national professional association of this kind can justify its existence unless it includes (not necessarily always in office, but at least in full membership and active sympathy) the recognized heads of the profession. If anybody will dispute this point, we should like to see what sort of arguments he proposes to use.

It is idle for men who, whatever their estimable qualities, are not recognized leaders of their colleagues, to think that an accidental position in office in a mutual society confers any additional lustre upon their personality. Men who are already eminent confer distinction upon any society to which they belong; but no society, unless it is known to be mainly composed of better men than himself, can confer distinction upon a member. These are, or should be self-evident truths; and their application to The Gas Institute at the present crisis in its existence is not less obvious. There is no need for the mention of names; but it is incontrovertible that any association which permits to remain outside it the most eminent of those for whom it is ostensibly formed, must be a society of mediocrities. What attraction, dignity, or authority can attach to an assembly of such a quality? Every society requires the support of the best men that can be encompassed in it. The members who have already achieved their positions in life will attend its meetings for the purpose of clashing wits with their peers, and with the desire to help those of their professional brethren who are yet climbing upwards. Men with their future before them will gladly come together to learn from their seniors, and to hear, perhaps to consult, the shining lights of their calling. Can an association deprived of these, its original reasons for existence, live and

thrive after it has lost them all? It may linger on through a discredited decadence, more or less protracted, in the interest of those whose usurpation of nominal leadership is rendered possible only by the absence of better men; but where is the glory of this? Wherefore we say that if The Gas Institute is to be saved, the President must immediately disclose sufficient reason for the renewal of their subscriptions by those members whose desire is for its continued existence in honour, unity, and usefulness.

A DISCUSSION AT THE MANCHESTER DISTRICT MEETING.

IN another column will be found a report of the proceedings at the recent meeting of the Manchester District Institution of Gas Engineers, when the interest principally centred in the discussion on Mr. J. Dalglish's paper on the effects of oil and other illuminants on gas consumption. Before noticing the speakers' remarks, it will be well to draw attention to the fact that, for various reasons, this debate has been deferred for a year after the reading of the paper, which cannot be regarded as a satisfactory arrangement. There is too much of the "resurrection" aspect about the review, after such a long interval, of statements which, however true and valuable, must have been far more interesting when fresh. Life is too short, as well as progressive, to allow us to keep open a "suspense account" of our views and projects for a whole twelvemonth. The incident in question may be exceptional; and it is to be hoped that it will remain so. There are many objections to postponing the public discussion of technical papers; and, so far as can be seen, only one argument in favour of this course, which is that those who take part in the debate may have time to bring up their data and form their opinions respecting the author's statements. There is not much in this plea, however, when it is examined; and we suspect that it is only advanced as a cloak for the real reasons for putting off debates, which are commonly want of time, and fatigue of the meeting by other business. This is really an argument for short papers, if discussion is looked for, and especially for having all technical communications printed in advance and distributed to the members a day or two before the date of the meeting at which they are to be read. If this latter point were attended to, there would seldom be any necessity for the suggestion to defer a discussion; which is a growing, though a bad practice. Admitting the disadvantage under which the speakers laboured, the discussion was as good as could have been expected. A useful contribution to it was a letter from Mr. Newbigging, now absent on a South African engagement, in which the writer offered some sound advice, worded in a rather picturesque style, upon the conduct of gas undertakings with a view to gaining public favour. While admitting the force of Mr. Newbigging's objections to the deposit system, however, it may be well to remark by way of comment upon the assertion that "all round the practice of enforcing the payment of "deposits is a most objectionable one," that the writer of this sentence seems to have forgotten for the moment that Gas Companies are under compulsion to supply all comers, whatever their commercial reputation. There are certain customers whom the most enterprising and trustful of shopkeepers may reasonably refuse to serve with goods unless the money in payment is first passed over the counter, and safely deposited in the till. If the condemnation of the deposit system is modified to allow of exception in such cases, we willingly subscribe to it; for, as unintelligently applied by some Gas Companies, it has undoubtedly done more damage than can well be estimated. Mr. W. Woodward, of Bury, said a trenchant thing when—having premised that the selling price of gas had been brought down—he declared that "they had neither deposit system nor meter-hire at Bury; and this year they had an "increase of more than 10 per cent. in the consumption, "whereas in other years they had had a decrease." We cannot go with Mr. T. Banbury Ball, who seemed to think that the question of the desirability of a consumer depends entirely upon the amount of his account. It is easy to argue that the transaction of a very small amount of any kind of business does not pay; but what would become of trade if every shopkeeper, merchant, railway company, and fire or life insurance agent conducted his affairs upon this principle? It is curious that very soon after Mr. Ball talked in this vein in Manchester, a proposal to reduce the price of gas in his own town of Rochdale was opposed by an Alderman on the ground, among others, that hundreds of consumers were already supplied at a loss. It is a mischievous thing to go through a classification of the gas

consumers of a town according to whether they require two-light, five-light, or fifty-light meters, and to discriminate which pays best. All help one another; and this axiom cannot be lost sight of without danger of going further wrong among the fallacies of "fair" price, commercial value, and the other delusions that have everywhere served to cheat consumers of their dues. To sell gas to everybody at the lowest possible price consistent with the safety of the capital invested and the quality of the commodity, is the only safe policy for owners of gas undertakings, whether public corporations or statutory companies. The President, Mr. Duxbury, of Darwen, offered good evidence of the advantage of cultivating the cottage class of consumers; and Mr. Dalgliesh satisfactorily wound up the debate. On the whole, while the discussion was not perhaps all that might have been desired, it shed a certain amount of fresh light upon a question that requires elucidation in accordance with local conditions in all parts of the kingdom.

GAS AFFAIRS IN DUBLIN.

THERE is another squabble between the Corporation of Dublin and the Alliance and Dublin Consumers' Gas Company; the subject this time being the illuminating power of the gas supplied within the city. One of these Dublin gas disputes follows another, at short intervals, without the introduction of any such difference as might prevent the repetition by Aldermen and Councillors of their stock denunciations of the Company and all its works, at the same time that the subject-matter is always varied sufficiently to give a superficial aspect of freshness to the quarrel. The last "row"—it is impossible to use dignified language to describe these particularly undignified outbreaks—is a result of the recent appointment of a Gas Inspector who, there is reason to believe, was specially selected for the post because he was deemed likely to make things generally disagreeable for the Company. The fact of the Inspector being very nearly related to the Secretary and General Manager of the Company gives a peculiar zest to the disputes of which he is expected to be the cause. He has reported to his employers that the gas was below the standard on seven recent occasions; and his bare statement, communicated to the Town Council by an Alderman, was, of course, quite sufficient to call down condemnation on the Company, without a suggestion of their being heard in their own defence. This is apparently the idea of fair play entertained by the majority of the Corporation; for we do not see that one voice was raised at the Town Council meeting to point out the *ex parte* nature of the evidence on which the Company was being held up to public opprobrium. As soon as the proceedings were reported to the Gas Company, however, the Directors and their General Manager prepared for action. Seizing upon the fact that dates were given for the alleged periods of shortcoming on their parts, they have challenged the Corporation to prosecute them for the damages which, according to this story, they must have incurred under the Act. As Mr. W. F. Cotton points out, in the communication to the Corporation of which we publish an account elsewhere, if proceedings are not taken to recover these penalties, it will look as though the Gas Committee are willing to slander the Company, yet are afraid to put their accusations to the proof. As the matter has been referred to the Paving and Lighting Committee, it is possible that a prosecution may be impending; but, on the other hand, it is equally likely that, the aspersions having been made, nothing further will be heard of the matter.

THE TRIAL OF MR. CARR.—The trial of Mr. William Carr, at the Leeds Assizes, on the charge of unlawfully mutilating "a certain book" belonging to the Halifax Corporation, has been specially fixed to take place to-day (Tuesday) before Mr. Baron Pollock.

MID-SUSSEX WATER COMPANY.—We understand that an allotment of shares in this Company (the prospectus of which was published in the JOURNAL for the 27th ult.) was made on the 5th inst.; but, the whole of the shares not having been applied for, the Directors have decided to allow the list to remain open for a short time, to enable those who are desirous of becoming shareholders to send in their application.

MR. PERCY G. WINSTANLEY (son of Mr. George Winstanley, Engineer and Manager of the Newcastle-under-Lyme Corporation Gas Works) has been appointed Secretary and Manager of the Halesowen Gas Company. In moving the adoption of the Gas Committee's minutes at last Tuesday's meeting of the Newcastle Town Council, Mr. Briggs referred to the appointment obtained by Mr. Winstanley, jun., who, he said, had been an efficient servant of the Corporation for six years. He had now gone to take a responsible position elsewhere; and he was sure the Council wished him success.

Water and Sanitary Affairs.

IN Lord Bramwell, the Water Companies (in common with the proprietors of other public undertakings of a similar class) have always found a vigorous and consistent champion. To those who favour the so-called public policy of compulsory purchase by municipal bodies, we commend some remarks which will be found in his Lordship's address on "Economics r, Socialism"—recently re-issued by the Liberty and Property Defence League. You do not, says Lord Bramwell, compensate a man when you take from him what as a matter of business he would rather keep—even if you pay him twenty shillings for his sovereign. Almost immediately after this, his Lordship makes a pointed reference to the case of the London Water Companies, in connection with the question of annual value. The Companies were originally authorized to charge according to the real annual value of the houses supplied with water. But what happened? Only a few years ago, at the instance of a private member, it was enacted that the charge throughout the Metropolis should be on the rateable value, "which is" "very commonly five-sixths of the real value. The measure was passed, adds the writer, "by some who knew no better, by "others who did, not without a blush; but it was £9000 a "year loss to one Company."

These schemes and ideas receive encouragement from Parliament; while the far more urgent question of maintaining the purity of the Thames, and placing adequate powers at the disposal of the now helpless Conservancy Board, is allowed to remain in abeyance. Is it more important that a man should pay a few shillings less for the water annually supplied to him, than that the quantity received, whatever it may be, should be pure and undefiled when it is sent into his house? The question answers itself in days when people scoff at the primitive customs of their forefathers, and plume themselves on their zeal for sanitation. It is not our habit, nor wish, to be alarmists; but, nevertheless, it may be well to remember what river pollution has effected in bygone times. The events which led to the Health of Towns Commission more than forty years ago ought not to be forgotten. It was then tardily realized that the sewage of London which had formerly been accumulated in cesspools had been gradually transferred to the Thames; and, to quote Sir Francis Bolton's description of the consequence, the river itself became a polluted sewer on an enormous scale, with a mass of water, black and foul, passing continually up and down at each change of the tide—"a condition of things "which culminated in the cholera outbreaks of 1845 and "1849." Of course, the shocking state of affairs which then existed can never be repeated, because it is now illegal for the Metropolitan Companies to take water for domestic consumption from any part of the Thames below Teddington Lock. The present, or the threatened, danger is to be traced to the riverside towns situated above the present intakes of certain of the Companies; and the point is whether the Local Authorities who bear rule in those localities are to be permitted to turn certain stretches of the Thames into public sewers. All will be agreed that it is not expedient; but, unhappily, the law seems to favour the offenders—if not individually, at least collectively.

With regard to the rights of individuals *inter se*, the case of *Ballard v. Tomlinson*, decided in the year 1885, is no doubt an important authority; but the decision of the Court of Appeal (reversing that of Mr. Justice Pearson) was of a more or less qualified character. It was then laid down that no one has a right to use his premises in such a way as to be a nuisance to his neighbour; and, therefore, if a man puts filth or poisonous matter on his land, he must take care that it does not escape so as to poison water which his neighbour has a right to use, even though the neighbour may have no property in such water at the time it is fouled. The argument, put in another way, involved the question whether anyone of those who have unlimited rights of appropriation has also a right to contaminate that common reservoir or source described as percolating water, or whether he is bound to do anything which will prevent those who enjoy a similar right of appropriation from receiving the water unaltered in quality. This latter question Mr. Justice Pearson decided in the negative; but, as just mentioned, the Court of Appeal took a different view. The result is that, although nobody has any property in such a source of water supply, yet everyone has a right to appropriate it, and to appropriate

it in its natural state. Therefore, it becomes illegal for one man to foul the common source, so as to prevent his neighbour from enjoying the full value of his right of appropriation. This is sound doctrine. If similar principles could be enforced as between the Staines Local Board, on the one hand, and the Conservators (as representing the rights of the public and of the London Water Companies) on the other, a way might be found out of the present discreditable and dangerous deadlock.

In our present issue we have to record the half-yearly meetings of three of the London Water Companies—the Southwark and Vauxhall, the Grand Junction, and the Chelsea. The rate of dividend with the first is 6 per cent.; and with the two others, 9 per cent. In each instance the Directors rendered their account with a light heart; although a wet summer had so affected the demand for water as to diminish the revenue accruing from the meter supply. The Chairman of the Grand Junction Company referred in terms of satisfaction to the new reservoir at Ealing; though slightly apprehensive lest some rigid economist should object to the expense of the opening ceremony. It is perfectly certain that neither the Local Authorities nor the public have an adequate idea of the magnitude of the operations necessary to supply the Metropolis with water, and the Companies will act wisely in seizing every opportunity to dissipate the prevailing ignorance on this subject. The Chelsea Company's balance-sheet afforded the usual example of economy in expenditure; leaving a trading profit of 70 per cent. In this respect the undertaking stands unrivalled, except by that of the Kent Company. A remarkable feature in the Chelsea Company's district consists in the enormous demolition of old houses; something like 1000 having been lately pulled down. This process, which might have been expected to reduce the income of the Company, has been greatly neutralized by the rapidity of building operations, and the higher value of the new structures compared with the old. The activity of the builders between Acton and Sunbury has also served to benefit the Grand Junction Company; though necessitating additional works to meet the demand. The vote of thanks to the Chelsea Directors gave rise to an amusing example of gratitude for favours to come; the mover of the resolution dwelling on the steady progress that was being made "towards the maximum dividend of 10 per cent." One discouragement bearing on the London Companies in their efforts to economize expenditure, consists in the perpetual and extraordinary growth of local imposts, in the shape of rates and taxes. This was mentioned by the Grand Junction Chairman, and still more emphatically by the Chairman of the Southwark and Vauxhall Company, Sir H. E. Knight, describing the increase of this burden as "continual and enormous." The rates and taxes of the Company have risen by £800 in the last half year, as compared with the corresponding period of 1887. More than 8 per cent. of the gross income of the London Water Companies is thus absorbed—independently of the income tax. We have before remarked that the Local Authorities will feel the difference, if ever they obtain possession of the London Water-Works. We observe that no reference was made at any of the meetings to the approaching establishment of the County Council for London. An item of scientific interest relates to the Streat-ham well of the Southwark Company. This somewhat famous undertaking has, like others, resulted in reaching the primary rocks, and demonstrating the absence of the lower greensand in the vicinity of the Metropolis. Sir H. E. Knight signifies that the idea of an unlimited supply of water from the strata under London is now at an end; and it thus becomes a matter of increasing importance to protect the Thames from pollution. Concerning the absence of the lower greensand, it should perhaps be borne in mind that, although the statement is practically correct, it is not literally true; a thin stratum having been found under the Tottenham Court Road.

THE *Garth Castle*, in which Mr. T. Newbigging left England for South Africa to fulfil an engagement at Johannesburg (as intimated in the JOURNAL for the 27th ult.), arrived safely in Cape Town last Friday, and "all well" is reported.

THE duties of Mr. J. F. Bromley, late of the Bolton Corporation Gas Department and now Manager of the Batley Gas-Works, have been divided by the Gas Committee; and Mr. Walter Collins, the late Borough Analyst's son, has been appointed Gas Examiner.

WE understand that Madame Altling-Mees commenced yesterday a series of lectures on cooking by gas in the new hall of the Gaziers Belges, Boulevard du Nord, Brussels. From thence, about new year, Madame Altling-Mees purposes proceeding to Lille to fulfil a similar engagement.

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(FOR STOCK AND SHARE LIST, see p. 1083.)

THE week just concluded has not been a bright one for the Stock Exchange markets. It opened as gloomily as possible; and, indeed, Monday was perhaps the flattest day all-round that we have seen for a long time. Subsequently there was some degree of improvement, as probabilities pointed to a relaxation of the stringency in the Money Market; but towards the end there was another fall back, and closing prices were below the best of the week. It may be expected that the markets will continue in this unsatisfactory condition until the monetary prospect becomes clearer. As the present position of affairs prejudicially affects even the highest class of securities, it might have been expected that the Gas department would exhibit a greater falling off than it does; the actual extent being very slight indeed. Gaslight "A" has receded 1 in quotation; but the prices at which business has been done are much about the same as those of the previous week. The stock has been extremely quiet; and on the last three days of the week, there was not a single transaction recorded in it. In fact, there was almost as much business done in the Company's secured stocks as in the ordinary. All the debenture stocks are quoted *ex div.* since Thursday at old *cum div.* prices. If this is right, it is equivalent to a rise of from 2 to 3 per cent. in each. There was a fair amount of business done in South Metropolitan; but the prices were not very good, though the closing mark on Saturday for the "A" stock was the best of the week. The £50,000 of Five per Cent. Debenture Stock which was disposed of at the Mart on Friday averaged about £130 8s. per £100 of stock; yielding, therefore, nearly £3 17s. per cent. per annum as an investment, which may be considered a handsome return for so excellent a security. Nothing at all has been marked in Commercial; but we fancy it is being quietly bought by those who know what they are about. Suburban and Provincial undertakings have been almost unnoticed, and present no feature. The Foreign division has had rather a weaker tendency. Imperial Continental has receded 1; and Bombay old is $\frac{1}{4}$ lower. The Water Companies have been so excessively inactive that only two or three transactions have been marked in them all the week. Changes are few and unimportant; comprising a fall of 1 in East London, and a recovery of 1 in each of the Southwark and Vauxhall issues, upon adjustment of *ex div.* quotations.

The daily operations were: On Monday, Gas was at its most active point, and prices were steady, though only moderate. Tuesday's Gas business was decidedly limited; and prices were much the same as the day before—if anything, a little better, though Gaslight "A" was quoted 1 lower. In Water, Southwark and Vauxhall was the only Company touched, and the ordinary shares rose 1. On Wednesday, Gas was quiet again, and prices generally were not good, especially for Bombay and Imperial Continental. In Water, East London was weaker, and fell 1. There was a shade more activity in Gas on Thursday—mostly in Gaslight and Coke and South Metropolitan issues. The only change was a fall of 1 in Imperial Continental, and $\frac{1}{2}$ in Bombay. There was nothing at all done in Water. On Friday, Gas was quiet, and prices were low; but quotations remained unchanged. On Saturday, a couple of transactions in South Metropolitan were all that was done in Gas; and all quotations closed without further variation.

ELECTRIC LIGHTING MEMORANDA.

THE ELECTRIC LIGHTING OF KENSINGTON; AN OLD DELUSION—ELECTRICIANS' ENTERPRISE—ELECTRIC LIGHTING OF THE PARIS THEATRES AND CONCERT ROOMS.

IT has been mentioned repeatedly in this column that various electric lighting schemes are afoot with special reference to that most favoured of London districts which centres in Kensington. There is already a central station supplying a small number of houses in West Kensington; but this is nothing to the business that half-a-dozen separate electric lighting interests expect to do when once fairly started in the neighbourhood. The House-to-House Company, which works under the supervision of the hitherto unfortunate Mr. Robert Hammond, seems to have greatly impressed the Special Committee of the Kensington Vestry who were appointed some time since to inquire into the various electric lighting projects affecting the parish. A deputation of the Committee went to Eastbourne to inspect the lighting of this pleasant town, which is Mr. Hammond's mainstay; but it is stated that they could not find time to go to Deptford, to see the new station of the Metropolitan Company. The result of this blunder on the part of the Committee has been the return of their report by the Vestry, together with the nomination of half-a-dozen more members "to strengthen the Committee and equalize the representation," as the report has it. The Vestry, for their part, are not much wiser than their Committee, who fell too easily under Mr. Hammond's fascinations; for they appear inclined to lay down the principle that the interest of the consumer requires the active competition for business of two electrical undertakers in every district. They are not yet prepared to concede the advisability of unlimited competition, and the consequent interminable trouble with superfluous wires; but they cling with touching simplicity to the belief that two favoured undertakers will always vie with each other in the attempt to give the

better service at the less cost. It is a pity to dash such infantile hopes; but the electricians will not overlook the teachings of gas supply, if the Kensington Vestrymen ignore them. There are the examples of Brighton and Edinburgh to show the inevitable consequence of attempting to pit one Gas Company against another in the same district; and there is no reason to suppose that men of business will look less keenly after their own interests when these are bound up with electricity than did their precursors in the days of competitive gas undertakings. If the Kensington Vestrymen want to make different electric lighting companies rival each other without detriment to themselves at the time and to the public afterwards, let them be given adjacent and similar, but independent districts. In this way, they will begin with all the advantages of that districting system which the London Gas Companies did not achieve until enormous amounts of the capital, which the consumer of the present day has to pay interest for, had been lost through insensate competition.

As an indication of the difficulty experienced by electric lighting contractors in obtaining orders for street lighting, and also of the lengths to which some of them are prepared to go by way of advertisement, it is reported that Messrs. Laing, Wharton, and Down have agreed to fix and run six arc lamps for a month, free of charge, in the streets of Reading. The offer has been accepted by the Town Council, who are to provide the necessary lamp-posts and supports for wires, as they are naturally willing that the local public should see the effect of electric lighting on such easy terms for the town. Whether Messrs. Laing and Co's experiment will lead to business is, of course, uncertain; but the experience of other towns with the arc light is not encouraging. It seems impossible that advertisement upon such a lavish scale can pay the contractors; but this is their affair. The incident should be instructive for gas companies, and teach them to be a little freer upon occasion with displays of the capabilities of gas. To people who have never seen anything better than the ordinary street gas lamp, the possibilities of gas for lighting streets and open spaces are as unsuspected as are the qualities of electric lamps to those who have had no experience of them.

The progress of electric lighting in connection with theatres and concert halls in Paris has been recorded with particular fulness in the French technical journals. It appears that the managements of these places of amusement have largely adopted the system of engaging with certain contractors for the supply of the lighting required in consideration of an agreed payment. In this way the contractor is responsible for everything connected with the lighting service, down to the minutest detail; the management having nothing to do with it. This is a very different state of things to that which prevails when similar establishments are lighted with gas, when the management merely pays a rental to the gas company, and has to undertake all the interior service beyond the meters. Up to the present time, however, the new system has worked fairly well. The Continental Edison Company light nine theatres, including the Opéra and the Comédie-Française, and used to light one more; but the contract for this has just expired. A private contractor lights five other theatres; the Electric Lighting Company light three more; another similar Company light the Scala concert; and the Hippodrome has its own installation. The lighting of the Opéra is far and away the most important contract of the kind; requiring nine steam-engines and fourteen dynamos established in the vaults. The complete lighting service includes 6500 incandescent lamps, ten Jablochkoff lamps on the façade, six more in the engine-rooms, and eight Pieper regulators in the loggia. There is nothing remarkable in the lighting arrangements of the other theatres. No comparative statement of the cost of the new and old systems of lighting has yet been published; and, of course, it is not known how much the Paris Gas Company have lost by this irruption of electricity into their old domain, the inciting cause of which is doubtless to be found in the catastrophe at the Opéra-Comique.

THE STOCKTON AND MIDDLESBROUGH WATER BOARD AND THEIR GENERAL MANAGER.—The General Manager of the Stockton and Middlesbrough Water Board (Mr. D. D. Wilson) has recently applied for an advance of salary; and the following flattering resolution has been passed by the Finance Committee of the Board:—"That a gratuity of £100 be granted to the General Manager in recognition of his services in connection with the recent parliamentary contest; and that his salary be advanced to £850 per annum, to date from the termination of his seventh year—the engagement to be for three years."

DEATH OF MR. W. MATTHEWMAN, OF LEEDS.—The death is announced, as having taken place quite suddenly last Thursday, of Mr. W. Matthewman, who for many years had been in the service of the Leeds Corporation as Secretary or Chief Clerk in the Water-Works Department. Mr. Matthewman, who was always regarded as a valued and trustworthy official, had been in the employ of the Corporation from the acquisition of the water-works by the town; and before that time he was engaged by the Water Company. He was about 70 years of age. At a meeting of the Water-Works Committee last Friday, the sad death of Mr. Matthewman was referred to; and a vote of condolence with his family was unanimously adopted. The Chairman (Mr. Alderman Woodhouse) and several members of the Committee spoke in appreciative terms of the manner in which Mr. Matthewman had performed his duties during all the years he had been in the service of the Corporation.

DOMESTIC FIRES; THEIR ACCESSORIES AND SUBSTITUTES.

THE domestic hearth is a standing grievance to persons of an inventive turn. The reflection that the most opulent stock-jobber, or other high product of nineteenth century civilization, who is able by the instrumentality of the railway to live thirty, forty, or sixty miles from the scene of his daily labours, and whose business methods depend upon the constant use of such essentially modern appliances as the telegraph and telephone, yet returns every evening to the comfort of such a "sea coal fire" as warmed his grandfather, is by a numerous class of restless people regarded as a reproach to the practical science of the age. All sorts of invidious things are said of the cheerful open fire in which the average Briton delights, as did his forefathers. It is condemned by economists as wasteful, by social reformers as troublesome, and by sanitarians as the aggravator of fogs; yet it retains its place in despite of all that can be said against it. The candid partizan of the general use of coal gas is forced to confess that, while for cooking a good gas-stove is as cheap as and better than most coal kitcheners, gas "fires" and heating-stoves in general, although extremely useful in their way, cannot satisfactorily supplant the old-established open fire. The late Sir W. Siemens claimed to have solved the problem of the smokeless, hot, and cheerful open fire by his combination of coke and gas; but the arrangement has not taken root in the affections of the great body of householders. There can be no doubt in the mind of anyone who has thought in earnest about the matter, that the British open hearth is one of the symbols of a stage of social organization which may not persist for longer than the period covered by one or two more generations in this country, and is already dying in the United States and the British Australasian Colonies. The permanence of the open fire for the living room, in short, with the very considerable amount of work which it entails, must depend upon the continuance of the old-world system of domestic service. Very many and serious modifications of the ordinary arrangements of people brought up in the old-fashioned European manner, in communities where there exists a class of menials, must be accepted as the price of that so-called amelioration of the common lot in which this class disappears. We in England are beginning to feel the influence of this change, in the attempts that are made to rescue much of the necessary service of a household from the category of menial offices, and even in the disrepute into which this latter phrase itself has fallen of late years. We have boldly accepted the idea that no necessary and useful service can be degrading; but it is beyond the power of argument to make some of them anything other than unpleasant. Little by little, however, the unpleasantness has to be faced until it no longer remains noticeable. In this way, nursing the sick and cooking—more especially the former—have been rescued from the list of things which no lady could be expected to know anything about. Yet if such a desirable consummation as a respectable sisterhood of cooks, to match the admirable nursing sisterhoods, should be realized, there would yet remain a good deal of tedious and disagreeable work in a household conducted on the ordinary model. We might live in flats, with porters and boot-boys to perform such services as they could undertake, but there would still remain the problem of cleaning the grates. There is no scope for enthusiasm in the work of the housemaid. The nurse may display all the qualities that ennoble humanity, the cook may exercise brains and taste of no mean order; but the work of attending to the grates is simple drudgery, and can never be classed higher than that "hewing of wood and drawing of water" which has from time immemorial been held the lowest of human employments.

When domestic servants are no longer obtainable, the glory of the British hearth will also have departed. In the Northern States of America the disappearance of housemaids is rendered less noticeable in connection with this particular matter because of the exigencies of the climate, which has long prescribed the general use of stoves in preference to open grates. Consequently the step is not so great from the use of a more or less ornamental stove placed in the room which it is intended to heat, to a furnace fixed in a cellar where it can be attended to by someone who is not strictly a domestic, and whence heated air can be drawn as required for any or all the rooms of a house. American rhymesters have made merry over the detriment to the poetry of the home affections due to the substitution of a "hole in the floor" for the hearth which formerly served as the focus of family life; but, in despite of poetry, the change has been made merely because of its convenience. The extended employment of heating by steam, distributed from central stations, is only another testimony to the need felt by modern Americans for simplifying their domestic service. It is only what one might expect, when servants are few and bad, that householders should prefer an arrangement that only involves the turning of a valve by themselves to one that requires a considerable amount of dirty work. The facility afforded by electricity for transmitting movements for the regulation of valves and dampers has not been lost sight of. Recently an American technical journal described and illustrated an "automatic electric regulator," introduced by a manufacturing concern rejoicing in the name of "The Consolidated Temperature Controlling Company," of Minneapolis. The illustration showed a furnished sitting-room on the first-floor, and a huge iron stove in the basement, with hot-air flues opening through gratings near where the fireplace of the upper room had been. The temperature controller consisted of a thermostat fixed against the wall of the room, communicating electrically, in a manner that need not be described in detail, with

an electro-motor connected with the dampers of the furnace. It is set at the temperature required to be maintained in the room by day or night, and is warranted to do its work, making "the ordinary hot-air furnace" a satisfactory heating apparatus, so long as the requirements of feeding the fire with coal, and removing the ashes, are attended to. Of course, if stove heat is to be employed for warming dwelling houses, it is as well to use a regulator for keeping the temperature uniform.

The most peculiar attempt on the part of electricians to make themselves useful in connection with house heating is, however, that narrated by Mr. Legh S. Powell, who has contributed an article to the *Electrical Review* upon the employment of electricity for lighting domestic fires. Electrical heating arrangements, although often suggested, having been found infinitely less serviceable and more costly than gas-stoves, the idea now is to use the precious current in substitution not only of the gas fire-lighting torch—which was never a satisfactory toy—but also to replace the humble "firelighter" of the oil-shops. This is a modification of the "electric furnace" which would certainly have called up a gentle expansive smile upon the countenance of Sir William Siemens. The method of procedure is simple enough. "As cinders and coke are conductors of electricity, all that is requisite to produce incineration of the fire by electric means is to make the bars one pole of the arrangement and a plate of iron, inlaid into the back fire-clay part of the grate, the other electrode. On laying cinders or coke of suitable size between these terminals and then switching on the current, the heat developed in the circuit occurs exactly where it is required—viz., at the points of contact between the pieces of fuel." It will be noticed that the electrician does not describe his purpose by the usual phrase "lighting a fire"—he "incinerates" it, which, of course, is a much more scientific proceeding! As with some other proposed and practised dealings with strong electrical currents, however, the beautiful simplicity of the method is attended with a variety of difficulties and drawbacks when it is tried in common use. It is just possible, for example, that the arcs formed between the fire-bars and the fuel might be so intense as to destroy the former in an inconsiderately brief period. Or, again, the current might not always be strong enough to ignite the fuel, and yet might waste a good deal of energy in the attempt. It appears that the author has actually made experiments in this direction in the laboratory of Mr. J. W. Swan; and although the game does not appear to have been found worth the candle, the experiments are described with some enthusiasm as pretty and moderately successful. With a current of 50 volts, Mr. Powell says he managed several times to "incinerate" about 3 or 4 lbs. of coke in small pieces, in a "small rectangular stove." The fuel had to be closely watched for 10 or 12 minutes, however, and kept constantly packed close together by the humble aid of a poker, or it would not light at all. The cost of this method of fire lighting, with electricity charged at 7d. per unit, would be from 1½d. to 2d.—which Mr. Powell admits to be a prohibitive price. The money would, of course, go much further in firewood or lighters of the common type. Mr. Swan, who seems to have been interested in the experiment, suggested that "perhaps some arrangement of a fire-clay tube to be filled with powdered plumbago and rendered incandescent by passing a current through it" might be more successful. It is a curious idea, at any rate.

On the whole, however, unless electricians can devise a means of clearing out ashes, polishing the bars, sweeping up the hearth, and laying the fire as well as lighting it, by merely pressing a button, they are not likely to gain much by meddling with the domestic fireplace. Notwithstanding its obvious drawbacks—which, by the way, chiefly affect other people—the average British householder will cling to his dusty, smoky fire as long as he can get anybody to attend to it for him, and can buy the coal to burn in it. Whenever these prime requisites can no longer be obtained, and not till then, the Englishman's open fire will give place to something else; but we take leave to doubt whether the community will be appreciably happier or healthier for the change. Nobody can tell at present what the substitute for coal fires is likely to be; it may be gas, it can scarcely be electricity.

SOME NEW BOOKS, PAMPHLETS, AND CATALOGUES.

THERE has of late been such a demand upon the columns of the *Journal* devoted to technical matters, that many things well deserving of attention have been kept over week after week. Among the rest are several books and pamphlets touching more or less upon the gas industry, some of which have awaited notice so long that their authors and publishers may be pardoned for fearing that they have been forgotten. We take the present opportunity, therefore, of dealing with some of these arrears, premising that the publications we mention together have no sort of connection with each other, except that of lying in one pile on our desk.

The first that comes to hand is a work entitled "Golden South Africa," written by Mr. Edward P. Mathers, F.R.G.S., and which is published by Messrs. W. B. Whittingham & Co., of London, and Messrs. P. Davis & Sons, of Durban and Maritzburg. This work has also been published in another edition under its second title of "The Gold-Fields Revisited." The book has probably been forwarded to us on account of the recent development of interest in regard to the supply of gas to South African towns. It appears to contain a great deal of information respecting "up-country" affairs, from which intending investors in local gas and water companies' stocks can form their own opinions as to

the prospects of such ventures. Writing of Johannesburg, for example, the reader is informed that "nothing has yet been done by the Government to light the town. At night Johannesburg streets are in darkness, but for the brilliant and welcome lights of the canteens," from which it may be inferred that the writer at least experienced a want in this regard. If the gold-field towns and others in this part of the world are not speedily provided with gas, it will not be for the want of inquiry by competent authorities. Meanwhile anybody desirous of learning something about this remarkable region will not be wrong in obtaining a copy of Mr. Mathers's well-written little book.

"The *Mechanical World Pocket Diary and Year Book*" for 1889 is a specimen of a very numerous and varied order of productions which come under notice about this time of the year. It has the good point, to begin with, of containing very few advertisements; and those that it includes would not be missed if they were omitted. The technical portion of the little book is good, so far as it goes, although the besetting evil of all books of the class—that of containing elaborate notes on elementary points that nobody is likely to forget, to the exclusion of data that are apt to escape the memory—is not absent from it. The usual equivalents of the Birmingham wire gauge are given; but the Standard wire gauge is not so much as mentioned. On the whole, however, the book is well worth the sixpence asked for it.

"Pumps: Their History and Construction," by Philip R. Björling, published by Messrs. Emmett and Co., of Manchester and London, is the substance of two lectures delivered at the Gloucester School of Art in January last. The author places pumping machinery in the fore-front of mechanical engineering, on the ground that the minerals by command of which civilized men are distinguished from savages could not be won but for pumping. It is rather idle to talk in this strain; but it is true enough that, as the pumping of water was one of the first concerns of engineers in the early days of power machinery, it constitutes a capital subject for the training of engineering students of the present age. If a student knows all about pumps, he has not much more to learn in the way of mechanical engineering.

We have received a catalogue of the Albion Engine Company, of London, Liverpool, Paris, and New York, from the sole licensees, Messrs. Hartley, Arnoux, and Fanning, of Stoke-on-Trent. The "Albion" silent gas-engines found brief mention in our account of the recent Ironmongers' Exhibition; but the later information received respecting them supports the opinion that these motors constitute a valuable additional resource to the consumer of gas for the development of power. These engines are at present listed up to 16-horse power; and with regard to their performance, it is reported that, with a poor quality of gas, a 3-horse power (nominal) engine, running at a mean speed of 183·6 revolutions per minute, developed 5·96 indicated horse power; the brake load = 4·843-horse power (weight of brake strap and apparatus additional, not included). The consumption of gas was after the rate of 31·2 cubic feet per brake horse power per hour—per indicated horse power 25·33 cubic feet per hour, firing lights included in both cases. The same size and make of engine, but with better gas, is stated to be doing a fraction more on the brake, and using 10 per cent. less gas. In both cases it is remarked that there was no attempt to obtain anything beyond a rough test of what could be done in everyday work. These "Albion" engines are made both horizontal and vertical. They are reversible, and can be had fitted with a self-starting attachment. It is claimed that as the charge is ignited at the centre, and burns both ways, there is complete combustion and absence of carbon deposit. The details of the engine are simple, strong, accessible, and not likely to get out of order.

Mr. B. Gibbons, Jun., of the Dibdale Fire-Clay Works, Dudley, has issued a striking trade catalogue, in the shape of a strongly-bound book fitted for hanging against a wall, with a shifting calendar in a pocket on the front of the cover. This is Mr. Gibbons's third illustrated list; the last, which it supersedes, dating from 1882. It contains a mass of information calculated to be of use in gas-works, drawing offices, and elsewhere. There is an interesting account of the methods of manufacturing fire-clay retorts by hand and machinery, and other data concerning the equipment of gas-works with fire-clay goods, which engineers and managers will do well to take note of. No one turning over the pages of this part of the book, however carelessly, could avoid the reflection that there cannot be any real necessity for the great variety of sections and patters of retorts catalogued or referred to by Mr. Gibbons. We note that the author draws special attention to the fact that fire-clay retorts made abroad are usually only 2½ or 2⅓ inches thick; whereas English retorts are 3 inches thick. He remarks that the thinner retorts last just as long as the thicker, and evidently inclines to recommend English engineers to give them a trial. Original articles upon points arising out of the carbonizing of coal in clay retorts complete this very well got-up catalogue, which is thus made like a text-book on the subject of fire-clay construction for gas-works purposes. It is neatly illustrated, printed, and bound.

THE THIRD DRAWING OF THE SYDNEY GASHOLDER.—This is given with to-day's number of the *Journal*, and is closely connected with drawings Nos. 4 and 5, which will be published in our next and following issues. It is, therefore, proposed to defer until the first number in January any description of the details appearing this week.

Technical Record.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

The Seventy-sixth Quarterly Meeting of this Institution was held on Saturday, the 1st inst., at the Victoria Hotel, Manchester. The PRESIDENT (Mr. T. Duxbury, of Darwen) occupied the chair. After the transaction of the formal business already recorded in the JOURNAL (*ante*, p. 980), the members proceeded to discuss the paper read by Mr. J. Dalgliesh, of Glossop, at a previous meeting, entitled

OIL AND OTHER ILLUMINANTS AND THEIR EFFECT ON GAS CONSUMPTION.

The PRESIDENT said he had to apologise on behalf of the Committee for the delay which had occurred in taking the discussion on this paper. It was read at their meeting on Dec. 3 last year; and twelve months was a long time for a discussion to be deferred. He had experienced the same difficulty in connection with the last paper he read. The result of such delay was that the subject got out of one's mind; and they had to read up for one meeting after another, or else they forgot what had taken place in reference to the particular matter to be debated. This militated against discussion, which was to be deplored, because an Institution like theirs was more valuable for the discussions which took place than for the reading of papers. However, there had been many difficulties in the way; and the discussion had been postponed from time to time. But he hoped that now it was to take place, there would be as good a discussion as the subject warranted, and as was consistent with the delay that had occurred.

Mr. DALGLIESH expressed regret at the delay. There had, he said, been other business which had necessitated the postponement of the discussion; and he was unable to attend the last meeting, held at Doncaster, so that the matter had to be again deferred. In compiling the paper, he experienced considerable difficulty in not being able to get from the various engineers and managers to whom he applied exact answers to his question as to the local consumption of oil. Very few were able to state, even if they applied to the railway companies, the quantity of oil imported into their town, nor could they give the actual number of consumers of oil, without a house-to-house canvass, which would have been very difficult, and required much time. He could not expect that managers of gas-works would go to the trouble and expense of obtaining such information; and even if they did, the time at his disposal before he had to read the paper was so limited that it would not have sufficed for such an inquiry. He therefore took this course: Taking the population of the towns as shown in the table, he allowed the Government standard of five persons to each house; and thus arrived approximately at the number of dwellings. Of course, from the returns published each year, he was able to get the exact number of consumers of gas; and deducting this actual number from the assumed number of dwellings, he arrived at the number of residents not using gas, and these, he presumed, were users of oil or other illuminants.

The HONORARY SECRETARY (Mr. Harrison Veevers, of Dukinfield) said he had received a letter from Mr. T. Newbigger, who was on his way to South Africa, in which he said that he had intended contributing something to the discussion on Mr. Dalgliesh's paper, and had jotted down a few things that had occurred to him. The enclosure was as follows:—"I had not the opportunity of listening to Mr. Dalgliesh's paper; but I have recently perused it, and was entertained with the choice passages from the ancient and modern history of artificial lighting communicated to us by the author. Indeed, I consider that some such title as that would have been more appropriate for the paper than the one which Mr. Dalgliesh adopted; for he does not give us many suggestions as to how illuminating gas may best meet the competition of oil and electricity. Probably he thought that the discussion would supply the deficiency. As a slight contribution to this end, I venture to express the opinion that gas lighting has no competitor to fear, so long as those who have the control and management of gas undertakings aim at the cultivation of what I would call the three graces—Cheapness, Lighting Power, and Purity; and the greatest of these is Purity. Whatever other hindrances stand in the way of the more extensive adoption of gas for lighting and cooking purposes, should be removed. Chief amongst these, I class the deposit system. The adoption of this system at the outset might almost have been a suggestion of the enemy. At any rate, save in very exceptional cases, it ought to be discarded. There is nothing, in my opinion, that more handicaps the extension of the use of gas, and assists the competition by oil, especially amongst the smaller consumers in towns. But all round the practice of enforcing the payment of deposits is a most objectionable one. I candidly confess that if I had it to pay in my own case, I should look upon it as a reflection on my honesty or my credit, or both, and would refuse to comply with the requisition. Under a prompt and efficient system of collection, there is no need for the deposit system."

Mr. W. WOODWARD (Bury) said there could be no doubt that they did owe an apology to Mr. Dalgliesh for the neglect with which they had treated his paper; but in some respects Mr. Dalgliesh was himself to blame, for he had submitted two or three sets of statistics, and the Committee might be excused for diffidence in bringing the matter forward under the circumstances. There was no doubt in his mind that the great obstacle to the increased

consumption of gas was its price. They found in Bury that, by reducing the price to slightly under 2s. per 1000 cubic feet, they had recovered consumers who gave up the use of gas six or seven years ago. Although they had lost one or two large consumers, their consumption had increased 2 million cubic feet a month since they reduced the price of gas. This went to prove that the price had much to do with consumption; and he was assured by pawn-brokers in the town that, if they were willing to take them, they could have their shops simply flooded with oil-lamps. Oil was at a discount in Bury at present. He considered the meter-hire system an injustice altogether. It was absurd to charge customers for the instruments by which they measured the gas. They had neither deposit system nor meter-hire at Bury; and this year they had an increase of more than 10 per cent. in the consumption, whereas in other years they had had a decrease.

Mr. T. B. BALL (Rochdale) observed that, although he agreed with Mr. Woodward that the reduction of the price of gas to a minimum was the best means of competing with oil and illuminants of that description, he did not agree with him altogether that this would to any appreciable extent bring back consumers who were lost to the gas company or the corporation. Nor was he altogether sure that, if it would, it would be an unmixed gain. A great deal had been heard lately about small consumers. In Rochdale they had a considerable number of small consumers. The population was perhaps 70,000; and they had nearly 20,000 meters in use. Of these 83 per cent. were two-light meters, which was tolerably conclusive evidence that they had a great many small consumers; indeed, it was an exceptional thing for property to be erected in the town without the gas supply being put in. The fittings were put in, and the meters supplied by the landlord; they had not a single meter belonging to the Corporation. This, as he had said once before, was a great evil; but it removed at any rate the difficulty sometimes put forward, of the expense incurred by small consumers in procuring these things. And yet, with this advantage, and with no expense whatever to be incurred—they could have the gas turned on at will—the people still preferred oil; and the quantity of gas they would burn under any circumstances was exceedingly small. In many cases it did not exceed 2000 cubic feet per annum; and the cost of inspection and collection on that amount would certainly not be less than 1s. per 1000 feet. The inspector went eight times a year; the collector probably had to go another eight; and there was all the expense of book-keeping for the 2000 feet, exactly as there was for a consumption of 200,000 cubic feet. Altogether, he was not at all sure that the small consumer was such an acquisition as some appeared to suppose. The prompt collection of accounts was stated to be one method of counteracting the difficulty these people experienced in getting together 3s. or 4s. at the end of the quarter; but if they were to spend another shilling per 1000 cubic feet in collecting these small sums, it became a losing, instead of a profitable business. He quite agreed with the recently-expressed opinion of Mr. Hunt, that they must look at these things after all from a commercial point of view. It was no use attempting to sell gas in quantities of 2000 cubic feet per annum if the transaction ended in loss. They would not be any better off for any amount of that business; and this, after all, appeared to be the rational view to take of it. Everything, he thought, had been done at Rochdale, except the collection of accounts at short intervals, to encourage consumption. Whether even the plan of frequent collection would bring these people back to burning gas, he must take leave to doubt; and he also doubted whether they would be very great gainers by the transaction even if it did.

Mr. W. W. HUTCHINSON (Barnsley) observed that the competition of oil and other illuminants had to be met in the course of their business; and it was necessary to know the best means of dealing with it. He believed that if means could be taken to induce all property-owners to put in gas-fittings, one reason for the non-consumption of gas would disappear. As it was, the few shillings which it cost to put fittings in a cottage house formed an insuperable bar with many people to the use of gas. Though these small consumers might be rather troublesome and expensive in the matter of the collection of accounts, and might not be a source of much profit, they were nevertheless a stable source of consumption, and were not liable to much change. It, therefore, seemed to him desirable to stimulate this branch of the business. Oil-lamps could be obtained at an almost infinitesimal price—for about 1s. each; and then the consumers of oil had the advantage of the weekly payment system. The cart went round with the oil; and the weekly payments were so low that the sellers of gas could not very well adopt the system, and collect such small amounts. He was afraid the attempt to meet the competition of oil in these cases by weekly collections would not pay. The adoption of prepayment meters might afford a means of overcoming the difficulty; but whether there was a prepayment meter in the market sufficiently reliable for the purpose, he was not just then prepared to say.

Mr. J. BRADDOCK (Radcliffe) remarked that his experience was that the small consumer might be depended upon to take about 4000 cubic feet of gas per annum, which was double the quantity named by Mr. Ball.

Mr. A. SHIRES (Biddulph) said it did not invariably happen that an increase in consumption followed a reduction in the price charged for gas. He had only obtained five new customers as the result of a recent reduction; and he did not know that all these would pay him. As to fortnightly or weekly collections, he could

not say that he was much enamoured with the idea. A certain class of cottage occupiers would not pay; and if they were to go for the money fortnightly, they would appear to be praying and begging for it in a way which would not be pleasant.

The PRESIDENT said that in Darwen they had reduced the price of gas, in addition to taking away some restrictions; and since he mentioned this matter in his Inaugural Address last February, 700 or 800 cottage-meters had been connected—the result being that the consumption of gas was 15 or 20 per cent. more than last year. They expected, of course, that there would be some increase of the loss through bad debts; but still they obtained a stated consumption, which was going on continuously. As they had enlarged their works, they could produce the extra gas required; and the standing expenses were just the same whether they had this additional consumption or not.

Mr. BALL inquired whether the President could say what proportion of the increase was due to the old, and what to new consumers?

The PRESIDENT was afraid he could not answer that question correctly; but taking the increase at 15 per cent., he should say that certainly from 5 to 7½ per cent. of the increase came from houses where they formerly had gas, but at which they were not consuming it previous to the reduction in the price. The rest of the increase was from new houses and new mills; but he estimated that, at any rate, from one-third to one-half of it was from old property. He was in the same difficulty as Mr. Ball with respect to the meters, which in most cases belonged to the consumers, or the owners of the property. It seemed to him a remarkable state of affairs. None of them, if in business as grocers or drapers, would ask the customer to bring his own scales or his own yardstick; but in this matter of the sale of gas, gas companies had, practically speaking, done this. In his opinion, the practice was totally indefensible; and it certainly had been one of the drawbacks to obtaining consumers. So far as the internal fittings were concerned, the houses in Darwen were like those at Barnsley, referred to by Mr. Hutchinson. No one thought of building houses without putting gas-fittings in; and he did not want anyone to get into the habit of doing so, because, the fittings being in, they certainly had gone a long way towards getting a consumer of gas when a tenant came into the house. Mr. Ball had told them that, with a population of 70,000, he had 20,000 meters. That certainly appeared to be a very great proportion; and they had nothing like it in Darwen. It would seem, as Mr. Ball said, as if they had a meter in almost every house in Rochdale, and perhaps more than one on some premises. The information which Mr. Dalgliesh had collected would be valuable for reference. He could not say that the whole of it was strictly correct, because, as Mr. Dalgliesh explained, he had had to take for granted certain bases for calculation. In Darwen a calculation based on the population did not work out correctly. The preparation of the table must have involved a great deal of trouble; and he hoped it would be found useful.

Mr. C. W. HASTINGS (London) asked whether the President meant to say that the houses in Darwen were provided with chandeliers and brackets, or only lined with pipes.

The PRESIDENT replied that a place was left for the meter, and pipes were laid to the centres of the ceilings, or to the walls in every room of the houses, except perhaps the attics; and brackets and one or two light pendants were fixed.

Mr. HASTINGS said this was a thing they did not experience in the South at all.

The PRESIDENT remarked that it was very general in Darwen the gas-fittings being included in the architect's specifications for new houses.

Mr. N. MEIKLEJOHN (Longwood) said that the sum of 1s. per 1000 cubic feet which Mr. Ball mentioned as the cost of inspection seemed to him an absurd amount. In his (Mr. Meiklejohn's) case, it would come on this basis to more than £1500, as about 80 per cent. of the meters in his district were two-light meters; and the £1500 would be more than the total of his gross profit.

Mr. BALL explained that he did not mean to say that the cost of inspection alone would be 1s. per 1000 cubic feet. He meant that the cost of inspection, collection, book-keeping, expenses of the accountant's department, and bad debts would come to 1s. per 1000 feet for these small tenement occupiers.

Mr. DALGLIESH confessed that the discussion had not been so extensive as he thought it would have been; and as no doubt it would have been if it had been taken earlier. He could quite understand that the subject had gone out of the minds of members, as a good part of it had escaped from his own. He was sorry Mr. Newbigging was not there to give expression to what he had been pleased to write. The only fault he seemed to find was that he (Mr. Dalgliesh) might have called the subject of his paper "Artificial Light," instead of "Oil and other Illuminants." If the members read the paper carefully, they would find that he dealt pretty largely with the production of oil, both in regard to its manufacture from shale in Scotland, and as about it being obtained from the natural wells of America and Russia. He also showed the commercial and financial position of the oil industry last year. So, with all deference to Mr. Newbigging, he thought there was ample justification for the title. He also referred in the paper to electricity. Some of them—himself amongst the number—had to compete with it; and the result had been to prove that it was not so much electricity they had to fear as the consumption of oil, which was retailed in small quantities. As to Mr. Woodward, if he had known the facts, he would not

have committed himself to the statement that he (Mr. Dalgliesh) had issued two or three sets of statistics. He had never altered a single figure. He explained once before that, in the table, the consumption per mile of main was substituted for the capital. He wished to correct this, but was not allowed to do so; and this being the case, he had to go to the expense of having slips printed showing the figures in their correct form. Under these circumstances, he ought not to be charged with having altered a single statistic; and possibly if Mr. Woodward had known the facts, he would have been a little more charitable. He thanked Mr. Ball for his temperate remarks, all of which he agreed with, except in the statement that cottage consumers only took 2000 cubic feet per house. He (Mr. Dalgliesh), had the misfortune to be in a wide district where the consumption was very small; but he found that the cottage consumers burned more gas than Mr. Ball mentioned. He also considered the statement as to the 1s. per 1000 cubic feet was over-estimated. The great evil in many towns where they were supposed to be supplying dear gas was the extent of the district, and the unprofitable length of the mains. His own was a case in point. They had 66 miles of mains, with a consumption of 773,843 cubic feet per mile. The average of the United Kingdom (as worked out from the official returns) was 4,114,000 feet per mile of main; but if they could only get it in places like Glossop to two or three million feet per mile, undoubtedly the companies and corporations would be glad to bring down the price materially. He agreed with what certain speakers had said in regard to gas-fittings. The fault was not in some cases so much dear gas as bad fittings. It was a great mystery to him how some of the fittings in Glossop could be termed "fittings" at all. In nine cases out of ten, in the old fittings of houses, there was nothing but ¼-inch piping hung like ropes, without the slightest attempt to make a gradual fall to the meter. With the slightest disturbance, these fittings got out of order; and the people refused to do anything towards repairing them. There were at least a hundred houses in the town in that condition to-day. He hoped the statistics he had prepared would be useful. The best guide would be found to be the consumption per mile of main. Whatever differences there might be in the consumers or the population, the consumption of gas per mile of main was a true indication of the position of a company or corporation.

The PRESIDENT remarked that the duty of passing a vote of thanks to Mr. Dalgliesh was discharged at a previous meeting.

The members next proceeded to discuss the paper read by Mr. T. Newbigging at the preceding meeting, entitled "Gas-holders without Upper Guide-Framing." A report of the discussion will be given next week.

SOCIETY OF ENGINEERS.

The Thirty-fourth Annual General Meeting of this Society was held yesterday week at the Rooms of the Society, No. 9, Victoria Chambers, Westminster, S.W. The chair was occupied by Mr. A. T. Walmisley, the President. The following gentlemen were duly elected, by ballot, as the Council and Officers for the ensuing year:—President, Mr. Jonathan R. Baillie; Vice-Presidents, Mr. Henry Adams, Mr. R. W. Peregrine Birch, and Mr. William Newby Culum; Ordinary Members of Council, Messrs. Chris. Anderson, James Henry Cunningham, George A. Goodwin, Robert Harris, James William Restler, William Schönheyder, William Andrew Valon, and Joseph William Wilson, Jun.; Honorary Secretary and Treasurer, Mr. Alfred Williams; Honorary Auditor, Mr. Alfred Lass. The proceedings terminated with a general vote of thanks to the Council and officers for 1888, which was duly acknowledged by the President.

On Wednesday the annual dinner of the Society was given at the Guildhall Tavern; the general arrangements being most efficiently carried out by the Secretary, Mr. G. A. Pryce Cuxson. The President, who occupied the chair, was supported by Sir Robert Rawlinson, K.C.B., Sir Edward Herslet, C.B., Sir Philip Magnus, and by most of the Council named above. Among other members of the Society and visitors were: Messrs. Jabez Church, Charles Gandon, and R. P. Spice, Past-Presidents; and Messrs. R. L. Andrews, Hubert T. Bailey, A. F. Broadberry, James L. Chapman, Samuel Cutler, John Gandon, Henry Gandon, W. H. Hardy, Joseph Manwaring, M. Mildred, Charles M. Ohren, H. F. Packham, W. Porteous, W. Syms, S. Tamburini, J. Tysoe, and James Watson. In proposing "Success to the Society of Engineers," the President stated that the Society has now been in existence for more than one-third of a century; and notwithstanding the fact that kindred professional bodies exist, having somewhat similar objects, the Society continues to increase in numbers. The main object of the Society has always been to benefit the younger members of the profession; principally by visits to works—a privilege which forms one of the chief benefits of membership in the Society. He added that it was incredible to anyone who had not made the experiment, how much more might be learnt by the comparison of ideas, when conversing together in a body while examining work in progress, than when left alone simply to inspect. Various papers have been read during the past session by eminent authors at the ordinary meetings; and, in his opinion, no just critic of the Transactions could charge the Society with a want of freshness in the papers read, nor with a desire to exclude subjects profitable for discussion. The toast was responded to by Mr. Alfred Williams.

Register of Patents.

WATER-METERS.—Pauwels, J. C. W., of The Hague, Netherlands. No. 15,306; Nov. 9, 1887. [6d.]

This water-meter consists of a cast-iron box (preferably of elliptical shape) formed of two flanged pieces connected together in any suitable manner. Inside the casing is arranged a wheel, square shaped in cross section, and having the form of a hollow ring furnished with a groove for the purpose hereafter described. Within this wheel revolve a number of spokes, arms, or ribs, connected to a central axis, and provided with fans at their extremities which project within the groove into the wheel. The latter carries at each end a pipe leading outside the case; one an inlet, the other an outlet for water. The central axis is connected with registering mechanism to which the patentee lays no claim.

Fig. 1 is a side view in perspective of the meter; and fig. 2 a perspective of one-half of the meter, showing the inside mechanism.

R is a ring fixed to the half box shown in fig. 2 by means of straps, and having a square cross section or ends as shown by the inlet I and the outlet O, both of which are furnished with pipes P as shown in fig. 1. The spokes of the fans pass through a groove formed in the ring R. A is the axle communicating with any suitable registering mechanism arranged in the box B. When water is admitted to the meter, it enters at I, travels through the ring R and causes the fans to rotate and the axis to revolve and to register the amount of water flowing through it.

REGENERATIVE GAS-BURNERS.—Lamb, G. W., of Peckham Rye, London. No. 16,982; Dec. 9, 1887. [8d.]

The object of this invention is to arrange the burner portions of regenerative gas-lamps so that "a great intensity and brilliancy of flame is produced and the maximum of flame more rapidly obtained."

Fig. 1 is a sectional elevation of the lamp with the gas supplied in a downward direction; and fig. 2, in an upward direction.

The patentee employs one tube or casting only, and forms the upper part B with holes so that gas is supplied in minute streams to the interior C where it impinges against a baffle-plate of gauze to charge a lower chamber at a uniform pressure for consumption at the lower part. It is here deflected by a button F into a circular sheet of flame; the flame striking against a ring-plate G secured to the air supply-tube. The air, after passing through a sheet of gauze, acts upon the top surface of the ring of flame, and causes it to spread to the outer edge of the ring plate so as to enable the full lighting power of the gas to be obtained with perfect combustion. The exterior of the flame is supplied with air by the perforations in the rim which carries the glass. The gas-supply tube is open at its lower end; but the button or spreader F is secured to a central stem which is adjustable to regulate the opening or ring slit from which the flame emerges. The products of combustion pass up the passages N to the chimney or outlet, within which the gas-supply pipe is arranged. The heat from the products of combustion thus raises the temperature of the gas while descending the pipe; and from the heat imparted thereto from their proximity to the flame, the gas is heated to great intensity before it gets to the point of consumption.

When the gas is fed upwards, as in fig. 2, a stem or branch is connected to the upper end of a bracket, pedestal, or other ordinary supply to a burner, arranged so that the gas is furnished in minute streams to a chamber C, and from thence to the button or spreader F, which is arranged so that the gas issues in ring form and is spread still further by the ring G before mentioned.

ENRICHING GAS.—Lawrence, R. S., of Philadelphia, U. S. A. No. 17,676; Dec. 23, 1887. [1s. 3d.]

This is an improvement on patent No. 16,992 of 1886—an automatic gas carburetter—which has been purchased by the Lawrence Gas Company, to whom several references have been made in the JOURNAL.

The illustration shows, in central vertical section, a carburetter

according to this invention; certain parts of it, however, being shown in elevation.

The generator (made of copper or other suitable material) is packed with any absorbent material such as short-cut coarse "Excelsior," as are also all but the uppermost of the distributing pans hereafter described. [As is well known, says the patentee, "Excelsior" is a material consisting of curled shreds of wood, and which is used as a substitute for curled hair in stuffing cushions and the like.] The uppermost pan contains charcoal to form the bottom of the condensation chamber also hereafter described. On top of the generator is mounted a reservoir B, of the same superficial area as the generator, for containing hydrocarbon. The bottom of the reservoir is made sufficiently strong not to yield under the weight of the hydrocarbon, which is let into it through one of two stopcocks on top; the other cock serving as a vent for the gas which may be conducted back into the supply tank by any suitable connection. Each cock is provided with a short pipe having a screw cap at its outer end, which may be removed when it is desired to attach the connections for supplying hydrocarbon to the reservoir and for conducting away gas or vapour therefrom. In the top of the reservoir a screw-threaded opening O is formed, large enough to admit a man's arm, but closed by a screw plug. C represents a chamber on the top of the reservoir, to be filled with water for sealing the stop cocks and also the opening O, in order to prevent the escape of gas. This chamber is provided with a hinged lid. D is a tube (about 5 inches in diameter) extending centrally from the top of the reservoir to near the bottom of the generator. It is designed to support the pans and also as a container for a portion of the valve-operating mechanism. F is an air-tight copper float surrounded by a wire screen, and connected at one end to a rod which passes up through the tube D, the other end being connected to one end of a lever pivotted within the tube near its top. To the other end of the lever there is connected one end of a right-angled bent rod, which passes through a slot in the tube D, and to the outer end of which is attached a spindle passing through a longitudinally perforated valve seat plug secured in the bottom of the reservoir. The diameter of the perforation in the plug at its smallest part is about three times the diameter of the stem. To the spindle is secured a conical cork valve G, the face of which accurately fits the valve seat in the plug. By this construction of the valve-operating mechanism, the perforating of the top of the reservoir for the passage of the valve spindle is avoided. The upper and lower ends of the spindle are arranged to work through guides secured to the upper and lower sides respectively of the valve seat plug. Thus the valve G, whilst being moved, is kept vertical. There is a cylinder of wire gauze (closed at its upper end) arranged to surround the valve G; and serving to prevent grit or other dirt passing to the valve seat. A pin arranged to work against the outer side of the tube D and at the sides of the slot, serves to prevent the rod moving into the tube D under the action of the weight of its horizontal arm and the valve and valve spindle connected thereto. A funnel-mouthed tube is arranged below the opening in the valve seat plug, and serves to direct the hydrocarbon to the upper tray H. As the hydrocarbon cannot pass over, the reservoirs of any number of carburetters can be filled from a principal supply tank located at a distance from the carburetters. Furthermore, by this construction the valve can be removed through the opening O in the top of the reservoir, and its operating rod be withdrawn through the slot in the tube D.

H represents a series of square pans, about 2½ inches in height and of the full width in one direction of the interior of the generator, to the sides of which they are firmly riveted and soldered. The width of each pan in a direction at right angles to the direction just referred to, is such that the pan does not extend to the adjacent wall of the generator—an opening is left. Alongside this opening there is a dam of a height greater than that of the remaining sides of the pan. The pans are perforated centrally to permit them to be slid down on the tube D, to which they are firmly soldered and by which they are centrally supported. A wire gauze cover extends from the top of the dam in each pan to the side of the generator, to confine the packing in position. The pans are so arranged in the generator that the opening at the side of one is at the opposite side of the apparatus to the opening at the side of the next pan. The top pan not only serves as a distributing pan, but also to hold a layer of charcoal that forms the lower wall of the condensation chamber I, whose upper wall is formed by the bottom of the reservoir. It is found advantageous to use sticks of charcoal consisting of carbonized limbs of wood, carefully selected and (say) approximately 1½ inches in diameter and as long as practicable. One layer of such sticks of charcoal will suffice, says the patentee, if they be placed side by side and held in place by covering the pan with a wire gauze screen having 4 to 8 meshes to the square inch.

J is the distributing pipe located immediately beneath the lowest pan

and supported in position by trestles resting on the bottom of the generator. The bottom of the pipe is perforated; the perforations increasing in size or number in each direction from the inlet, so as to equalize as nearly as possible the distribution of the air or gas. It must be understood that the pressure in the pipe gradually decreases from the inlet inward, as the air or gas reaches each successive perforation. The perforations being in the bottom of the pipe ensure a free escape from all precipitates. L is a perforated plate located in the condensation chamber and secured to the sides of the generator. It is of sufficient thickness to give it rigidity; and is perforated throughout its entire surface for the purpose of dividing the volume of ascending gas into a great number of small currents, and thus distributing it evenly to the upper portion of the condensation chamber, in which are located certain gathering and sub-distributing pipes. The plate L likewise constitutes an efficient scrubber, depositing any excess of hydrocarbon. M is the gathering pipe located close against the bottom of the reservoir, and supported in this position by trestles (like those supporting the distributing pipe) resting on the plate L. This pipe is round, and its bottom is perforated; the perforations being evenly disposed over its entire surface. It is connected with the outlet pipe P. Immediately under the gathering pipe, and supported in the same manner, is located the sub-distributing pipe N; its purpose being to distribute air or gas directly into the condensation chamber, as it is perforated in the same manner as the pipe J.

From different causes (changes in weather, &c.) the temperature is liable to vary in the condensation chamber; and it might well happen, says the patentee, that after working for a time in cold weather, the temperature in the condensation chamber might become so low as to condense too large a proportion of the hydrocarbon vapour away from the gas or air. Then by admitting some gas or air through the sub-distributing pipe into the condensation chamber, the temperature could be raised, since the gas or air so admitted would have a higher temperature than the contents of the chamber. Thus, although a lower grade of gas would then leave the apparatus than that normally produced, yet the quality would be much higher than would be the case if the condensation due to an excessively low temperature were permitted. Not only so, but excessive condensation would be liable to result in the freezing of the vapour and closing of the pipe M, which by the use of the sub-distributing pipe in the manner described may be prevented.

E are pipes for clearing the generator and the pans H of any residuum which may collect therein. The upper ends of these pipes may be attached to a suction pump when necessary. The lower ends pass through openings in the tube D and communicate respectively with the interior of each pan and with the bottom of the tank, as seen in full and dotted lines.

The reservoir being filled with hydrocarbon, the hydrocarbon will flow through the hole in the valve seat plug and into the upper pan, where it will be freed of its impurities by the filtering material. When this pan is filled, the hydrocarbon will flow over the dam in a thin sheet and into the packing below, thoroughly saturating it, and finally into the next pan and so on until the hydrocarbon reaches the bottom of the generator. When a sufficient quantity of hydrocarbon has accumulated in the bottom of the generator to raise the float, the latter will be moved upward; thus raising one end of the lever and lowering the other, and thereby pulling the valve G down on to its seat and shutting off the supply of hydrocarbon. When there has been sufficient evaporation of the hydrocarbon to allow the float to descend, the valve will again open and admit a fresh supply. The air or gas to be carburetted is admitted under pressure to the distributing pipe J, and is forced therefrom through the perforations therein, into the interior of the generator; and owing to the fact that these perforations at points distant from the extreme end of the pipe are larger or more numerous than those in the vicinity in which the pressure is greater, a comparatively even distribution of the air or gas is obtained. On leaving the distributing pipe, the air or gas permeates the packing in the bottom portion of the generator; and then rising, passes through the opening next the bottom pan. It then again spreads out into the packing above, and moves directly across the generator to the opening at the side of the next pan; and so on until it reaches the upper pan, when it passes through its opening and spreads out over the under side of the distributing plate L, and passes through the perforations therein, being thus directed to all parts of the condensation chamber, from which it makes its exit through the gathering and outlet pipes.

The top pan being fitted with a bad conductor of heat—viz., charcoal—and the bottom of the reservoir being covered with hydrocarbon, it will (in the patentee's own words) be "apparent to persons familiar with the manufacture of gas from a volatile hydrocarbons that the chamber between the bad conductor and the reservoir will always be at a very low and uniform temperature while the apparatus is in operation. Thus when the gas reaches this chamber, it is almost immediately reduced to a very low temperature. The temperature of the chamber being below that at which supersaturation of the gas can exist, all excess of carbon is removed, and thus smoke at the burners is avoided. As the gas expands on reaching the outlet, it cannot condense in the service pipes until it reaches a point so cold as to contract it beyond the degree to which it was condensed in the chamber. Supposing ordinary illuminating gas is being carburetted, and it is desired to use burners of the largest size, and avoid all danger of smoke at the tips, it is simply necessary to partially close cock No. 1 and partially open cock No. 2, and admit a quantity of gas direct to the condensation chamber. This results in the production of a gas containing less carbon than if the whole volume had passed through the generator. Now supposing air is being carburetted for illuminating purposes, and it is desired to produce a gas suitable to the particular burners being used—for different styles and sizes of burners are suitable only for different grades of gas—instead of adjusting the burners to suit the gas, the grade of gas is raised or lowered to suit the burners. For instance, if the whole volume of air is being passed through the generator, and the gas is found too rich for the burners, the grade is lowered by admitting the proper quantity of air through the branch inlet pipe direct to the condensation chamber. During the day, when it is desirable to produce gas for heating purposes only, a comparatively small quantity of air is passed through the generator, and the required additional quantity is supplied through the branch inlet pipe. By the various manipulations

of which the apparatus is susceptible, a smokeless flame can be produced ranging in luminosity from 6 to 50 candles."

GAS-GOVERNORS.—Cole, H. W. and A. F., of Stonorport. No. 126; Jan. 4, 1888. [3d.]

Apparatus constructed according to this invention is more especially suitable for regulating the supply of gas to regenerative lamps or other suspended lamps; and it illustrates other modifications of the governors described in patent No. 16,817 of 1887.

Fig. 1. Fig. 2.

In the governor represented in fig. 1, C is an annular projection or wall on the lower portion of the casting; and E, a disc fitting into a rebate formed on the annular wall, and provided with a central perforation. The central perforation of the disc is of such a size as will admit of the valve-tube sliding freely therein, but will not to any appreciable extent permit the passage of the gas between the outer surface of the tube and the edge of the perforation. G is a float, and H a valve closing the lower end of the valve tube. At the valve seat around the tube are formed notches for the passage of gas therethrough; while the projections between the notches serve to guide the lower end of the tube in its vertical movements. When gas is passed in the direction of the arrows, the quantity escaping at its full ungoverned pressure through the hole in the valve tube to the underside of the float being greater than that capable of passing the regulating screw, the float which normally rests on a shelf formed on the annular wall C is raised, and the valve is consequently moved nearer to its seat—sufficient to admit only the quantity of gas which can pass the regulating screw. It therefore follows that as the gas pressure at the outlet side of the regulating screw is maintained equal by means of the free gas passages, and the weight of the tube and its attachments is properly adjusted, any increase in the pressure of gas must first act on the underside of the float, and by raising it close the valve in proportion to such increase; and, in the reverse manner, if any decrease of pressure occur, the valve will be opened in proportion to such decrease, thus ensuring a regular and uniform flow of gas through the outlet.

The construction of the governor represented in fig. 2 is similar to that shown in fig. 1 excepting that the annular wall C forms part of an independent casting. This construction admits of the wall being made of some hard metal. The valve in this case is hollow, and admits of the passage of gas therethrough; the gas being afterwards throttled between the outer surface of the valve and the valve seat constituted by the bottom of the casting C, which is also drilled to communicate with the outlet. The lower edge of the valve is notched to admit of the gas initially passing through it. At the inlet a guard is provided to prevent dust carried along with the gas from entering the governor.

THE POSITION OF GAS ENGINEERS.

SIR,—I am sorry to see a tendency to depreciate the value of the services of engineers and other high officials of gas undertakings. Evidence of this is to be found in the practice, just beginning, of applying to contractors, not only for tenders, but also for plans and specifications of important works such as gasholders—as, for instance, at Leeds, where Messrs. Clayton, Son, and Co., have designed, and have the order for, a large gasholder; and more recently Messrs. C. and W. Walker appear to have done the same for Sydney. Other signs pointing in the same direction, are a remark made to me a few weeks ago by a director of two important companies, that he would back a certain firm to design works against all the engineers; and the action of town councils who, from their acts and discussions, create the impression that skilled engineers are in some cases considered unnecessary, and in others not rightly appreciated.

Now it is an undoubted fact that the great advances made in gasholder design and construction are not due to contractors. Had we depended upon them, very few (if any) improvements would have been made. They would have followed the old lines, and properly so; because it would not have been wise on their part to have introduced innovations on established practice. Had they been so inclined, the greatest difficulty would have been found in inducing boards and committees to adopt their ideas. I can remember one great improvement introduced by a gasholder builder—viz., the late Mr. Joseph Piggott's curved-cup, designed in 1862. Although there was no royalty, he had the greatest difficulty in getting it adopted; and but for the fortunate circumstance that just at the time he had a contract with a company not afraid of novelties, there is no knowing how he could have got it tested.

I have no intention of criticizing the fine holders designed by Messrs. Clayton and Messrs. Walker respectively, though I do not agree with the latter entirely in the principles set forth in the JOURNAL of the 4th inst.; but while cheerfully recognizing the excellence of their work, I must utter a protest against the possible development of the practice. I am quite prepared to admit that contractors can render most valuable assistance to engineers, consisting mainly in suggestions whereby economies may be effected in the use or adaptation of material so that weight and labour may be saved. But it will be a very bad day for the gas industry, if the time should ever arrive when it is thought that skilled engineers and other high-class officers may be dispensed with. The case of Leeds may be referred to, as was done at the Birmingham Town Council the other day, as an argument in favour of low salaries. The Gas Committee of Leeds evidently do not consider their officers capable of designing a gasholder; and to suppose that the low salaries and the low price of gas in that town are in any way connected, is a great fallacy. Leeds was until recently in the hands of one of the ablest men in the kingdom, Mr. H. Woodall, who was not rightly appreciated, and left on receiving an offer of an appointment at about three times the salary he was getting at Leeds. It was his work in the course of a few years that reduced the price of gas, by one-half, to its present low figure of 1s. 10d.; and during the same period he converted the gas-plant from a dilapidated condition into one of great efficiency, at small cost. He showed contractors how to build good and cheap gasholders; and they are now simply adopting the good points in his designs and those of other engineers, to which they have access. But does anyone suppose that gas in Leeds would now be sold at 1s. 10d., and that the works would be in good condition, if he or some other able engineer had not been the manager.

Manchester also was named in the Birmingham discussion, in conjunction with Leeds; but the Manchester Corporation, though paying very moderate salaries to their officers, have (as you pointed out last week) in other ways paid much more for skilled assistance than Birmingham. They gave £1000 in premiums for the ground plans only of their new works, which the expense of adjudicating brought up to probably not less than £1500. To this must be added the cost of making the designs for the buildings and works, and the professional fees paid for carrying them out, which had not after all the great advantage possessed by Birmingham of being designed and executed by engineers interested in making them a success, as is necessarily the case when the permanent resident engineer does this work.

It is universally recognized that Birmingham is well served; and it is gratifying to the profession to find this is understood and appreciated by the Chairman and members of the Gas Committee. If those members of the Town Council who objected to the salaries, knew the extent to which the prosperity of their great undertaking is due to, and in the hands of the principal officers, there cannot be a doubt that they would take the same view of the question.

GEORGE LIVESEY.

Tunbridge Wells, Dec. 15, 1888.

TESTING METERS *IN SITU*.

SIR,—In the JOURNAL for the 11th inst., there appears a paragraph referring to the testing of gas-meters *in situ* in dwelling-houses in Dublin, now inaugurated and mentioned as a success. Will you allow me to make a few remarks thereon? A similar wish has often been expressed here for meters to be tested without the trouble and expense of forwarding them to the Standards Office.

The testing of meters generally—like weights and measures—*in situ*, cannot be a success, if inspectors are to be “a law unto themselves,” and the Sale of Gas Act treated as a secondary authority; for sections 12 and 13 of the latter give plain directions or rules for testing, and section 11 states that a “fine not exceeding £5 for unlawfully acting,” or in “breach of any duty imposed upon him by this Act,” awaits him. Seeing, then, the testing of meters *in situ* generally cannot be done so as to comply with the rules laid down—as I will hereafter show—where is the legal value of the test, and what confidence can it give to either seller or buyer of gas?

Only in the exceptional case of large and heavy meters, such as our mills and warehouses possess, can a test *in situ* be justified; for such meters are with difficulty removed (fenced about, as they often are, with brick and masonry), and the expense would be no small matter also.

But even in such a case, the test cannot be a satisfactory one, and but an approximation to legality. The first requirement in testing meters is pressure as a test for soundness or leakage. The Act prescribes 3 inches; but for an average day pressure, I suppose 1 inch would only be found in the main. The test for percentage of error requires 5-10ths as the maximum pressure; but how many meters fail to work at this pressure, but work at 10-10ths? In the testing-room, such a meter would be rejected; but tested *in situ* it would escape.

Again, as regards speed, or the rate per hour the standard meter will pass gas to prove the capability of the meter to be tested, to deliver its legal number of cubic feet per hour. The small standard 20-light, at 5-10ths, delivers 120 cubic feet per hour; but in testing by this standard, say, a 50-light=300 cubic feet per hour at 5-10ths—if this legal pressure is found in the main—it would fail to supply the volume of gas required in a given time, and hence the test would be futile.

In testing domestic meters, where the small standard—20-light—is too small, the large standard—100-light—would often be found too large to be got into a cellar or basement of a dwelling-house. The meter to be tested has to be disconnected at the inlet and outlet. In parting with the gas in the process of testing, it must be blown into the open; hence, here is an element of danger. To burn the gas through the fittings in the usual way, would probably check the flow and lessen the rate per hour below what it should legally deliver at. I have not referred to the question of temperature (water and gas), which is equally important.

The foregoing will show what unreliable and illegal results follow from testing *in situ* generally. The question of remuneration follows; and not the least either. The fixing together of the standard with its complex fittings, filling with water and emptying of the same, the connections to be made with the service-pipe and the meter to be tested, and the care to be exercised to have all “as tight as a drum,” are matters requiring much skill and time; and if the meter in question is a 5-light, the charge is only 1s., if a 10 or 20 light, then 2s. What a liberal fee for a legal decision! For remember, the inspector's certificate produced in Court influences the verdict for seller or buyer as the case may be.

Manchester, Dec. 14, 1888.

JAMES URQUHART.

THE WATER SUPPLY OF THE WAKEFIELD OUT-TOWNSHIPS.—It is reported that the Rural Sanitary Authority of the Wakefield Union have arranged with the Corporation of Dewsbury for a supply of water for several large townships just outside Wakefield, at the rate of 6d. per 1000 gallons. The Wakefield Corporation offered to supply the same districts at 9d. per 1000 gallons from their new scheme of water-works, which has entailed so vast an outlay of the ratepayers' money.

SUTTON-IN-ASHFIELD GAS SUPPLY.—At the last monthly meeting of the Sutton-in-Ashfield Local Board, on the recommendation of the Gas Committee, it was resolved that the scale of charges for gas in future should be: To consumers of 20,000 cubic feet and under, 3s. 5d. per 1000 feet; between 20,000 and 50,000, 3s. 4d.; between 50,000 and 100,000, 3s. 3d.; and over 100,000, 3s. 2d.; and to places outside the parish, 3d. extra per 1000 cubic feet throughout. As £5000 of the gas-work's debenture stock will fall due in January, it was resolved to offer the same at public auction. Mr. Bonser, in the course of the proceedings, said that with the revision of the scale of charges, they stood to lose £300; but it was thought that the reduced price would induce more persons to use gas. In Sutton there were 2040 houses, and only 519 consumers of gas; whilst at Kirkby there were more than 600 houses, and only 104 consumers. He further announced that the reduction would take place as from the 25th inst.; and he thought that only one town in Nottinghamshire was offering gas so cheaply, and that was Nottingham.

THE STRETTFORD GAS COMPANY AND THEIR CUSTOMERS.—At the Sale Petty Sessions on Monday last week, Mr. J. Richardson, made an application, under the Gas-Works Clauses Act, 1871, to obtain a Justices' order for the appointment of some “competent and impartial person” as gas examiner for the parish of Ashton-on-Mersey and the townships of Sale and Timperley. Having put in a petition signed by various consumers, he said that, so far as the Stretford Gas Company were governed by the general law, it appeared to him that, if they elected to come into Cheshire with their works, they ought to have in Cheshire a proper place to test the gas; and it would be for the Bench to say whether they would order a place to be erected to enable the inhabitants of the district to have the gas tested. The Bench doubted their right to make any such order. Mr. Newman, on behalf of the Company, submitted that under their Special Act Mr. Richardson was bound to apply to two Justices in Lancashire; so that these proceedings really ought to have been taken at Strangeways. He contended, however, that the Company had complied with the Act in having a testing station and experimental meter at their works. After a long argument, the Chairman intimated that the Act was permissive; and the Bench thought they would be foolish to make the order without hearing witnesses, so as to learn what the complaint was.

LECTURE ON GAS MAKING AT HEYWOOD.—Under the auspices of the Heywood Congregational Young Men's Society, a lecture was given, on Tuesday, the 27th ult., by Mr. J. Jakens, Consulting Chemist, of Bury; his subject being “Gas Making.” The lecture was illustrated with plant and diagrams. Mr. H. Hawkins, the Corporation Gas Engineer, who presided, said gas making concerned every ratepayer; and the Gas Committee of the Corporation were always anxious that the consumers should know everything in connection with the gas they burned, and the best means of burning it. They had in oil a great competitor; its main advantages being that it could be procured in small quantities and paid for on delivery. Gas was supplied on quarterly accounts; and he regretted that many cottage consumers did not make that provision for payment which they might. If cottagers would put by every week as much as they spent in oil, they would find that gas was 25 per cent. cheaper than oil or candles. Occasionally lamps exploded from causes over which the consumers seemed to have no control, or from a little negligence. If the wick did not reach to the bottom, the lamp would have a tendency to explode. In the course of his lecture, Mr. Jakens advocated the use of gas for cooking and heating purposes. No less than 30,000 feet of gas could be produced from a ton of coal for heating purposes against 10,000 feet for illumination. Gas-fires in houses, instead of coal fires, would be more cleanly and comfortable. In Bury gas was cheaper than coal for heating purposes. Oil gave off as many impurities as gas, with the exception of the sulphur compounds. In closing the proceedings, the Chairman said he looked upon the electric light as the illuminant of the future. Gas would no doubt be used as a motive power and for heating. He believed the time would come when houses would be built without chimneys; there would simply be flues through the walls to carry off the products of combustion from gas fires and stoves.

Miscellaneous News.

CONTINENTAL UNION GAS COMPANY, LIMITED.

The Ordinary General Meeting of this Company was held last Tuesday, at the London Offices, 7, Drapers' Gardens, Throgmorton Street—Mr. H. MCLAUCHLAN BACKLER in the chair.

The SECRETARY (Mr. F. W. Himing) read the notice convening the meeting; and also the following report of the Directors:—

The Directors have to report that at the two stations which are the direct property of the Continental Union Gas Company—viz. Messina and Montargis—there has been some increase in both the public and private lights.

At Messina the reduction in price of gas, which had only been in operation about three months at the date of the last report, has since had time to bear fruit; and a marked improvement in the private consumption, as compared with two years ago, is now manifest.

The Cholera which broke out at Messina with great virulence in the autumn of last year, and the effect of which was to still further reduce the profits, gradually subsided, and has now entirely disappeared.

The outlay on capital account at these two stations during the period under review was £585, chiefly for new mains, lamps, and services, sulphate apparatus, &c.

With regard to the Union des Gaz, the total outlay on capital account at the 13 stations which constitute the property of that undertaking, amounted, during the working year 1887-8, to £53,800, nearly half of which was expended in extending the Milan works. This was rendered necessary by a reduction in the price of gas there resulting in largely increased consumption. In consequence of this reduction the right has been secured to continue to supply gas at Milan until the year 1925.

The dividend received on the Continental Union Gas Company's investment in the Union des Gaz was the same in 1887 as in the previous year.

The following information regarding the working of that Company's stations will also be interesting to the shareholders:—The net increase in the number of lights during the year 1887-8 was: Public, 352; and private, 23,359. The quantity of gas sold shows an average increase of more than 7 per cent. The cost of coals per ton was 7d. more than in the previous year. The total amount of bad debts incurred and written off was only £433. The average price received for the coke shows an increase of 1s. 3d. per ton; while that for the tar shows an average decline of 6d. per ton, but this product is now being disposed of on better terms.

The Union des Gaz carry forward an undivided balance of £23,984, which, added to the special reserve account of £32,400, makes a total of £56,384 available, in case of need, for equalizing dividends in that Company.

Reverting to the affairs of the Continental Union Gas, the debenture debt of this Company stood in the balance sheet at £3100 on the 30th of June last; but the Directors are glad to be able to report that it has since been entirely paid off.

After making all the usual charges and reserves, the net profits of the Continental Union Company for the year amount to £116,867 1s. 5d.

The available sum to the credit of general revenue is £149,694 16s. 10d., out of which the Directors propose to declare a dividend at the rate of 13 per cent. per annum on the ordinary shares; being an increase of 1 per cent. on the previous year. The 7 per cent. preference shares participate *pro rata* in all ordinary dividends exceeding 10 per cent., and will therefore yield 10 per cent. for the year.

After deducting the interim dividend (paid in July last) of 5 per cent. on the ordinary and 3½ per cent. on the preference shares, the balance of 8 per cent. on the former and of 6½ per cent. on the latter, all free of income-tax, will be paid on the 4th of January next. The amount carried forward to the new account will be £35,159 0s. 10d.

The Directors are pleased to be thus justified in congratulating the shareholders on this prosperous state of affairs—a prosperity which they may reasonably hope to see maintained in the future.

The Congress of the Société Technique of foreign gas engineers having been held this year at Boulogne, The Gas Institute took the opportunity of inviting its members to extend their journey to London. The Directors of this Company had thus an opportunity of personal communication with their Managers, and availed themselves of it to the satisfaction of all concerned.

The Board regret to have to announce the loss of one of the original Directors of the Company—Mr. W. White—who died on the 21st of April last, and whose long and earnest services were highly appreciated by them. They have appointed Mr. Tendron (for many years an Auditor of the Company) to replace him.

The vacant auditorship has been filled up by the election of Mr. Eastman. The Director who retires by rotation is H. M.L. Backler, Esq., and the Auditors (Alfred Hersee, Esq., and A. T. Eastman, Esq.) also retire. All, being eligible, will be proposed for re-election.

The CHAIRMAN: Gentlemen, you have heard the report and accounts read; and you see how favourable they are. In commenting upon them, I will first of all take our own two stations—those stations which are our direct property—Messina and Montargis. You have seen how badly we were affected at Messina by the cholera—to such an extent that for a time it almost deprived us of our revenue. I am glad to say that this has entirely ceased; and we are now in a better position than we were before it took place, because the reduction in the price of gas which we consented to under the circumstances which I explained at the last meeting, has been productive of a great portion of the advantage which we expected from it, and which we shall ultimately secure. There can be no doubt of that. Now, I believe Messina will be a growing station—that is to say, it will bring a better revenue than it has done in the past; and for this reason, that the price of gas was really too high there. I thought so myself for some time; but the difficulty was how to give way without getting something in return. You will recollect that we did get something in return for the reduction in price, by obtaining from the Municipality an undertaking that all projects of electric lighting should be suppressed during a period of seven years; and I thought, during this period, we should take the opportunity of pushing the consumption of gas by reducing the price—the temptation being considerable to the consumers, who hitherto had been deprived of the use of gas by the high price at which we supplied it. Montargis has done fairly well during the year; we have no reason to complain of it. Having mentioned our own two stations, I will now pass on to make a few remarks on those of the Union des Gaz. The coal cost more than in the previous year; and for this cause: That the means of conveyance on the Italian railways are, at certain seasons of the year, so restricted, owing to the great traffic for which the railways are not yet fitted, that we experience considerable difficulty in getting coals from the ports at which the ships are discharged (almost entirely at Genoa) to the different stations we have in Italy—Milan, Parma, Modena, and Alessandria. Such, being the case, a certain number of waggons are allotted to the principal shippers of coal at Genoa; and we get our allotment in proportion to the accommodation which can be afforded. But it was not sufficient for our consumption, although we had laid in a large stock at Milan, which is the chief station to be supplied. In order to provide coal, at Milan principally, we were obliged to obtain a transfer of waggons allotted to the coal merchants who were sending coals to Milan, and who had these waggons allowed them as their proportion. We were obliged to buy the coals also which were loaded on the waggons. The consequence was that the coal merchants in Italy, who, like their brethren in England, do not do business for nothing, obliged us to pay them pretty well for the accommodation which they afforded us under these difficult circumstances. This is the reason why coals have been more expensive. Coal, as you are aware, is now rising in price; but I do not think we shall feel the effect of this very much, because we have coal contracts running over three years, and our freights are also secured for some time on favourable terms. Of course, when the contracts terminate, we shall have to run the chance of the markets, as

others must do. I am glad to say with regard to coke that we have reconquered the disadvantage under which we suffered with respect to coal; and we have, owing to the long winter which we passed through, and which seems likely to be repeated to some extent this season, managed to sell all our stocks everywhere, and at prices which are remunerative, and which enable us to annul the effect, as I said before, of the high prices of coal. Tar has recently improved in value; otherwise, during a portion of the year, it was not selling on such good terms as previously. I think we have now got over the difficulty, and shall be able to realize—we are, in fact, at this moment realizing—better prices than we did during the period with which we are making a comparison. The Milan concession, you observe by the report, has been modified to a considerable extent; and we have now got the contract extended to the year 1925. This is a very important advantage to us for a place like Milan; and we feel that it adds materially to the value of our interest in the Union des Gaz. The concessions, by the extension of this contract at Milan, have been raised in average length from 25 years—at which they stood last year, and from which, without this taking place, they would have been reduced to an average of 24 years—to 26 years; the longest being for 45 years. The gas-rental—I am still speaking of the Union des Gaz—has been increased by £16,522, or 4½ per cent. This is a very fair percentage; but the gas sold has been increased in a large ratio—that is, 7½ per cent.; and the reason why, while we have sold such a large excess in quantity of gas, we have received a smaller proportion in rental, is the various reductions of price to which we thought it wise to assent in the several towns, in order to conciliate our consumers, and to offer them the inducement to remain with us rather than go over to our competitor the electric light. We have succeeded as far as we expected to do in the matter. I will now pass on to our financial position with the Union des Gaz. You will recollect that we are holders of exactly 37,000 out of the 50,000 shares of that Company; and the market value of these shares has considerably improved since last year. We take the quotations of the Bourse of Paris, as recorded in the financial returns; and we find that the improvement is £58,000—that is to say, the market value of the shares we hold was last year £58,000 less than this year. This is the increased profit, or increment of value, of our holding in the Company; but you know we do not take that into account in our profits; this merely shows the stability of the Union des Gaz. If we were to add the increased market value of the shares this year, and the value were to fall, we should have to write it off the next; and we might perhaps pay you 20 per cent. this year, and be obliged to pay you only 14 or 15 per cent. (which I hope we shall some day be able to do) the next. We have the shares in our books at the price we paid for them—that is, the par value, £20 per share—representing a sum of £740,000. The market value of these shares represents a total sum of £1,908,000, at the present prices quoted on the Bourse; and consequently the investment we have in the Union des Gaz shows a total profit of £1,168,000, or £58,000 more than last year. (Applause.) That is very satisfactory to me, and so it appears to be to you, gentlemen. The stability of the Union des Gaz is also shown by the amount of their reserves. They have altogether reserves amounting to £378,514; and £35,990 has been taken out of the profits of the last year as an addition to the amount which stood to the credit of these reserves in the previous year. I think I may now take leave of our investment in the Union des Gaz for the present. You will clearly see what a satisfactory investment it is for us; and you will see whether or not we were justified in paying a considerable sum for the goodwill. The sum which we paid for that is now entirely extinguished. We have written it off in the course of years, little by little as our finances permitted; and although it is such a valuable property, it now stands in our books at par—that is *nil* for the extra commercial value of it. I will now revert to the Continental Union Gas Company, and just remark that, as you have heard in the report, the amount of the debentures has been entirely wiped off—we do not owe a farthing on debentures. The amount, which was originally £218,000, has been liquidated by small sums from year to year. There are few companies in this position—entirely free from debt of any kind. Now, the sum which we annually set aside for the writing off of these preliminary expenses having ceased during the past year, we were able to take into account the subject of increased dividend; and we are able to pay you an extra 1 per cent., which we now declare, owing to the cessation of this charge on our profits. The charge last year was something over £12,000; and we therefore declare this increase of 1 per cent., which will amount to £9272, and, in addition to that, we add to the undivided balance of profits £2331. This makes the undivided profits in the Continental Union Gas Company £35,159. If we did not leave a farthing over; if we had no reserve of undivided profit in this Company, we should still be in a first-rate position as to reserves, owing to the large one made by the Union des Gaz. However, we wish to be as prudent as we possibly can, in order to secure ourselves in every way; and therefore we have got this “nest-egg” of £35,159, which will enable us to keep up the dividends if it were necessary to do so at any time, or appropriate it for any other purposes we consider desirable. I will now merely refer to one or two matters which have occurred during the year. One is the visit of the Société Technique du Gaz to this country. While we are prosperous ourselves, we wish to show good-feeling towards our *employés*, and all who serve us so well; and we seized the opportunity of the Société Technique coming over to England, and being well received everywhere, to invite them, in conjunction with the Imperial Continental Gas Association and the European Gas Company, to a dinner at the Crystal Palace; and we did this in the best style—we did not spare expense. We were very glad to have the opportunity of showing the good-feeling we entertained towards them; and which we believe to be reciprocal towards us. There is another matter to which I must refer; and I do so with very great sorrow, because Mr. White, my former colleague, had been a friend of mine for 40 years. In losing him, I feel that it was indeed a very great loss; for he was ever ready to give us his vigorous assistance under all circumstances. Mr. White was an original Director of this Company; and at all times, and especially on occasions of difficulty—for we had to go through a season of very great difficulty and anxiety after the formation of the undertaking—he was a great help, and prevented disasters which might otherwise have occurred. I think, therefore, that Mr. White's memory is entitled to the regret which we deeply feel, and which is, I am sure, participated in by the shareholders. We, of course, sent a resolution of condolence to his family, in which we associated the shareholders. Then there came the question as to who should succeed Mr. White; and we elected Mr. Tendron, one of our Auditors—he having applied for some time to fill the first vacancy. Mr. Tendron is a gentleman who is well acquainted with the accounts and business of the Company; and we felt that we could not do better than nominate him, subject to re-election at the time when Mr. White's term of office would expire. We did so; and we have had the benefit of Mr. Tendron's assistance at the Board for some time; and find that we have done quite right in taking that course. We had also to make another appointment to fill the position vacated by Mr. Tendron; and we elected Mr. Eastman, who is a qualified Accountant, and who was, I believe, the

CONTINENTAL UNION GAS COMPANY, LIMITED.

The Ordinary General Meeting of this Company was held last Tuesday, at the London Offices, 7, Drapers' Gardens, Throgmorton Street—Mr. H. M'LAUCHLAN BACKLER in the chair.

The SECRETARY (Mr. F. W. Himing) read the notice convening the meeting; and also the following report of the Directors:—

The Directors have to report that at the two stations which are the direct property of the Continental Union Gas Company—viz. Messina and Montargis—there has been some increase in both the public and private lights.

At Messina the reduction in price of gas, which had only been in operation about three months at the date of the last report, has since had time to bear fruit; and a marked improvement in the private consumption, as compared with two years ago, is now manifest.

The Cholera which broke out at Messina with great violence in the autumn of last year, and the effect of which was to still further reduce the profits, gradually subsided, and has now entirely disappeared.

The outlay on capital account at these two stations during the period under review was £385, chiefly for new mains, lamps, and services, sulphate apparatus, &c.

With regard to the Union des Gaz, the total outlay on capital account at the 13 stations which constitute the property of that undertaking, amounted, during the working year 1887-8, to £53,800, nearly half of which was expended in extending the Milan works. This was rendered necessary by a reduction in the price of gas there resulting in largely increased consumption. In consequence of this reduction the right has been secured to continue to supply gas at Milan until the year 1925.

The dividend received on the Continental Union Gas Company's investment in the Union des Gaz was the same in 1887 as in the previous year.

The following information regarding the working of that Company's stations will also be interesting to the shareholders:—The net increase in the number of lights during the year 1887-8 was: Public, 352; and private, 23,359. The quantity of gas sold shows an average increase of more than 7 per cent. The cost of coals per ton was 7d. more than in the previous year. The total amount of bad debts incurred and written off was only £433. The average price received for the coke shows an increase of 1s. 3d. per ton; while that for the tar shows an average decline of 6d. per ton, but this product is now being disposed of on better terms.

The Union des Gaz carry forward an undivided balance of £23,984, which, added to the special reserve account of £32,400, makes a total of £56,384 available, in case of need, for equalizing dividends in that Company.

Reverting to the affairs of the Continental Union Gas, the debenture debt of this Company stood in the balance sheet at £3100 on the 30th of June last; but the Directors are glad to be able to report that it has since been entirely paid off.

After making all the usual charges and reserves, the net profits of the Continental Union Company for the year amount to £116,867 1s. 5d.

The available sum to the credit of general revenue is £149,694 16s. 10d., out of which the Directors propose to declare a dividend at the rate of 13 per cent. per annum on the ordinary shares; being an increase of 1 per cent. on the previous year. The 7 per cent. preference shares participate *pro rata* in all ordinary dividends exceeding 10 per cent., and will therefore yield 10 per cent. for the year.

After deducting the interim dividend (paid in July last) of 5 per cent. on the ordinary and 3½ per cent. on the preference shares, the balance of 8 per cent. on the former and of 6½ per cent. on the latter, all free of income-tax, will be paid on the 1st of January next. The amount carried forward to the new account will be £35,159 0s. 10d.

The Directors are pleased to be thus justified in congratulating the shareholders on this prosperous state of affairs—a prosperity which they may reasonably hope to see maintained in the future.

The Congress of the Société Technique of foreign gas engineers having been held this year at Boulogne, The Gas Institute took the opportunity of inviting its members to extend their journey to London. The Directors of this Company had thus an opportunity of personal communication with their Managers, and availed themselves of it to the satisfaction of all concerned.

The Board regret to have to announce the loss of one of the original Directors of the Company—Mr. W. White—who died on the 21st of April last, and whose long and earnest services were highly appreciated by them. They have appointed Mr. Tendron (for many years an Auditor of the Company) to replace him.

The vacant auditorship has been filled up by the election of Mr. Eastman. The Director who retires by rotation is H. M'L. Backler, Esq., and the Auditors (Alfred Hersee, Esq., and A. T. Eastman, Esq.) also retire. All, being eligible, will be proposed for re-election.

The CHAIRMAN: Gentlemen, you have heard the report and accounts read; and you see how favourable they are. In commenting upon them, I will first of all take our own two stations—those stations which are our direct property—Messina and Montargis. You have seen how badly we were affected at Messina by the cholera—to such an extent that for a time it almost deprived us of our revenue. I am glad to say that this has entirely ceased; and we are now in a better position than we were before it took place, because the reduction in the price of gas which we consented to under the circumstances which I explained at the last meeting, has been productive of a great portion of the advantage which we expected from it, and which we shall ultimately secure. There can be no doubt of that. Now, I believe Messina will be a growing station—that is to say, it will bring a better revenue than it has done in the past; and for this reason, that the price of gas was really too high there. I thought so myself for some time; but the difficulty was how to give way without getting something in return. You will recollect that we did get something in return for the reduction in price, by obtaining from the Municipality an undertaking that all projects of electric lighting should be suppressed during a period of seven years; and I thought, during this period, we should take the opportunity of pushing the consumption of gas by reducing the price—the temptation being considerable to the consumers, who hitherto had been deprived of the use of gas by the high price at which we supplied it. Montargis has done fairly well during the year; we have no reason to complain of it. Having mentioned our own two stations, I will now pass on to make a few remarks on those of the Union des Gaz. The coal cost more than in the previous year; and for this cause: That the means of conveyance on the Italian railways are, at certain seasons of the year, so restricted, owing to the great traffic for which the railways are not yet fitted, that we experience considerable difficulty in getting coals from the ports at which the ships are discharged (almost entirely at Genoa) to the different stations we have in Italy—Milan, Parma, Modena, and Alessandria. Such, being the case, a certain number of waggons are allotted to the principal shippers of coal at Genoa; and we get our allotment in proportion to the accommodation which can be afforded. But it was not sufficient for our consumption, although we had laid in a large stock at Milan, which is the chief station to be supplied. In order to provide coal, at Milan principally, we were obliged to obtain a transfer of waggons allotted to the coal merchants who were sending coals to Milan, and who had these waggons allotted them as their proportion. We were obliged to buy the coals also which were loaded on the waggons. The consequence was that the coal merchants in Italy, who, like their brethren in England, do not do business for nothing, obliged us to pay them pretty well for the accommodation which they afforded us under these difficult circumstances. This is the reason why coals have been more expensive. Coal, as you are aware, is now rising in price; but I do not think we shall feel the effect of this very much, because we have coal contracts running over three years, and our freights are also secured for some time on favourable terms. Of course, when the contracts terminate, we shall have to run the chance of the markets, as

others must do. I am glad to say with regard to coke that we have reconquered the disadvantage under which we suffered with respect to coal; and we have, owing to the long winter which we passed through, and which seems likely to be repeated to some extent this season, managed to sell all our stocks everywhere, and at prices which are remunerative, and which enable us to annul the effect, as I said before, of the high prices of coal. Tar has recently improved in value; otherwise, during a portion of the year, it was not selling on such good terms as previously. I think we have now got over the difficulty, and shall be able to realize—we are, in fact, at this moment realizing—better prices than we did during the period with which we are making a comparison. The Milan concession, you observe by the report, has been modified to a considerable extent; and we have now got the contract extended to the year 1925. This is a very important advantage to us for a place like Milan; and we feel that it adds materially to the value of our interest in the Union des Gaz. The concessions, by the extension of this contract at Milan, have been raised in average length from 25 years—at which they stood last year, and from which, without this taking place, they would have been reduced to an average of 24 years—to 26 years; the longest being for 45 years. The gas-rental—I am still speaking of the Union des Gaz—has been increased by £16,522, or 4½ per cent. This is a very fair percentage; but the gas sold has been increased in a large ratio—that is, 7½ per cent.; and the reason why, while we have sold such a large excess in quantity of gas, we have received a smaller proportion in rental, is the various reductions of price to which we thought it wise to assent in the several towns, in order to conciliate our consumers, and to offer them the inducement to remain with us rather than go over to our competitor the electric light. We have succeeded as far as we expected to do in the matter. I will now pass on to our financial position with the Union des Gaz. You will recollect that we are holders of exactly 37,000 out of the 50,000 shares of that Company; and the market value of these shares has considerably improved since last year. We take the quotations of the Bourse of Paris, as recorded in the financial returns; and we find that the improvement is £58,000—that is to say, the market value of the shares we hold was last year £58,000 less than this year. This is the increased profit, or increment of value, of our holding in the Company; but you know we do not take that into account in our profits; this merely shows the stability of the Union des Gaz. If we were to add the increased market value of the shares this year, and the value were to fall, we should have to write it off the next; and we might perhaps pay you 20 per cent. this year, and be obliged to pay you only 14 or 15 per cent. (which I hope we shall some day be able to do) the next. We have the shares in our books at the price we paid for them—that is, the par value, £20 per share—representing a sum of £740,000. The market value of these shares represents a total sum of £1,908,000, at the present prices quoted on the Bourse; and consequently the investment we have in the Union des Gaz shows a total profit of £1,168,000, or £58,000 more than last year. (Applause.) That is very satisfactory to me, and so it appears to be to you, gentlemen. The stability of the Union des Gaz is also shown by the amount of their reserves. They have altogether reserves amounting to £378,514; and £35,990 has been taken out of the profits of the last year as an addition to the amount which stood to the credit of these reserves in the previous year. I think I may now take leave of our investment in the Union des Gaz for the present. You will clearly see what a satisfactory investment it is for us; and you will see whether or not we were justified in paying a considerable sum for the goodwill. The sum which we paid for that is now entirely extinguished. We have written it off in the course of years, little by little as our finances permitted; and although it is such a valuable property, it now stands in our books at par—that is *nil* for the extra commercial value of it. I will now revert to the Continental Union Gas Company, and just remark that, as you have heard in the report, the amount of the debentures has been entirely wiped off—we do not owe a farthing on debentures. The amount, which was originally £218,000, has been liquidated by small sums from year to year. There are few companies in this position—entirely free from debt of any kind. Now, the sum which we annually set aside for the writing off of these preliminary expenses having ceased during the past year, we were able to take into account the subject of increased dividend; and we are able to pay you an extra 1 per cent., which we now declare, owing to the cessation of this charge on our profits. The charge last year was something over £12,000; and we therefore declare this increase of 1 per cent., which will amount to £9272, and, in addition to that, we add to the undivided balance of profits £2331. This makes the undivided profits in the Continental Union Gas Company £35,159. If we did not leave a farthing over; if we had no reserve of undivided profit in this Company, we should still be in a first-rate position as to reserves, owing to the large one made by the Union des Gaz. However, we wish to be as prudent as we possibly can, in order to secure ourselves in every way; and therefore we have got this “nest-egg” of £35,159, which will enable us to keep up the dividends if it were necessary to do so at any time, or appropriate it for any other purposes we consider desirable. I will now merely refer to one or two matters which have occurred during the year. One is the visit of the Société Technique du Gaz to this country. only applicant for the post. I regard the position of the Company as excellent in every respect. You see we have an improved security in the Union des Gaz; and we have likewise improved our position in the Continental Union Gas Company. We have secured to the Union des Gaz the extension of the Milan concession; and have reason to believe that we shall, little by little, as circumstances permit, also obtain extensions elsewhere where the contracts are of short duration. I may safely congratulate you on the investment which you hold in this Company. I am sure it is a good one. I feel it is a good one so far as my portion is concerned; and what I feel for myself, I am able to apply to you all. I will now move—"That the report of the Directors and the accounts now read be received and adopted."

Mr. H. WOLLASTON BLAKE seconded the motion, which was at once carried unanimously.

Mr. BLAKE then proposed the re-election of Mr. H. M'L. Backler, who retired from the Board by rotation. In doing so, he observed that the shareholders owed very much indeed to Mr. Backler for the success of the Company.

Mr. H. SOLOMON seconded the proposal, which was heartily confirmed by the shareholders.

The CHAIRMAN having acknowledged his re-election in a few appropriate words,

On the motion of Mr. R. G. COOPER, seconded by Mr. A. HOWARD, the retiring Auditors (Messrs. Hersee and Eastman) were re-instated.

Mr. A. LUCAS, in proposing a vote of thanks to the Secretary, Engineers, and staff generally, referred to the visit which he paid some time since to the stations of the Company, and remarked upon the excellent order in which they were kept, and the great ability shown by those who had the supervision of the technical departments. The Engineers not only had to look after the works, but had also to act as agents to push the business, and had often to conduct complicated negotiations like those they had lately had at Milan.

Mr. TENDRON seconded the proposition. The Chairman, he said, had asked him to narrate the impressions he received during his visit in October last to the French stations of the Company. His impressions were eminently favourable. Four of the cities—Rueil, Roanne, Nîmes, and Cette—were, he thought, capable of great development. Their extension would not depend upon any effort of the Company, but from the nature of things the cities must extend. As to the competition which they might expect to meet from the electric light, it seemed to him that the French were not only the most economical nation in many things, but they were especially so in the use of light; and anything that would educate them into a keener appreciation of the immense advantages that a good light will bring, would be to the Company's benefit. In some of the cities, the only really well-lighted shops were the cafés and restaurants; and in many of the streets of the smaller towns, gas is not used at all—petroleum being the illuminant. In only one of the cities which they supplied had there been more than a commencement of the electric light. In conclusion, he said that the Company had by no means reached its maximum prosperity.

The motion was carried *nem. con.*

The SECRETARY having acknowledged the compliment,

Colonel WILKINSON moved a vote of thanks to the Chairman and Directors; speaking in high terms of the admirable manner in which the affairs of the Company were conducted.

Mr. COOPER seconded the motion.

The CHAIRMAN briefly responded; and the proceedings then terminated.

SOUTHWARK AND VAUXHALL WATER COMPANY.

The Half-Yearly General Meeting of this Company was held last Tuesday, at the Offices, Sumner Street, Southwark—Alderman Sir H. E. KNIGHT in the chair.

The SECRETARY (Mr. Alfred Jelley) read the notice calling the meeting, and afterwards, at the request of the chairman, the minutes of the ordinary meeting held on the 12th of June and of the extraordinary meeting held on the 30th of October last. These minutes having been approved by the meeting as correctly entered, the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: I shall detain you but a very few moments to-day. I have little to tell you different from what I had the pleasure of telling you at the last meeting, and I think you may judge from that that we are going on prosperously and well, because generally when a Chairman has not much to say things are progressing satisfactorily. I will follow my usual custom on these occasions, and go through the accounts. You see that we have over-spent our capital account by £79,900; and that will show you that the £100,000 of debenture stock which we have issued was absolutely wanted to make good those payments and to leave us with a little surplus. That stock is to be applied for by tender, and the tenders are to be received, I think, next Monday. I have very little doubt that we shall issue that stock at a very satisfactory price. In dealing with our revenue account you will notice that under the head of maintenance, we have an amount of £14,000, as against £11,000, this time last year, showing a large difference; but I may tell you that this £3000 is an exceptional expenditure mostly made up by money that we have spent in erecting hydrants for the Metropolitan Board of Works, and which they have not yet paid us for, and the credit for which is therefore not brought into account. I should next like to call attention to the item of rates and taxes, amounting in the present accounts to £8400, against £7600 in the preceding year. I have frequently called your attention to the continual and enormous increase in the rates and taxes which we have to pay. The total expenditure under the head of maintenance is £39,000, as against £36,000 this time last year. There are certain savings in some of the other items which bring the increase to only about £3000. Thus, you will find that the amount we have for dividend and interest is £55,801. This is a very good increase on last half year, when the amount was about £53,000, so that we have now an increase of nearly £3000. But the item is less than it was at September, 1887, by some £3600, which is mainly accounted for by the items to which I have already called your attention—the charge for hydrants erected for the Metropolitan Board of Works, and the large increase in our rates and taxes. On the other side, the item of water rents accrued is a satisfactory one to refer to as the amount this year is £106,874, against £100,600 in March last, showing a very handsome increase indeed for the half year. But when I compare it with that of September, 1887, I find only the small increase of £200. This is accounted for because in September last year we had a wonderfully good meter account. It was a very dry summer that year and we received a large amount for road watering and a very large amount for meter-rental, whereas this summer it was wet and we had a very large falling off in the amount received for road watering and meter rental. Still, it is a good increase in the half year, and you will notice that we have not taken into account the money due from the Metropolitan Board of Works for the hydrants we have fixed for them. This item stands now at the largest amount we have ever had since September, 1884, when the water rents accrued stood at £108,411, so that within about

£1500 we have recovered the loss which we sustained in consequence of the alteration made in the basis on which the water rents were charged. Bringing this £55,000 into the account and deducting from it the dividend which has to be paid on the preference stock and so on, we have a balance of £38,305 applicable to dividend. As it will take £30,861 to pay you a dividend of 6 per cent. we shall carry forward £7440 or something like £1500 more than we carried forward last half year, showing that we are making substantial progress in getting a nice surplus in hand. Now, I really do not know that there are any other items to which I need refer. There is the temporary loan of £66,000; but if we have over-spent our capital by £79,000, we must have money from somewhere. This temporary loan, however, will now be paid off when we get out our debenture stock. It has been a financial operation of a very delicate nature, which I think we have carried out very successfully, managing the matter very much to the financial benefit of the Company. We cannot issue these debentures in small sums; they must be issued in respectable amounts, and we must avail ourselves of our credit to carry us through until the time when we allot them. With respect to the report that is before you—and I do not know that I can enlarge upon it—we have mentioned the salient features in connection with our working. I can only say as regards the gentlemen who retire, that we should be very sorry to lose them as colleagues, and I think you would not do well to lose them as Directors. They know your business well, and I have no doubt that when the proper time for proposing their re-election arrives you will duly re-appoint them. As to the question of Auditors, we were very sorry to lose the services of Mr. Young who had been Auditor for a long while. He was removed, however, as you know, by death; and we have had to look about for another gentleman to take his place. We recommend to you with great confidence Mr. Child, who is mentioned in the report. We have availed ourselves of his services in the present half year. That is an appointment, however, which rests with you; but we recommend this gentleman, believing that he will serve you properly. I had hoped that we should have seen you this half year in our new offices round the corner; but there was some delay in connection with the warming and the lighting which we did not anticipate, and we thought it wiser to stay here a few weeks longer and get everything completed at the new offices. Some of you have seen the building, which will give us every facility for conducting the business of the Company. It is an excellent investment, and none of the cost will be borne by the proprietors—the premium on the investments being a great deal more than the cost of the land and the buildings—and we shall be able to do our business well without any fear of our clerks falling ill in consequence of the wretched accommodation to which they have to submit here. We think the building will last us a great many years as it is, and there is room for an increase of accommodation in it in the future; and I have no doubt when you see it completed you will again express your great satisfaction with it as you have done already in its incomplete state. I believe you will say that for a Company with a capital of £2,000,000 we have now provided respectable offices. With regard to the well at Streatham, that is a question which has been a most interesting one for a great many years. Supported by you at every meeting, we have persevered with that work in the hope that we should tap the great supply of water which geologists told us lay under this London of ours. We went on until we got down to a depth of 1239 feet; and we were then on sandstone rock. The Geologists told us the samples brought up could not tell us whether it was the old red sandstone or not; and advised us to continue boring, and we did so to the depth I have mentioned. We then came to the conclusion from the samples obtained, and from the opinion of the Geologists, that there was no hope of obtaining water; and we considered that our duty in connection with the matter was at an end. We were boring for water and sinking for water, and when we came to the conclusion that it was not to be found we did not feel justified in spending another penny. We therefore ceased boring; but I may tell you that the contractors in a very spirited manner continued the boring at their own expense, and they got down to 1271 feet. They at this greater depth to which they went came across a fossil. That fossil has been submitted to the geologists, who, I believe, say that there is no doubt that it is a fossil on the old red sandstone, which confirms the belief which we have that there is no use in seeking for the water any farther. It is a very interesting business; but taken in conjunction with the fact that at Richmond they went down 1446 feet and found nothing but sandstone, and that at Meux's brewery they went down to 1146 feet and found no water, I think we may take it for granted that the theory which existed that there was an unlimited supply of water under London for its supply is exploded. We have proved now by these three borings (and there have been others) this fact indisputably; and it is of no use people thinking that they can be supplied by water that is under London. They must be supplied therefore from a distance or else from the source placed at their disposal by Providence in the River Thames. It is therefore more than ever necessary to keep the Thames pure and wholesome; for it is an infinitely better source than can be found in any well for domestic purposes. Before I sit down, I must bear testimony to the good conduct of your staff, all of whom are working well. I have spoken of the Engineer before; and I mention him now to say that we are greatly indebted to him for his advice and assistance in all our undertakings. The magnificent engines he recently put up at Hampton are saving you greatly in the consumption of fuel, and the pumping is done infinitely better. Our Secretary and the other members of our staff are also looking well after your interests; and I may say that our work is now done much better than it was a few years ago—I think indeed that it is now done far better than ever it was before. With these remarks, and again expressing my readiness, as on previous occasions, to answer any questions that may be put to me, I beg to move "That the report and accounts of the Directors submitted to this meeting be and the same are hereby received and adopted."

Mr. CHARLES MARSH VIALLS seconded the motion.

In reply to Mr. Bradford,

The CHAIRMAN said that, speaking from memory, he did not think they had power to compel the consumers to have cisterns with the constant supply; but any man who was discreet would not rely entirely on the constant supply and do away with his cistern. The cistern required to be cleaned out every 3 or 6 months, and if that were done the consumers could not have a better water supply.

Mr. FRENCH asked questions with reference to the commission paid to the Engineer and other items in the accounts.

Mr. WASHINGTON asked where they expected to get water from as they had failed in their efforts at Streatham; and afterwards inquired the loss the Company estimated they sustained by boring for water which they did not obtain. He thought the provision for bad debts was heavy.

Mr. GREEN spoke of the steady increase in the last nine years in the item of maintenance, which had risen from £5691 to the extraordinary amount which now figured in the accounts. He had no doubt, however, that sufficient reasons could be given for this increase in the charges. He thought the law and parliamentary charges for the last half year (£584) were heavy, because he had imagined that their parliamentary difficulties were over. He afterwards expressed extreme satisfaction at the steady

and continual decline in the item of allowances for overcharges. In 1885 that item stood at no less than £7228 from which point it had decreased by leaps and bounds, figuring in the present accounts for under £1000. This reduction in the item seemed to him to indicate that the shareholders and the ratepayers were working more in harmony and that much pleasanter feelings seemed likely to exist. In looking back for the last nine years he found that only on one occasion had the item in question been less, viz. in 1882, when it was £723. He hoped and felt sure that the Directors would continue to reduce the item even still further in the future.

After a few observations from Mr. JONES,

The CHAIRMAN, in further reply, stated that their former Engineer, Mr. Rumball, received a large salary—£1700 or £1500 a year, all of which was a charge against the revenue. That system was a wrong one. For instance, part of the cost of a building was architect's commission, and part of the cost of erecting an engine was engineer's commission. They paid to the present Engineer a salary of £750, and to a gentleman outside their staff they would have to pay on calling in his services full commission. They paid not the full commission which they would have to pay to outside people, but a commuted commission—something like one-half, or in some cases one-third, of the full commission. Therefore the proprietors got their work done by a man who was perfectly well acquainted with their affairs, and could look after the work thoroughly. Mr. Restler was exceedingly competent to advise the Board in every way as to the building. In regard to Mr. Washington's question, they had only failed to find water at the deep borings at Streatham. In the upper sand above the chalk they had met with a large supply of water—some few million gallons a day—and they were thus amply repaid for the outlay there. They had an abundant supply for their district; and when the new main was laid from Hampton they would have an ample supply of water for 10 or 15 years. If the well at Streatham had turned out what they expected, and had given them a large supply of water from the lower green sand, they would not have had to lay a new main from Hampton, and then they would have saved £70,000. It was therefore worth some risk to see if such a large outlay could be avoided. They always depended on their supply from the Thames; and having failed in tapping a large supply at a reasonable depth at the well at Streatham, they were now in much the same position as before they undertook to sink the well. He had explained that the item of £14,094 for maintenance included an exceptional amount of £3000 which would appear on another occasion in their revenue account. The lower figures to which Mr. Green had referred under the head of maintenance were the charges which prevailed before the Company began giving the constant supply. In the past year alone 18,000 houses in their district had been put on constant supply. They had had very few parliamentary expenses; but they had had to incur some outlay in watching Bills in Parliament and in arranging clauses for the protection of the Company's interests. A considerable part of the item of law and parliamentary charges was in connection with one or two claims which had been made against them for accidents arising in the progress of their works, and which they had thought it more advisable to settle. As regarded the reduction of the overcharges, there was no doubt that that was a very gratifying feature in their accounts; but it had to be remembered that the large sums mentioned came just after the Torrens Bill was passed. With reference to Mr. Jones's question, the total amount received for water-rents was so much, and he was afraid that Mr. Jones was confusing that amount with the amount of the charges which included the old houses, debts, &c. In connection with this item also, a difficulty arose in the book-keeping owing to the way in which the rents were collected from one quarter to another, the accounts being made out for the other two quarters. The Company would incur no loss at all in having sunk the well at Streatham, because the quantity of water which they had obtained from the chalk and above the chalk would make the outlay a good investment. The provision of £8000 for bad debts they had to make at the request of the Government Auditor; but the amount was to meet the contingent loss they might have in connection with empty houses, overcharges, and bad debts.

The motion was carried unanimously.

The CHAIRMAN proposed the following resolution: "That the following half-yearly dividends be declared after the 15th day of January, 1889, viz. :—at the rate of 45 per cent. per annum on the preference stock, and 46 per cent. per annum on the ordinary stock and the class "D" shares of the Company."

Mr. VIALLS seconded the resolution which was carried unanimously.

On the motion of Mr. BRADFIELD, the retiring Directors (Mr. Henry Whiting, Mr. C. M. Vialls, and Mr. E. Ponsonby) were re-elected.

And subsequently also on the motion of Mr. BRADFIELD, Mr. Trayton Pagden Child, C.A., was elected Auditor to fill the vacancy caused by the death of Mr. Young.

Votes of thanks were passed to the Chairman and Directors; and to the Secretary, Engineer, and staff after which the proceedings terminated.

GRAND JUNCTION WATER-WORKS COMPANY.

The Half-Yearly General Assembly of this Company was held last Wednesday, at the Offices, No. 65, South Molton Street—Mr. E. G. Fox in the chair.

The ACTING SECRETARY (Mr. J. W. Fisher) read the notice convening the meeting; and it was agreed to take as read the report of the Directors and the statement of accounts for the half year ended Sept. 30. The report was referred to in the JOURNAL for the 4th inst., p. 996; and from the revenue account we learn that the total receipts for the six months, including £6500 brought forward, amounted to £92,532, and the expenditure to £31,798. The sum carried to dividend account was £54,233; leaving £6500 to be carried to the next account, to provide for losses.

The CHAIRMAN: I have but few remarks to make to you on this occasion. We are in a very happy state. I do not think there is any point to which I need refer in the accounts, except that we find our water-rental has been less by some £1260, in consequence of the wet weather during the half year. But for this, there would have been an increase in the item. As to maintenance and management charges, there is a little excess; but we are now increasing by 1100 or 1200 every year the number of houses that we supply. It is therefore necessary that we should have more power; so that you cannot expect always to see these items less. With regard to rates and taxes, there has been an increase; but whatever may be the position of the accounts, they have passed through the hands of the Government Auditor, and he is perfectly satisfied. From the report, you will gather that last year the weather was very dry; and therefore a great deal of water was wanted, and we had the benefit of that. In the past summer, however, the season was very wet, so that we were minus in our receipts by about £1260. We are happy to say that, on the whole, we have an increase in our undivided balance, after paying the dividend, of about £300. We shall have £3900 left after paying the dividend of 9 per cent.; so that we are not going back. With respect to our works and pumping station and the quality of the water

we have supplied, we stand exceedingly well; and as to the latter point, our report shows that we stand better than some of the other companies, as far as the clearness and brightness of the water are concerned. We have opened our large reservoir at Ealing; and looking at the interests of the shareholders, we decided on having a little ceremony on the occasion, so we invited a number of people connected with the locality—such as the members of the Local Board, and the members of Parliament for the district—and the event was most successful. All who were present felt that they were allowed to look on a work such as they had never seen; and one Medical Officer who was among the company, took me on one side, and said: "I am delighted that you have given us the opportunity of seeing these works. I had no idea that the water companies took so much care in regard to the water they supply." Well we had a great number of friends amongst us on that occasion; and we enlightened many people who wished to know something about water-works. The subject had been a sealed book to them before. There is only 10 feet of water in the reservoir at present. We intend to fill it by degrees, so as to keep the pressure gradually on before regularly using the reservoir. Last year the number of houses we supply increased by 1074; and in consequence of the continuous increase, and the rapid growth of the district, more especially between Acton and Sunbury, we felt obliged to have more power, and we have ordered a new pumping-engine, and three boilers, to be erected at Hampton. This work is now proceeding; and I hope it will be finished next year. We found in the dry summer we had last year that a great strain was put upon us. However, we got over all our difficulties; and therefore I will say no more about it. But it would not do to let such a dry summer come upon us again, without being prepared to meet it by improved resources; and so we took the precaution of ordering this new pumping-engine and additional boilers. In his last return, the Water Examiner stated that we have 42,483 houses supplied on the constant system, as compared with 41,772 in the previous return. Then I must call your attention to another matter. Our friend Mr. Coe took leave of us on Sept. 29, after spending 57 years in the Company's service. The work done by that gentleman has been alluded to more than once at our meetings; but one can always say something kind of a man who served the Company so well. He was for 34 years our Secretary. I mention this now, because the resolution which you passed on a former occasion voting him an annual sum as a retiring pension in recognition of his services is now to come into force. We feel it our duty to mention this to you to-day. I have now to move—"That the report of the Directors and the statement of accounts be approved and confirmed, and that the recommendations contained therein be adopted."

Mr. H. MOTT seconded the motion, which was carried unanimously.

On the motion of Mr. F. TAGART, seconded by Mr. C. J. B. HERTSFLET, the following resolution was also unanimously agreed to:—"That a dividend for the last financial half year at the rate of 9 per cent. per annum upon the ordinary share capital of the Company and of 7½ per cent. per annum on the £25 "C" shares, and of 7 per cent. per annum on the new ordinary £50 shares, together with interest in accordance with the conditions of sale on payments on the shares issued in February, 1883, be now declared, and that warrants be issued for payment of the same on and after the 15th of January next."

Mr. W. HUNTER moved, and Mr. GIVENS seconded, a vote of thanks to the Chairman and Directors for their admirable conduct of the business of the Company during the half year.

The CHAIRMAN briefly acknowledged the compliment, and the proceedings terminated.

CHELSEA WATER-WORKS COMPANY.

The Half-Yearly General Meeting of this Company was held last Thursday, at the Offices, Commercial Road, Pimlico—Sir W. H. WYATT in the chair.

The SECRETARY (Mr. G. H. Gill) read the notice convening the meeting; and the report of the Directors and statement of accounts for the half year ending Sept. 30 were taken as read. The gross income in the six months amounted to £65,914; and the working expenses to £19,736. The capital account showed an expenditure of £2144, which included the final payment to the contractors in respect of the new Worthington engine at the Molesley works, the cost of the erection of a stand-pipe at the Putney Heath reservoirs, and the expenditure on ordinary extensions in the district. The quantity of water pumped into the service reservoirs during the half year was 1755 million gallons.

The GOVERNOR: Gentlemen,—In rising to move the adoption of the report, I must say I have very little to add to what has been circulated among you. I would first call your attention to the fact that our income for the half year has been £65,900; and the expenses have been £19,700. This you may take to be a very satisfactory state of things; and it will certainly compare favourably with any other water company. When you can get your expenses to a point not exceeding 30 per cent. of your revenue, you can feel quite satisfied that there is not much to complain of. You may find that some other companies do quite as well (I am not sure that many of them do), but none of them do better. If you can get 70 per cent. of your receipts paid as dividend, it must be a matter of satisfaction. The only way to do this is, of course, to watch very closely the expenditure, as we do. You will see that we have paid a certain amount to the contractor for the Worthington engine during the past half year; and I am glad to tell you that this engine is doing its work exceedingly well, and will result in very considerable profit to you, so far as the consumption of coal is concerned—that is to say, it will do a much larger duty per ton than the others did. The quantity of water pumped in the half year has been less than that in the corresponding period of 1887. But the summer of that year was very dry; and this summer has been wet, which has made a considerable difference. The next point I would call your attention to is with respect to the demolition of old houses in Chelsea and Brompton. I forget how many were pulled down; but I believe there were more than 1000; and we thought this half year we should find our rental very considerably diminished. I am glad to say that this has not been the case, for rebuilding has gone on very quickly; and the houses that are being put up are of a different character, and will yield a much better income, though probably they may use more water. The Directors are, therefore, particularly pleased with the income for the year, because it enables us to pay the full dividend of 9 per cent., with a slight surplus over, though not much. This is a better result than we had anticipated. We were afraid this half year that we might have had to draw on our reserves to make up the 9 per cent. We are exceedingly gratified that we have not had to do so. I ought to say—and it is only fair that I should say it—that a great deal of the saving in expense is due to the great attention and care given to the working of the engines. Under our present Engineer, the old engines have been almost entirely recast. The result is that they do a much better duty, and they do not consume anything like the quantity of coal which they did previously. This is owing entirely to the care and ability which the Engineer has shown in bringing this about. It is, of course, important for us if we can save a thousand pounds in coal. The quality

of the water that we have supplied has been good. I do not think it was ever better; showing the great care that has been paid to the filtration. There has not been a single complaint, I believe, as to the quality of the water from any of the consumers during the year—a fact which I think shows a satisfactory state of things; and, moreover, no fault has been found by those who have to examine the water. We have had to raise, as you are aware, a small amount of capital. We keep the capital down as much as possible, because the more capital you have to pay dividend on, the less there is for everyone. Therefore, we have kept it as low as possible. We have obtained a quotation in the past half year for the Company's preference and debenture stocks. I believe that this has added to the welfare of the proprietors; inasmuch as it may have improved, by 1 or 2 per cent., the selling value for anyone who wishes to dispose of his stock, though, of course, the quotation has not added to their real value. I have now to move the adoption of the report and accounts.

The DEPUTY-GOVERNOR (Mr. F. S. Clayton) seconded the motion, which was carried unanimously.

On the motion of the GOVERNOR, seconded by the DEPUTY-GOVERNOR, resolutions were afterwards passed authorizing the Directors to provide for the payment of the preference dividend, and declaring a dividend for the past half year at the rate of 9 per cent., per annum.

Mr. WARD proposed a vote of thanks to the Governor and the Court of Directors for their careful management of the Company's affairs in the past half year, speaking in terms of great satisfaction of the position of the Company and the steady progress it is making towards the payment of the maximum dividend of 10 per cent.

The resolution was seconded, and carried unanimously.

The GOVERNOR, in acknowledging the compliment, assured the proprietors that with the aid of a most excellent staff, the Directors did everything in their power to promote the interests of the Company.

The proceedings then terminated.

THE PUBLIC LIGHTING OF DUBLIN.

At the Meeting of the Dublin Municipal Council on the 10th inst., the question of the public lighting of the city was again under discussion.

Mr. DENNEHY called attention to "the number of serious complaints of the citizens with reference to the present defective lighting of the city, and to the serious liability that will result to the Corporation in case any accident should occur therefrom." He moved—"That this matter be referred to the Paving and Lighting Committee, with a request that they will report to the Council on the subject."

Mr. DOHERTY seconded the motion.

Mr. MAYNE observed that he was a member of the Gas Sub-Committee who were at present considering the question. They found the lighting of the city was bad; and they called the attention of their Gas Inspector to it. The gas-testing arrangements on which they were accustomed to rely were more or less of a sham. The testing station at Burgh Quay was in a room next to a garret; but as all the gas-pipes of the city did not happen to pass Burgh Quay, it was impossible to test the gas supplied to the bulk of the consumers. The gas supplied to the south of the city did not appear to be tested at all. Their officer suggested that the gas-testing apparatus in Hanover Street, which had not been used for a great many years, should be put in order, and the latest improvements added to it. This was done; and the result was very strange. The gas tested at Hanover Street was not of 16-candle power; and in many instances was not 14-candle gas.

Alderman DILLON: What about Dr. Tichborne's test?

Mr. MAYNE replied that Dr. Tichborne must answer for himself. He tested the gas at Burgh Quay and his own house at the north side of the city. The main that passed Burgh Quay was the great north main; but there was a peculiarity about Burgh Quay, that, until very recently, it was absolutely impossible to make a proper test there, for the instruments were defective. The Committee suggested Tara Street as a suitable place for testing. They would there have the command of all the principal mains except one. With all the anxiety of the Gas Company to help to do what was right and proper, yet, although it was three months since the Committee made this suggestion—in fact, made the demand—yet from that time to the present they had never obtained any satisfactory answer from them. The Committee had thought it well to call in an expert to make an independent series of testings, which corroborated their own Inspector to a fraction, both with regard to quality and purity. As soon as the Lord Mayor returned to Dublin, they would resume their representations to the Gas Company; and if they continued unsuccessful they would have to ask the Corporation to take legal steps to insist on the Gas Company putting the testing station where it ought to be—that was, where the largest number of mains could be tested.

Alderman MULLIGAN said the Committee had frequently had to call upon the Gas Company to keep the lighting plant in order. The lamps of Dublin were falling asunder for want of care. He found from the report of their Inspector that on Oct. 25, the quality of the gas was 13·8 candles; on the 26th, 14·50; on the 27th, 15·80; on the 29th, 15·50; on the 30th, 14·70; on the 31st, 13·90; on Nov. 1, 14·10; and on the 2nd ult., 13·60 candles.

Mr. GILL asked Alderman Mulligan, to read Dr. Tichborne's report.

Alderman MULLIGAN replied that he had not got it. Continuing, he said that the quality of the gas on Nov. 28 was 14·4 candles; on the 29th, 15·5; and on the 30th, 15·2. Mr. Cotton mentioned to him that on Saturday last the quality of the gas was 13·8 candles. These were testings taken at the official station.

Mr. GILL said that Mr. Mayne and Alderman Mulligan had made observations from two different standpoints. Mr. Mayne stated that Mr. Cotton's testing took place in a different place from Dr. Tichborne's, and that it might be accounted for by assuming that different gas was sent through the mains to Mr. Cotton from what was sent to Professor Tichborne.

Mr. MAYNE: I did not say so.

Mr. GILL observed that it might be accounted for in that way. He hoped that Dr. Tichborne would answer for himself, because both Mr. Mayne and Alderman Mulligan, by implication, had accused him of assisting the Gas Company to cheat the public (No. no). Dr. Tichborne tested the gas; and every week stated that it was up to a certain standpoint. Mr. Cotton tested the gas; and according to Alderman Mulligan and Mr. Mayne, he made it more than 2 candles less than an experienced tester like Dr. Tichborne. Had Alderman Mulligan or Mr. Mayne proof that Mr. Cotton ever tested a single jet of gas up to the time that he was employed by the Corporation? Then they brought over someone to back up his testing; it might be a friend of his, or somebody that knew no more about testing than he did himself. The whole tendency of the present dispute was almost, in set words, to accuse Dr. Tichborne of helping the Gas Company to cheat the public.

Mr. MAYNE thought he was justified in saying that if Mr. Gill could make a case for his Company in opposition to the strong one that he (Mr. Mayne) had made, let him do so. He did not know what Dr. Tichborne was doing with the gas; whether he was testing it or not. If he was testing

it, and gave in a report about his testing he (Mr. Mayne) would believe it. He was aware that Dr. Tichborne made his testing late in the evening; and everybody was aware that the bulk of the consumption of gas was over before six o'clock, when Dr. Tichborne made his test. There might be, and had been, in previous years a very bad quality of gas in the mains while the consumption was large; and a good quality in the mains at seven or eight o'clock in the evening.

Mr. M'QUAID said if the Corporation had allowed the state of things to go on that was described by Alderman Mulligan, it was a disgrace. A gentleman who made a contract and acted as the Company had done would be scouted out of public life.

Alderman DILLON remarked that he could well understand Mr. M'Quaid's indignation; but he did not think he ought to blame the present officers or Committee. This state of things had been going on in the city for several years. The relations between the Corporation and the Gas Company were only changed a few months ago. He thought every latitude ought to be given to the present Inspectors of the Gas Committee. It would have been better if this discussion had not taken place until they had an independent report in writing from the Committee. He was disposed to think a condition of things would be found to exist which justified all the accusations made by the officers of the Corporation last year, and all the suggestions made for many years past as to the unsatisfactory relations between the Gas Company and the Corporation; and he would be very much surprised if he did not find Mr. Gill coming forward like an honourable man, and saying that he had been deceived, and that he had discovered that the relations between the Company and the Corporation were such as should not be allowed to exist. He begged of the Committee not to disclose their hand to the Company until the time came for doing so.

Mr. M'QUAID remarked that he did not intend to convey any reflection on the Sub-Committee.

Mr. DOHERTY said he would like to know if any communication had passed between the Paving and Lighting Committee and Professor Tichborne. He hoped it would be conveyed to the Gas Company by their friends in the Corporation that there were penalties hanging over them if they did not supply the city with proper light.

Mr. CUMMINS said it was a disgrace that two bodies like the Corporation and the Gas Company could not come to some honourable understanding on the subject. Mr. Cotton, their Gas Inspector, had done good and efficient service since his appointment; and the testing by an independent expert bore out the view of his capacity taken by those who elected him.

Mr. DENNEHY observed that he did not think the Gas Company or their Secretary would deliberately commit such a fraud as to supply gas so inferior to what they were bound to afford. But it was obvious that the subject was one of vast interest, and deserved the most careful consideration.

The CHAIRMAN, referring to an observation made by Mr. M'Quaid, said he wished to give one word of explanation. He, as a member of the Council, felt that he would be seriously liable if he allowed a state of things such as that described to go on without drawing instant attention to it. But it should not be understood that there had hitherto been any discrepancies between Professor Tichborne's reports and those of their officers. Before Mr. Cotton's appointment, they had an Inspector who came to them with a return agreeing with Professor Tichborne. Now, under the new state of things, they were presented with returns differing from Professor Tichborne; and they at once took action, so that they were free from any blame in the matter.

Mr. M'QUAID said he did not wish to be misunderstood. He only meant to convey his opinion that a course of conduct should not be tolerated by the Corporation which would not be permitted by private individuals; and he never intended for a moment to reflect upon, or act as censor on the gentlemen who were in the Council before he became a member.

The motion was then carried.

Mr. W. F. Cotton, Secretary and General Manager of the Alliance and Dublin Consumers' Gas Company, has addressed a letter to the Corporation of Dublin, under date of the 13th inst., in the course of which—alluding to the debate reported above—he says: "My Board have directed me to state that for some time past reckless and unfounded charges and insinuations have been made affecting the honesty of this Company, and which, if true, would show that the Company, with the knowledge of the Board and their Manager, have been defrauding the public for many years. These charges have been made under the shelter of the privilege which the position the members hold in the Corporation affords them, and when challenged are met by vague evasions, but only to be repeated again and again, until the public are led to believe that there must be some foundation in fact for the statements so often made. In the debate, however, on the 10th inst., a definite charge has been made which should be dealt with at once—viz., that on the following dates, Oct. 25, 26, 27, 29, 30, 31, Nov. 1, 2, 28, 29, 30, and Dec. 8, the gas supplied by the Company was under the standard fixed by Parliament. This statement, apparently, has been made on the authority of your Inspector of Public Lighting, corroborated by some person whose name is not given to the public. These charges have, if true, involved the Company in liability to penalties of £20 for each occasion, amounting to £240, payable to the Corporation; and this sum can be recovered before the Divisional Magistrates of the city. My Board respectfully demand that the Corporation should test the correctness of their charges; and, in fairness to the citizens, and in justice to the Company, direct that proceedings be at once taken to enforce these penalties. If the above challenge is declined, my Board can only conclude that the members of your Committee, while giving publicity to charges made by your Inspector, which may injuriously affect the Company, have no confidence in their correctness."

In alluding to the above letter, the *Freeman's Journal* characterizes it as "the not unnatural outcome of the last meeting of the Corporation. The dispute between the Gas Company and the City Council is no longer a matter of vague allegation or suggestion; it is a definite accusation. The Company are charged with having supplied the city with gas which is under the standard fixed by Parliament, and twelve dates are specified as those upon which the insufficient supply was detected. . . . While we think the Corporation have, to some extent, exhibited an exceedingly bad spirit in the discussion of this question, and have gone the worst way to effect a settlement, we do not expect that they will feel compelled to accept Mr. Cotton's challenge. In the matter of legal proceedings, the Corporation need not go beyond its own excellent Law Agent. Nor is it, in our opinion, a matter for litigation at all. Doctors differ, and so may inspectors of public lighting; and, as we have said again and again, half-a-dozen level-headed, practical men, who honestly wanted to settle the matter, could find a basis for friendly agreement in two days. Such a squabble as has been carried on so long between the Corporation and the Gas Company is creditable to neither party."

The stokers in the employ of the Wolverhampton Gas Company have had their wages advanced by 2s. a week.

ROCHDALE CORPORATION GAS-WORKS.

A REDUCTION IN PRICE.

On Thursday, the 6th inst., at the Meeting of the Rochdale Town Council—the Mayor (Mr. J. E. Petrie) in the chair—the Gas Committee presented a resolution recommending the Council to reduce the price of gas within the borough from 3s. 2d. to 2s. 11d. per 1000 cubic feet, with discounts as before; such reduction to commence as and from the next quarterly inspection of meters.

Alderman PETRIE moved the adoption of the resolution. He said the reason the Committee moved in the matter was not because their circumstances had changed in any way; but rather in fulfilment of the understanding which was tacitly arrived at when the last reduction was made. That was now nine months ago, at the beginning of the financial year. It was then felt that 3d. per 1000 feet was not the full amount by which they were warranted in reducing the price; but it was deemed prudent to "come downstairs" gradually, three steps at a time, rather than jump down the whole flight at once. As to the estimated effect of the 3d. per 1000 feet reduction, it would be about £3300 for the year. That was the lessening of the revenue consequent on the last reduction, which took effect throughout the whole financial year. The present reduction would take effect after the end of this month; and it would mean little or no alteration of the revenue for the current year, because the new contract price of coal, and the normal increase in the consumption of gas, would about make up for the lessened receipts. Irrespective of this, however, his feeling was that it was quite time that gas was made, like other things, cheap. It was about the only thing in the town that remained dear at the present time. Looking at the great advance in the improvement of other modes of lighting, and the consequent serious competition, he thought the Council would be justified in feeling that it was high time they adopted this resolution. He only hoped they had not delayed too long before taking the step.

Alderman BARON seconded the motion. He said he was glad the reduction was made at twice instead of at once; and he hoped it would be the last they would have for some years to come. An article was cheap or dear according to comparison; and he did not think that Rochdale gas was very dear. The net price when this reduction was made would be 2s. 7d. or 2s. 7½d. In Accrington the net price was 3s. 1d.; Barrow, 3s. 6d.; Blackburn, 2s. 9½d.; Brighton, 3s. 1d.; Chester, 3s. 4d.; Coventry, 3s.; Dewsbury, 3s.; Huddersfield, 2s. 7½d.; Macclesfield, 3s.; Norwich, 3s. 4d.; Southport, 2s. 10½d.; Swansea, 2s. 10d.; St. Helens, 2s. 10d.; Preston, 2s. 9d.; Wigan, 2s. 9½d.; and Manchester, 2s. 8d. (A VOICE: Bury.) He had painted one picture; if they wanted another, let them paint it themselves. (Laughter.) There were as important places in that list as any that could be brought against them; and there was no borough in the kingdom situated like Rochdale with reference to one department (water). They were a trading community so far as gas and water were concerned; and he hoped it would be a long time before they again reduced the price of gas while they were supplying water to thousands of householders in Rochdale at considerably less than cost price. Thousands of people were having water at about 7d., 8d., or 9d. per 1000 gallons, while it cost him 3s. or 4s. But while they were having water at less than cost price, it was now proposed to let them have gas at less than cost price, too. ("No.") Certainly it was so. Taking the receipts for gas in hundreds of houses, that commodity was supplied at an absolute loss.

Alderman PETRIE: Is Alderman Baron going to vote against the resolution?

Alderman BARON: I shall vote for it, because the proposition was made in such a modest way that I thought I would not do battle with it. I am now opposing the Chairman's statement that he thinks we have deferred it too long. I hope this motion will be carried; but if the Committee propose another reduction, I will combat it to the last inch.

Mr. ROBINSON asked if the Committee had considered the case of outsiders? If the price was reduced for borough consumers, outsiders would feel badly used if they did not get a reduction as well. According to what the Chairman said on a previous occasion, it was possible for outsiders to have a meter inside the borough, and have gas at borough price.

Alderman PETRIE: That is so. We have considered outsiders. I did not think fit to mention them as I had nothing good to offer them; and I thought if I sympathized with them, they might not think my sympathy honest. One of the objections hitherto urged against a reduction in the price of gas has been the fact that outsiders, while getting water at less than cost price, would have gas at too low a rate. The Committee have removed that very reasonable objection by not proposing a reduction of the outside price. We think the price for outsiders is very reasonable.

Alderman SIMPSON said if there was danger of the electric light succeeding, what would become of the capital invested in the gas-works? He agreed with Alderman Baron as to gas being sold to some thousands of people at a loss. In the absence of a cheapening of other illuminants, he thought the price of gas should be maintained so long as there was such a large loss on the water-works. He would not, however, vote against the resolution.

Alderman PETRIE said he need not reply. Alderman Baron's remarks would bear a very strong replying to; but the proper time would be when the next reduction was proposed.

The resolution was then carried.

The reduction will come into operation with the new year. On and after Jan. 1 the prices will be, for prompt payment, under 10,000 feet, 2s. 9d. per 1000 feet net; 10,000 and under 50,000, 2s. 8d. per 1000 feet net; 50,000 and under 100,000, 2s. 7d. per 1000 feet net; over 100,000, 2s. 6d. per 1000 feet net.

THE GAS SUPPLY OF OLDBURY.—The Gas Committee of the Oldbury Local Board reported at the last meeting of that body that it had been decided to pay off £25,000 of the gas-works loan; also that they had determined to supply gas for motive power at the following rates:—Under 100,000 feet per quarter, 2s. 6d. per 1000 feet; and 100,000 feet and upwards, 2s. 3d.

DEATH OF A PLUMBER FROM GAS POISONING.—Last Thursday a plumber named Joseph Oldfield, of Honley, 43 years of age, met with a sad death. It appeared that on the day in question he was engaged in coupling a branch with the gas-main at Neilly Mill, Honley, when he complained of being very ill, having inhaled some of the gas. He was removed to his home; and death ensued before the arrival of the doctor.

THE DISPOSAL OF THE RESERVE FUND OF THE NEWPORT (MON.) WATER COMPANY.—A special meeting of the Newport Water Company was held last Wednesday, to consider a scheme propounded by the Directors for the disposal of the reserve fund (£4000); the undertaking, it will be remembered, having been purchased by the Corporation. The Chairman (Mr. J. Lawrence) submitted the scheme, in which it was proposed that £500 should be given to the Newport Infirmary; £1000 to the Company's Secretary (Mr. Callum); £350 to the Chief Collector (Mr. Shepherd); and £461 to be divided among the clerks, collectors, and employes. The balance of £2000 the Directors (seven) proposed should be allotted between themselves. Mr. Cartwright moved, and Colonel Hair seconded, the adoption of the scheme. After a little discussion, the motion was agreed to.

AN EXPERIMENTAL LECTURE ON FLAME AND SMOKE.

By THOS. FLETCHER, F.C.S.

Last Tuesday a Lecture was delivered before the Manchester Noxious Vapours Abatement Association by Mr. Thomas Fletcher, F.C.S., of Warrington, who took for his subject "Flame and Smoke."

Mr. Fletcher commenced his lecture by a lengthy quotation from a recent editorial in the JOURNAL, entitled "Invisible Fog" (see ante, p. 793); remarking that the quotations, if not agreeable and reassuring to the Association before whom he was appearing, were at least sound common sense, and they must be faced thoroughly if the Association is to do the work it is intended to do, and to justify its existence. Proceeding, he said: In new processes and new adaptations, it is best to make haste slowly; and those who have any real interest in the abatement of noxious vapours may well be asked to be saved from their friends. As an example, in the *Manchester Courier* for Nov. 16, is a very well written letter, in which the writer states plainly and clearly that "the firing of steam-boilers by gas from a gas generator is the most economical way of producing steam." Now I take it for granted that the writer, from his profession, is not a steam-user, and that he does not speak from actual knowledge. On the contrary, Mr. J. Emerson Dowson, who is a maker of generators, whose business it is to push the use of generators for his own profit, stated at the Bath meeting of the British Association, on Sept. 8 last,* that he was aware "that several attempts had been made to heat boilers with gas of this kind; but so far as his knowledge went, none of them had been successful from a commercial point of view." I myself know of three cases where plant has been put down specially to produce gas for boiler heating. Two of these were failures of the most decided kind. One is, I believe, still working. But it is on a small scale, in the works of a public company paying very large dividends; and although repeatedly promised the figures as to work done for the fuel consumed, I have never been able to obtain them. I examined the whole arrangement carefully, and should be surprised if the same work could not be done by direct firing, with half the fuel used.

Another point in which the advocates for change are doing us a doubtful service is by pressing the claims of generator or water gas as a fuel for domestic purposes. This has been done in America to a limited extent; and the result, as given in *Industries* for Nov. 16, is anything but reassuring.

Both generator gas and water gas are extremely poisonous, owing to the large quantity of carbonic oxide they contain. According to Pettenkofer, air containing one five-hundredth part of its bulk of carbonic oxide is fatal to human life; and that this is an element in the question is proved by the figures given in the above-mentioned periodical, in which it is stated that the deaths from poisoning by water gas, in New York only, in the three years ending December, 1887, were 80, whereas from coal gas only one death occurred in the same period.† One curious and very misleading argument used by the advocates of water gas is that plants will live and thrive in a room lighted and heated by water gas, whereas, they will not do so where coal gas is used. This is simply a special pleader's argument. The requirements are entirely different. Some plants will live and thrive in a cold wet bog during winter, but human beings will not; the fact being that water gas contains rather less sulphur, and produces a larger proportion of moisture than coal gas whilst burning, both of which points are favourable to plant growth. The fact that the burnt gas is not injurious to plants does not affect the deadly nature of these gases to human life in case any escapes unburnt.

Whilst on this subject we may dispose of another wild statement of the anti-smoke agitators—i.e., that "carbonic acid is poisonous," a statement often repeated by many who ought to know better. If carbonic acid were in itself poisonous in the smallest degree, animal life would be a simple impossibility, as the lungs of all breathing animals contain always a large quantity. It exists in a large proportion in the air exhaled from the lungs; and as this is not expelled entirely from the air passages, it must of necessity be re-inhaled at the next inspiration.

As with smoke and noxious vapours, the agitators have not taken the trouble to separate and distinguish between the action of carbonic acid, which is *nil*, and that of the objectionable and dangerous germs which accompany it when exhaled from the lungs of living beings. If anything is to be done worth the doing, the actual facts and difficulties must be faced properly, with a full and practical knowledge of what really can be done, and what is necessary.

THE JOURNAL OF GAS LIGHTING says: "The gas-stove does good no doubt, so far as it goes." This, although literally correct, is rather disposed to cause a false impression as to how far it does go. The production of gas-heating appliances, since the manufacture has been conducted on something like a scientific basis, has become a large and important industry; and, from my own knowledge, I can safely say that the gas cooking and heating appliances in daily use in this country can be counted by millions, and the demand shows no sign whatever of falling off, but very much to the contrary. As regards the abatement of noxious vapours, if we exclude these gas-heating appliances, it is a very great question whether any real good has been done. Probably the result has been the other way, as it has led popular attention to black smoke only as being the cause of all our evils; the fact being that pure black smoke, uncontaminated with other products of imperfect combustion, does very little harm, except so far as it interferes with cleanliness. Being visible, it has become connected in the popular mind with other and far greater evils, which are in reality not necessarily connected with it in any way; and a broad and very positive line should be drawn between black smoke and other products of imperfect combustion and noxious vapours.

To illustrate this, I have here an ordinary type of regenerator burner for lighting purposes, which, under ordinary and satisfactory conditions, gives a clear light without the formation of any solid or offensive products of combustion. If the gas supply is increased slightly beyond the quantity the lamp is designed to burn, we obtain a large quantity of dense black smoke. Now, this smoke is simply pure carbon. It has no more objectionable features than ordinary fine dust, except that it is more visible on account of its colour; and owing to its extreme fineness, it is rather more difficult to remove with a duster. It is perfectly free from smell; and is no more objectionable in a room than a similar quantity of dark dust. I have been quietly working in a room with a regenerator lamp which suddenly began to smoke, without perceiving any change whatever, until the light appeared to fail. On looking up, I found the room filled with dense black smoke; the effect other ways being quite inappreciable.

This is one of many illustrations which could be given that pure black smoke is, apart from its colour, for all practical purposes unobjectionable. We will now take the other side, and see what may accompany black smoke, or what without smoke may arise from imperfect combustion; and for the sake of fair illustration, I will take the same fuel—i.e., coal gas—and change the conditions under which it is burnt. Those who wish to test this matter at home may do it in several

* See ante, p. 802.

† See ante, p. 934.

ways. If only an ordinary lighting burner is available, it will be sufficient to suspend in the flame by a wire a rather large block of pumice-stone. If this is placed low enough to break up the form of the flame, it will cause imperfect combustion, and the formation not only of black smoke, but also of carbon monoxide (which is a poisonous gas) and some most offensive smelling hydrocarbon compounds. A still more powerful demonstration may be made by an ordinary atmospheric boiling-burner, which, when properly lighted, gives a clear blue smokeless flame, free from any objectionable odour. If a light is applied inside the tube, the combustion becomes imperfect, and the products are similar to those in the previous experiment, but much larger in quantity; in fact, with the burner I have here, I could render the air of this room most offensive in a short time, with the result that probably more than half the audience would leave the room with a severe headache, although the actual smoke produced would be much less than that given off by the regenerator burner. Another familiar instance is that of a common tallow candle, which, if burning with a smoky flame, simply causes what may be called mechanical smoke. But blow the candle out and let the wick smoulder; and from this little speck of red will be evolved a smell which is anything but pleasant, and this with an entire absence of smoke. Here then is the difference between the comparatively innocent but much abused smoke, and the invisible but offensive noxious vapours. If the latter can be efficiently dealt with, the former will at the same time almost disappear. I do not wish you to think I have any desire to speak in favour of smoke, but simply that it shall be credited with its own evils only.

Black smoke is very objectionable, as is any other form of mechanical dirt; and it should therefore be avoided. But we must bear in mind that legislation on this matter is a very difficult thing; and it is quite possible to "jump out of the frying-pan into the fire," by stopping smoke, and causing in its place the production of carbon monoxide and other poisonous and offensive compounds of carbon. There is a good deal of truth in the remarks of an old gardener of my acquaintance, who had worked in the same place for some thirty years, that before smoke-consuming furnaces were used his plants got dirty, but since the manufacturers on the windward side had commenced to consume their smoke, they did not dirty his plants, but only killed them. The smoke was replaced by vapours which killed his plants and ruined his garden.

First amongst the evils is the sulphur which is contained in all ordinary coal. This is the most destructive, and the most unmanageable evil we have to contend with. It combines with the oxygen of the air, forming sulphurous or sulphuric acid; and this all-pervading nuisance can be detected instantly (by litmus test-papers) in the air of any large town, on damp walls, in the gutters, and, in fact, everywhere. So universal is this powerful acid, that I have hunted London over in winter to obtain a book of blue litmus test-paper which had not been coloured red by the sulphur in the air, and failed to obtain it. A book was sent to me direct from the makers in a corked and sealed glass bottle. This I opened whilst in a carriage on the Underground Railway, and in a few seconds the paper turned bright red. I tested the mud in the street, the damp on bricks and carved stone, the moisture on the trunks and leaves of trees in the parks; and the result explained the rapid destruction of stone carving, metal, and everything which could be destroyed by dilute acids. There is, I believe, only one remedy, or rather method of reducing the evil, and that is by reducing the total coal consumption in the country; and there is hope in this because a reduction in coal consumption means a saving in money. It is useless to talk about the reduction of smoke, or of noxious vapours, unless we can show the offenders very clearly that a profit is to be made by their prevention. All methods of fuel saving are steps in the right direction—provided, of course, the production of noxious vapours is not increased, as it certainly may be under some circumstances.

Take, for instance, some gas-engines. Their great economy in fuel is undoubted; but note the care with which the users lead the burnt gases outside, for the benefit or otherwise of their neighbours. The poisonous stench evolved by some of them is not easily forgotten if once encountered; and this serious question has been quietly ignored by the makers of gas-engines, who have the commercial tact to know that if their customers get the power, it is a matter of indifference who gets the stench evolved. As regards sulphur, gas-engines are a great improvement. In the first place the quantity of fuel used is very much less for the same power; and the gas is almost entirely free from sulphur. But really perfect combustion is difficult if not impossible in a heavy metal cylinder; and it is probable that the gas-engine of the future will be very different to the present type. That coal gas can be burnt without nuisance we all know; otherwise it would not exist for lighting purposes. That it can be made offensive I have shown you; and, therefore it would not be unfair to insist that all gas-engines should to a great extent be free from the objection which certainly now exists with many of them. With regard to steam-boilers and furnaces, there is no doubt whatever that they can be made smokeless, either by using gas coke as a fuel, as we ourselves do, or by a proper system of firing, such as may be seen on any ordinary locomotive; and there is no doubt, also, that either method can be made profitable. But, on the other hand, there are industries which apparently cannot be carried on without the production of smoke and noxious vapours.

As an instance of this, the manufacture of puddled iron may be taken, which requires to be kept during the whole process in an atmosphere containing a large proportion of uncombined carbon. Possibly, as a total, the greatest offenders are ordinary kitchen chimneys; and in this opinion I am confirmed by many observers who have closely studied the question. The fire is more or less surrounded with metal, the cooling effect of which prevents perfect combustion in its vicinity; and the same objection exists to a greater or less extent with all fire-grates which are not entirely lined with fire-clay. It is only necessary to look over a closely-built town or village on a clear, bright morning to see where a very large proportion of the nuisance arises, or to visit a hilly district, where we can get above the level of a number of ordinary house chimneys, to appreciate the very unpleasant nature of the products of imperfect combustion which arise, and which always must arise, from slow and imperfect combustion. But the tide in favour of the use of coal gas for ordinary domestic heating and cooking purposes has set in so persistently, and on so large a scale, that what has been already done must have a decided effect on the general cleanliness of the atmosphere. It may safely be said that coal gas is not by any means at its lowest ultimate price, and that every reduction in price will cause a large increase in the demand for heating purposes and uses other than lighting. In this respect we are decidedly behind some of our own colonies. For instance, in Melbourne one-third of the total gas made is used during daylight.

There are many points and peculiarities about the combustion of coal gas which are little known; and there are yet many things which remain to be discovered. One important point, which is usually overlooked, is that the size of a flame has nothing whatever to do either with the gas consumption or with the amount of work which can be obtained from it; and I will give you some illustration of this with different burners, each consuming approximately the same quantity of gas. In the first place, I will take a quantity of gas unmixed with air, and burning on a broad surface

of gauze. I must apologize for introducing what is now an old experiment; but it is necessary to illustrate the subject properly. The flame obtained is large and luminous, but as a heating agent it is almost useless; as, if we place any vessel over it, a deposit of carbon would take place (as you see), preventing the passage of heat to the vessel. If I mix a small quantity of air with the gas, the flame increases in bulk, but not in temperature; in fact, there is only an outer film of flame, which is very deceptive in appearance. I can prove that the flame is cold in the centre, by protecting my hand from the outer film of flame, and putting my bare fingers inside it; and again, by putting a parcel of gunpowder inside, which, as you see, remains unburnt. Not only does no flame exist inside, but flame is not even possible; as a burning paper is actually extinguished, and I cannot carry a light into the flame. The fact is that a mixture of coal gas with a small quantity of air will neither explode nor burn, nor will it even support combustion; the flame being caused and supported entirely by the external air surrounding it. That the unburnt mixture exists is easily proved by leading a part of it out of the centre of the flame by a tube; and igniting it at the top of the tube; thus forming a separate and independent flame. That this flame is also hollow, and contains an unburnt mixture, I will prove by leading it out with another smaller tube; making thus a third independent flame from the unburnt gases existing in the first flame. If I increase the proportion of air, I obtain a mixture which will burn without assistance from the surrounding air; the flame becomes at once smaller and solid to the centre, and explodes the gunpowder.

It is possible to produce, with another fuel—*i.e.*, ordinary proof spirit—a much colder flame than can be obtained with coal gas. This I will show you, by saturating a cotton handkerchief and setting fire to it. The flame, although large and important-looking, is so cold that it has not the power even to scorch the handkerchief, which comes out of the trial unharmed. We will test this flame further, and take a ball of explosive gun-cotton, saturate it with the spirit, and set it on fire. As you see, the spirit burns away without having the power to ignite the gun-cotton.

Returning to gas, I will now burn the same quantity as before, in a blowpipe supplied with air under pressure. You see that the flame is again greatly reduced in size; and you can at once judge of the greater intensity of the heat evolved by the ease with which I fuse this mass of iron wire.

In using gas and air as a fuel, we have always to contend with the inert nitrogen which forms four-fifths of the bulk of the ordinary atmosphere. A simple and cheap method of removing this nitrogen is now being worked by the Brin Oxygen Company; and carrying out experiments to the highest limits yet attained in practice, I will show you the same quantity of gas burning with air under pressure, from which this nitrogen has been removed by the Brin process—nearly pure oxygen alone being left. Note, again, that the flame is much smaller even than before; but this aggressively noisy little flame is a power before which few things will stand. Thick copper plates flow before it like water; strong steel boiler plate is fused and perforated in less than a minute; refractory fire-clay is fused into a glass; and a block of lime—one of the most refractory and infusible substances in Nature—although it will not fuse, emits a light of blinding intensity, which gives a fair idea of the actual heat of this insignificant-looking flame.

In flames, as in many other things, we must not judge by appearances, but only by results; and my experiments have very clearly proved that in coal gas we have a source of heat at command which is capable of filling all requirements, and has the special advantages—which are peculiar to itself—of being cleanly, ready for instant service at any time, capable of being used with proper arrangements without the slightest nuisance, and (what is of the utmost importance) costing absolutely nothing except in direct proportion to the service required at the time. We have here a fuel at command for our workshops and our houses which will do perfectly all the heating required in ordinary domestic service, including fires, cooking, bath heating, washing, ironing, clothes drying, and at the same time will light our houses brilliantly; whilst, for workshop purposes, brazing, soldering, small furnaces, and other work, it is a fuel unequalled by any other known. With proper but very simple arrangements, it will do the whole of this work without any nuisance whatever. In fact, both as regards the inside of the building and the outside, it is beyond all comparison cleaner and sweeter than any other known fuel; and it does away with the greatest evil, the sulphur which destroys our buildings and metal work, and renders the air of any large town so offensive—this result being attained partly by the greatly reduced quantity of fuel necessary when coal gas is used, but principally by the removal of sulphur from the gas in the process of manufacture.

That failures occur occasionally in the application of coal gas to domestic and workshop purposes, can only be expected so long as its application is so comparatively recent. But these failures are very rare; and they may be set down to the want of experience in the men who have the responsibility of fixing the apparatus, and also to want of practical acquaintance with the nature of the fuel on the part of the users. The knowledge of what is required is now becoming pretty general; and the failures and difficulties are very rare indeed.

My own house and works are, and have been, practically smokeless from the time they were built; and this result has been obtained from the first at a lower cost than if we had used coal. We will allow that no radical change must be made if general success is to be obtained; and taking as a necessary evil the fact that the kitchen fire is in many houses a necessity in winter for other than cooking purposes, we have allowed it to remain in my own house instead of entirely removing it, as was originally intended. It is burning, probably, for about half of each day during about five months in winter. We tried gas coke; but, like many others who have tried it, we gave it up as a failure, owing to several inherent objections to its practice. In its place we now use a mixture of coal and coke; the fire obtained being brighter, cheaper, and cleaner than when coal alone is used. In the hothouse and conservatories we use coke exclusively; and these are the only fires burning solid fuel. For our cooking, washing, ironing, bath heating, and other fires, we use coal gas exclusively. By this arrangement we not only save money, but we carry out in practice the desires of the Noxious Vapours Abatement Association, by using a much smaller quantity of a purer fuel; and, what is of still greater importance to the small household, the dirt and labour in the house are reduced to less than one-half. So great is the saving that the expenditure on the necessary appliances for the complete service of an ordinary house would nearly or quite be repaid in the first year by saving in cost of labour and wear and tear alone.

Let it be distinctly borne in mind that I do not come before you as a special pleader for the use of gas as a fuel because I am a manufacturer of the necessary appliances. The fact is that for more than ten years before I made any appliances for sale for domestic use, I had the same fuel in daily use for every purpose for which it could be economically applied; and during the last 25 years I have made no change whatever, except in adopting more modern and more economical apparatus. Further than this, the whole of the appliances have been from the first, and are now being used in an ordinary house designed for the use of coal fuel;

absolutely no alterations have been made in fittings or arrangements, except as regards laying the necessary gas-pipes where required. In fact, we could return to the complete use of coal, to the exclusion of gas, at five minutes' notice; and we could remove the whole of our apparatus to any other house with equal facility.

I will now, as a final experiment, heat a small crucible full of broken steel files with the blowpipe previously used, and will fuse both crucible and steel—showing you the enormous power of the fuel we have at instant command; the actual weight of fuel used in this experiment being about 1 oz. Those of you who have had to deal with the production of high temperatures by the use of solid fuel will fully appreciate the value of the servant you have at hand, night or day, at any moment, in every place in which coal gas is to be obtained. In the household we may take an equally representative case as a bedroom fire. Who amongst you has not desired that practically unattainable luxury in the absence of gas, a good bedroom fire every night and morning? And yet this can be obtained with gas without the slightest trouble for less than 3d. per day. The people who would go out of a warm sitting-room to undress in a cold bedroom, for the sake of saving 3d., are few and far between. The value of coal gas for this and endless other purposes requires no special pleading; it simply requires to be known, and the necessary information is spreading rapidly. As the knowledge of its value spreads, so will the demand for all purposes.

SALES OF GAS STOCK AND SHARES.

On Friday last, at the Mart, Tokenhouse Yard, Mr. G. A. Wilkinson sold by auction £50,000 of 5 per cent. perpetual debenture stock of the *South Metropolitan Gas Company*. In opening the sale, the Auctioneer referred to the uninterrupted prosperity of the Company, as proved by the steady annual increase in the quantity of gas sold. In 1877 the consumption was 2,928,123,000 cubic feet; and last year it had reached 5,297,054,000 cubic feet—being an increase in the ten years of 2,368,926,000 feet. He also stated that the capital of the Company amounted to £1,991,500; and the debentures, to £550,000. There was a somewhat small number of bidders present, owing, no doubt, as the Auctioneer remarked, to the fact that several large sales of gas stocks had lately taken place, and that consequently many people had bought all they desired of that class of investment. The prices realized were as follows:—£500 sold at £137 per cent.; £500, at £136 10s.; £500, at £136; £500, at £135 10s.; £500, at £134 10s.; £1000, at £134; £500, at £133; £500, at £132 10s.; £500, at £132; £500, at £131; and £44,500, at £130.

Messrs. Graham, of Newport (Mon.), recently sold by auction a small parcel of stock in the *Newport Gas Company*. £180 of "A" stock, bearing a dividend of 10 per cent., was sold at £205 per cent.; and £350 of "B" stock, earning a dividend of 7½ per cent., produced £154 per cent.

On Monday last week, a few of the old £20 shares in the *Grantham Gas Company* were disposed of by public auction—realizing £45 7s. 6d. and £45 5s. per share.

THE CORPORATION OF DUBLIN AND THEIR ELECTRIC LIGHTING SCHEME.

One outcome of the discussion on this subject at the recent meeting of the Dublin City Council (*ante*, p. 1033) has been the publication of the report of an interview that a representative of the *Freeman's Journal* had with the Town Clerk (Mr. Beveridge) as to the precise effect the resolution adopted by the Council would be likely to have.

Mr. Beveridge said it would not affect the general question at all. The proposed loan of £6000 was for the procurement of plant, &c., and had nothing to do with securing all the necessary authority to the Council for lighting by electricity. Provision had been already made by the Corporation for the expenses incidental to obtaining the Board of Trade Licence and other powers; and a moderate provision had also been made to enable the Committee to put in operation a scheme for public lighting. Had the proposal of the Lighting Committee been adopted at the meeting in question, the Corporation itself would be in a position to undertake the establishment of the installation. He believed the proposal to obtain the loan of £6000 was not known to the Council until the day of the meeting; and it originated with the Committee. With regard to private electric lighting, the Provisional Order could not, owing to legal preliminaries, be obtained until next spring is well advanced; and when obtained it will be of no validity until affirmed by Act of Parliament. The Corporation will not therefore be in possession of powers to undertake any scheme of private lighting until August or September next year. The scheme of public lighting, however, can be arranged by specification, which will provide that the capital outlay in the first instance shall be met by the company contracting for the work. The disadvantage of dealing with contractors in this manner will be that the company will charge a larger amount in order to recoup themselves and leave a profit over, within the limited period of seven years allowed by Act of Parliament for the Licence. But he was enabled to say that a substantial instalment of public electric lighting would be undertaken before next winter; and they will in the first instance carry out the lighting through O'Connell Street, Westmoreland Street, Grafton Street, College Green, Dame Street, Parliament Street, Capel Street, Mary Street, and Henry Street. Referring to the general question of the lighting, Mr. Beveridge told our contemporary's representative he had been informed that the Gas Company are losing by their operations up to the present in electric lighting; but he did not think that possible, unless it were due to the limited field of operation. It is for this reason that the Gas Company are striving so energetically to obtain an extension of the area of operation, in order thereby to create a profit. They are not making any effort, however, for extension of powers; as they claim to have powers under the statute which regulates the proceedings of the Company. But the exercise of any such powers would be subject to stringent regulations by the Board of Trade, presuming that the Board recognized any right whatever in the Company to supply electricity except for their own actual premises. Everyone has, of course, power to light his own premises with electricity; but the construction of wires extending the lighting can, however, only be carried on subject to the usual restrictions. The Town Clerk further remarked that it is plainly laid down in the provisions of the Electric Lighting Act that no application for a Licence to supply electricity will be entertained by the Board of Trade unless consented to by the Local Authority. The Gas Company, knowing that the Corporation would hesitate to give this consent, had based their claim to the necessary powers upon a vague provision in their Private Act of Parliament, although that Act was granted at a date when electric lighting as a financial speculation was not thought of. The Gas Company had endeavoured to obtain permission of the Board of Trade to cut up the streets; but the Board had declined to interfere with the Local Authority on that point. The General Electric Lighting Act provides very plainly that in case a Licence be applied for to the Board of Trade, if the Local Authority also applies for a Provisional Order, the Local Authority will obtain preference. Finally, Mr. Beveridge said the whole question was very tersely put by the Lord Mayor in a

recent speech, in which he said that the entire difference lay between having the scheme dealt with by a Company whose sole object was to make a large dividend and by the Local Authority, who only sought to save itself from loss.

THE ELECTRIC LIGHTING EXPERIMENT AT IPSWICH.

At a Special Meeting of the Ipswich Town Council last Wednesday—the Mayor (Mr. J. H. Josselyn) presiding—the Paving and Lighting Committee submitted a report, in which they stated—referring to their report on the subject of electric lighting presented to the Council on Oct. 24 last, and to the resolution passed by the Council thereon, to the effect that they were prepared to comply with the application of Messrs. Laurence, Paris, and Scott, Limited, for permission to lay cables for electric light and power purposes under the footways along the streets and places specified in the report, on an agreement being entered into by the applicants in such form as Counsel might advise—that on the papers being placed before Council, with instructions to prepare the necessary agreement, he advised that it should not be proceeded with, and that it would be better, and in the end less expensive for the promoters to obtain and carry out their works under a Licence or Provisional Order, as provided in the Electric Lighting Acts. The opinion of Counsel was placed before the promoters, who acquiesced in the views expressed in it; and they had now applied to the Committee for the consent or approval of the Council to an application which they propose to make to the Board of Trade, as early as possible, for a Licence or Provisional Order enabling them to supply electricity within the borough. The Committee were of opinion that the Council should give their approval or consent to this application; but as it was necessary that the approval of the Local Authority to the application to the Board of Trade for a Licence must be given by a resolution passed at a special meeting of the Authority, held after one month's previous notice of the same had been given, no resolution, the report stated, could be passed with regard to it until the meeting which, at the request of the Committee, the Mayor has convened for the 9th of January next. The report concluded by saying: "It is obvious that, under the most favourable circumstances, many months must elapse before the promoters can obtain a Licence or Provisional Order; and as their arrangements will enable them to supply the public with electricity at once, if they are permitted temporarily to put up overhead wires, they have applied to your Committee, under section 14 of the Electric Lighting Act, 1882, for the consent of the Council to their placing electric lines above ground along, over, or across any of the streets of the borough. Under the circumstances, your Committee recommend that this application be acceded to, the permission to be for twelve months only; the wires to be carried over any street at such height as your Committee may in each case approve; the promoters undertaking in the meantime to take all necessary and proper steps to obtain a Licence or Provisional Order."

Mr. GRIMSEY, in moving the adoption of the report, said he might perhaps mention that some few years since an application was made by one of the then numerous electric lighting companies for permission to bring the light into the town of Ipswich. The assent of the Council was asked to making the necessary application for a Provisional Order; and it was ultimately given under certain conditions. Their conduct on that occasion, he thought, might be taken as an indication that they were anxious to give every facility for the introduction of the electric light. The first attempt, however, came to nothing—the Company failing to provide the light within the time allowed; and the ground was left entirely free for any other person to make application. Messrs. Laurence, Paris, and Scott were ready to go on with the work forthwith; and the substance of the report before the meeting was that the Company should be granted temporary permission to put up overhead wires. Thinking that some observations might be made with respect to overhead wires, he had read the report of the Select Committee of the House of Commons in 1885; and this body came to the conclusion that the risk of danger to the public from overhead wires had been greatly exaggerated—the accidents having been few and insignificant.

Alderman NICOLSON, in seconding the motion, expressed the hope that the Council would offer every facility to their fellow-townsmen for obtaining the electric light at the earliest possible date. He did not think that any danger would arise from the mode in which the Company proposed crossing the streets.

Mr. JEFFRIES said he presumed, in giving the required permission, it did not embody a consent for the erection of posts for carrying the wires. While they all wished to see the town well, efficiently, and cheaply lighted, it behoved the Council to be very careful what permission they gave.

Alderman WRINCH remarked that they could not dissociate the resolution before the Council from the question they were to consider on Jan. 9 next, with reference to the application for a Licence or Provisional Order. He was entirely in accord with the opinion that the Council should give every facility for bringing the electric light into Ipswich; and what he wished to learn, at an early stage of the proceedings, was whether, by giving their approval or consent to the present Company to apply to the Board of Trade, the Council would be granting a monopoly to that Company, or whether it would be open to any other company to compete with them.

The MAYOR replied that he was advised by the Town Clerk that it would be open to any other company to compete.

The TOWN CLERK: Except so far as the Board of Trade might otherwise direct. But that, of course, is beyond our control.

Mr. D. FORD GODDARD remarked that it was undoubtedly open to two or more companies to compete before any one of them had obtained a Licence or Provisional Order; but he was not sure whether the same freedom existed afterwards. Was he not right in supposing that both the Licence and the Provisional Order conferred a right to the sole supply of the electric light—the one for a limited, and the other for a longer period of years.

The TOWN CLERK said that it was open to two companies to have each a Licence or Provisional Order. He did not think that either necessarily conferred a monopoly.

Mr. GODDARD observed that there were no cases in which two Provisional Orders or two Licences had been granted for the same town.

The MAYOR said he was sure it would be to the advantage of the town if the Company were given the required permission. The town had very good gas at present; but competition with the electric light would probably result in the supply of still better gas.

The resolution was carried unanimously.

Mr. GODDARD, at a later stage of the proceedings, said that the Council would be asked, on Jan. 9, to give their approval or consent to an application to be made to the Board of Trade by a certain Company. Did that mean that the Council would withhold opposition; and if so, would the form of Licence or Provisional Order be laid before them previous to the meeting? Would they have an opportunity of opposing any clause?

The TOWN CLERK said he had no doubt the Council would have every opportunity of examining the form of Licence or Provisional Order before it was granted. The consent of the Local Authority was a preliminary step which the Company were compelled to take in order to obtain *locus standi* for making an application; but proper notices must afterwards be served upon the interested parties, including the Local Authority, who would, of course, be heard upon the merits of the Licence or Provisional Order. It was difficult for him to say whether a monopoly would be created. The whole thing was in the hands of the Board of Trade, who had certainly the power, as he read the Act, to grant Licences or Provisional Orders to two companies for supplying the same area. Whether or not they did so, would probably depend upon the special circumstances of the case—how the first company were fulfilling their obligations, and so forth.

Alderman MASON asked whether in giving permission to apply for this Licence or Order, it would necessarily apply to the whole of the town, or be confined to a certain portion? In the latter case, the Council would not be giving any person a monopoly of the whole town.

The TOWN CLERK thought the area could be limited. The same question was mooted when the electric light application was considered before; but it was pointed out that it would only pay to light the centre of the town, and that, even if limited to that area, it might have the effect of shutting out any other company.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON. GROWING DISSATISFACTION IN THE COUNCIL.

At the Monthly Meeting of the Leamington Town Council last Monday—the MAYOR (Alderman S. Flavel) presiding—an animated discussion respecting the electric lighting of the town ensued on the presentation of the minutes of the Watch Committee. These stated that the “Committee were strongly of opinion that a decision should be at once arrived at on the subject of the recent experiments by the Electric Lighting and Power Company, and that the Council be requested to ascertain immediately the cost of the three alternative systems used, and bring to an issue forthwith the question of adopting one or the other, or rejecting all of them.”

Alderman WACKRILL moved the adoption of the report. In regard to the electric lighting experiments, he said that the Committee thought there had been time for everyone to judge of the effect of the various kinds of lighting tried. This being so, the Committee considered the Council should take steps to endeavour to ascertain the cost of the three systems; so that they might be able to discuss them on their merits. At present he had no estimate of the cost of the systems; and the Surveyor informed the Committee that, as yet, no estimate had been sent in by the Electric Light Company. He therefore thought it would be well to wait until they knew the actual cost of the different systems.

Alderman GILBERT, in seconding the motion, said the town was anxiously waiting to know what was going to be done with respect to the electric lighting experiments which had been carried on in the main thoroughfare of the borough. He happened to be the member of the Watch Committee who moved the clause which suggested that the Council should be urged to at once put in action any powers they possessed for bringing the Electric Light Company “to book,” as to what terms they were going to offer for the three alternative systems which had been tried. He was glad that he succeeded in getting this clause embodied in the Committee’s report, because it would give every member of the Council an opportunity of saying what they pleased on this important question. He believed that there was a Committee appointed, before the 9th ult., to take into consideration this matter. Nothing, however, appeared to have been done; and he thought it desirable that this question should come before the Council immediately. If some of them lived on the Parade where he did, and saw the continual flickering of the arc light, they would think it was quite time that the Electric Light Company were asked what they were going to do. The “Sunbeam” lights appeared, so far as he could judge, to be the most steady light, and one that the Council might accept if the terms suited the ratepayers’ pockets. The arc lights gave a splendid light when they were all right; but, at varying intervals, they gave very little light at all, and then suddenly there would be a brilliant glare. In Bath Street there were what might be called double burners; but the ratepayers in that locality were not at all satisfied with them. He thought it desirable they should at once appoint a Committee to ask the Electric Lighting Company to tell them, in a very short time, the cost of the three systems of lighting, and also what they purposed doing in the future.

Mr. FELL agreed with a good deal that Mr. Gilbert had said; but he did not think it would be wise to discuss the matter until they had before them statistics as to cost.

Mr. CROWTHER DAVIES said he was very glad to see the recommendation of the Watch Committee. It had always been a great grievance with the Electric Light Company that those who criticized their system of lighting, according to Mr. Chamberlain, went out of their way to reflect upon their ability as electrical engineers. He should hesitate very much, either in his seat on the Council or elsewhere, before he made a public reflection upon a man, or a firm, acting in a business capacity. He thought there was a very glaring comment upon that grievance of Mr. Chamberlain’s in the front of the Town Hall. It was expressly stipulated, and it was distinctly promised, that the arc system exhibited by the Company should be as good as it could be—that was to say, there should be no doubt it should be presented as perfect as the arc system could be. He was not reflecting upon the electrical skill of the Electric Lighting Company; but he asked the members of the Council to see the exhibition of it night after night, outside the Town Hall. There, one of the four arc lights was invariably unsatisfactory; two, frequently; three, sometimes; and four, occasionally. (Laughter.) Would anybody think he was speaking too warmly, or with too much emphasis, when he protested, in as firm a manner as he could, against it being assumed that the exhibition of these four arc lights was any real exhibition of what the arc light could do. He thought there was a pretty general consensus of opinion that the system in force in the Upper Parade afforded a very beautiful light. He had gone out of his way to ascertain informally what the “Sunbeam” light would cost if adopted on the Parade. The estimate was approximate only; but he was assured that it came from head-quarters. If then the Parade was efficiently lighted by the “Sunbeam,” it would cost the ratepayers very close upon £600 a year. This was the only one of the three systems that was likely to be adopted; and he was convinced the ratepayers would not stand it at that price. He was sure they would not adopt the arc system, which was one of the worst he had seen; and he was certain they would not stand the old single light, or the inefficient double one in Bath Street. It was ridiculous to suppose that the little glass globes, with a little bit of red-hot wire inside, would ever be such an advertisement as would attract people to Leamington. Why they would not attract a moth, much less a visitor. (Laughter.) He hoped the Electric Light Company would be able to quote such a price for the “Sunbeam” light as the Council could accept. But he was afraid from what he heard of the cost, and the frequent renewals of the filament (which, he believed, had to be renewed

every three months) that the Company could not name a price which would pay properly, and which the Council would be willing to give.

Mr. B. WHITE said that, about two months ago, he made the same suggestion that had now been made by the Watch Committee, that the Town Clerk should ascertain the relative cost of the three different systems of electric lighting; and he was laughed at then. Messrs. Chamberlain and Hookham undertook that the experiments should not for a month be regarded as a breach of their contract. He wished to ask what was now the position of the Council, as that month had long since expired.

The SURVEYOR stated that the month’s experiments agreed upon would not end until the following Thursday night.

Mr. FELL complained that some of the electric lamps were not giving a light of even 6 candles. He held that there should be power in the contract for the Corporation to clean the lamps, and charge the cost to the Company, if they neglected to do so. Some of the lamps were simply disgraceful.

Dr. THURSFIELD agreed with Mr. Davis that the arc light exhibited was very bad indeed; and he thought that there were very much better arc systems. If Messrs. Chamberlain and Hookham could supply a better arc system, he should like to know what would be the cost, particularly as he was given to understand that the “Sunbeam” had this defect, that the longer it was burnt the dimmer it got, as the filament of carbon burnt deposited on the glass, and so a portion of the light was obscured. He understood the life of a lamp was very short, which made maintenance and renewals very costly.

Mr. JOHNSON inquired what would be the position of the Council on Thursday, when the experiments would end.

The TOWN CLERK: You will have to revert to the contract; and they will have to give you 16-candle electric lights.

Mr. JOHNSON: The sooner notice is given to stop that the better.

Alderman WACKRILL, replying on the discussion, agreed that the arc light was a most miserable failure. They were all apparently pretty well agreed as to which gave the best light; but, before they could decide upon anything, they wanted to know definitely what would be the cost.

The report of the Committee was then adopted.

ALLEGED LEAD-POISONING BY THE BRADFORD CORPORATION WATER.

A number of cases of lead-poisoning have occurred recently in some of the out-districts supplied with water by the Bradford Corporation. In addition to those referred to at the meeting of the Birstall Local Board (noticed below), cases of lead-poisoning have occurred in the district of the North Bierley Local Board. Dr. Whitterton, the Medical Officer to the latter authority, states that he has had several cases reported to him by other medical men in his district; and not being thoroughly satisfied, after examining the cases so reported, that they were due to lead-poisoning, he recently sent to local analysts two samples of water drawn from mains in different parts of his district. In each case the result has proved the presence of lead in small quantities. Many complaints of the condition of the water have recently been made to medical officers in the out-district; and in almost every case where such is practicable, people are ceasing to use the water. Complaints will be made shortly to the Bradford Corporation by several local boards in the out-districts.

At the meeting of the Birstall Local Board yesterday week the Medical Officer (Dr. Forsyth) reported that during the month he had had many complaints as to the quality and purity of the town’s water; and some that he had examined contained slight traces of lead. He recommended the Board to have some water taken direct from the mains and examined by a public analyst as to its purity and fitness for use. Mr. Lister said that in the lower parts of the town the water was filthy and quite unfit for man or beast to drink. He had an idea that the Bradford Corporation were not sending them the high-level water at the present time. Mr. Mason remarked that the Board had spent much money in appliances for cleansing the mains; but for nearly three years those appliances had not been used. If they were used oftener, the water would be improved. Mr. Senior said it was time the Board took action in the matter. He had knowledge as to one serious case in Birstall of lead-poisoning. The man had been in Leeds Infirmary for a month; and on Saturday the Infirmary officials wished to remove him in order to make room for thirty like patients from Pudsey, which was being supplied with the same water as Birstall. There were also a few cases in Gomersal and Drighlington of the same character. He moved that samples of the water be taken before it entered the Board’s reservoir, and also from the mains in other parts of the district, and analyzed; the Water Committee to take such further action as they thought necessary. Mr. Lister seconded the motion. Mr. Lawrence (Chairman of the Water Committee) said he had not heard of any cases in Birstall; but he had from Howden Clough. He had been informed that in the case referred to by Mr. Senior, the man’s illness had been caused by his practice of leaving water in a copper kettle all night in readiness for the morning. The motion was carried.

The record of the proceedings of the Water Committee presented at the meeting of the Bradford Town Council last Tuesday contained an item to the effect that the Town Clerk had made arrangements for another visit to the Bradford watershed by Dr. Tidy, in order that this gentleman might prepare another report on the state of the water. The visit had been arranged for the 17th inst.; and it had been decided that the deputation which had joined him on the former occasion should again accompany him. Alderman Holdsworth, the Chairman of the Committee, in moving that the minutes should be adopted, said that no doubt many of the members had seen a report in the newspapers of that morning with regard to lead-poisoning from Bradford water in some of the out-districts. So far as the Committee were concerned, they had had no complaint whatever from these districts. Further than this, the water discharged out of the mains contained no lead whatever. As to the statement that the water was filthy, the Committee did not send out the water in such a condition. He thought that if the cases of alleged poisoning had been serious, some report would have been sent to the Council. He considered that it was only right to allay any uneasy feeling that might have arisen because of the complaints made. Mr. Hope seconded the motion; and the minutes were then adopted.

DISPUTED WATER-RATES AT SKIPTON.—At the Skipton County Court last Thursday, the Rural Sanitary Authority of the Skipton Union sued Mr. John Coulthurst, a Skipton magistrate, for £21 7s. 6d., for water-rates for three half years. The defence was that the plaintiff had not had the supply of water to which he was entitled. The Judge ruled that there was no case to go to the jury; and a verdict was accordingly entered for the amount claimed. A counter-claim was then heard, in which Mr. Coulthurst sued the Sanitary Authority for the sum of £25 damages for the needless expense and inconvenience to which he had been put consequent on the Authority not giving him a proper water supply. In this case also his Honour ruled that there was no case to go to the jury; and a verdict for the Authority was given.

METROPOLIS WATER SUPPLY.

According to the returns furnished to the Registrar-General by the London Water Companies, the average quantity of water supplied daily to the Metropolis during the past month was 157,969,825 gallons, against 154,782,305 gallons in the corresponding month of 1887. The number of houses served last month was 745,662, or 212 gallons per house, and 27·2 gallons per head of the population. In November, 1887, the number of houses supplied was 732,120; and the quantity of water allowed for each person 27·1 gallons. Of the entire bulk of water supplied last month, 78,048,405 gallons were drawn from the Thames, and 79,921,420 from the Lea and other sources.

In his report to the Registrar-General on the quality of the Metropolitan water supply last month, Dr. E. Frankland observes: "Taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health, was: Tottenham, 0·7; Kent, 0·8; Colne Valley, 1·4; New River, 2·3; Grand Junction, 3·6; Southwark, 4·1; East London, 4·4; West Middlesex, 4·6; and Lambeth, 4·7. The Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained, as is usual at this season of the year, a markedly increased quantity of organic matter, as compared with that in the samples of some months past. The increase was least conspicuous in the case of the Grand Junction Company's water. Notwithstanding this increased proportion of organic matter in the river water, all the samples were clear and bright on delivery. The water principally derived from the River Lea, and distributed by the New River and East London Companies, exhibited a corresponding increase of organic matter; the actual proportion present in the New River Company's water was, however, less than in any of the other river supplies. Both samples were clear and bright. The deep-well waters of the Kent and Colne Valley Companies and of the Tottenham Local Board of Health contained, as usual, only a very small proportion of organic matter. The Colne Valley Company's water was softened by treatment with lime before delivery, although the softening had not been carried as far as usual."

THE QUALITY OF THE SOUTH-WEST SUBURBAN WATER COMPANY'S SUPPLY.

In the House of Commons on Monday last week, replying to a question on this subject by Mr. Pickersgill, the terms of which appeared in our issue of the 11th inst. (p. 1023), Mr. Ritchie said: Two complaints have been received by the Local Government Board with reference to the quality of the water distributed by the South-West Suburban Water Company, who supply a very considerable area. The last of these complaints was made by the Staines Local Board in June last. The Local Board admitted that the Company's water was periodically analyzed on behalf of the Company by Professor Atfield, who certified it to be pure; and the Local Government Board have been furnished by the Company with these analyses, which, it appears, are taken monthly. The analysis for October certifies that the sample taken is a most excellent sample of water for drinking, cooking, washing, and steam purposes generally, and for manufacturing operations. The Board have no control over Water Companies outside the Metropolis similar to that exercised by them under the Metropolis Water Acts. I am not aware that a Local Authority has power to claim the right of inspecting the works of this Company. But it is the duty of the Company under the Water-Works Clauses Acts to keep in their pipes a supply of pure and wholesome water; and I presume that the Company would be liable to indictment for failure to comply with this statutory requirement. I cannot give any undertaking that the Government will propose that they should appoint water examiners for the Water Companies in England and Wales outside the Metropolis; but it may well be a question whether, when County Councils have been constituted, it may not be desirable that some such powers should be conferred on them.

THE NEW WATER-WORKS AT RIPON.

The ex-Mayoress of Ripon (Mrs. Baynes) yesterday week performed the ceremony of turning on the new supply of water for the city of Ripon, the works for which have been in construction at Lunley Moor, 6 miles from Ripon, during the last two-and-a-half years, at a cost of £25,000. For several years the city has been supplied with water pumped from the River Ure to a service reservoir at Lark Hill. The Ure water is fairly pure, and has about 11° of hardness; but the cost of pumping has been a constant source of expense and annoyance by the breakdown of the machinery, to save renewal of which the new works were undertaken. The construction of these, which are on the gravitation principle, were entrusted to Mr. R. Carter, C.E., of Harrogate, and comprised the building of an embankment across the Holborn Valley to intercept the water of the Holborn Beck. This, with the filter beds and service reservoir at High Cross, 2 miles from Ripon, was estimated to cost about £15,000; but the great difficulties met with in making the puddle-trench involved additional outlay to the extent of £10,000. The works, as completed, are of a very durable and permanent character; and the reservoir at Lunley Moor contains at the present time quite twelve months' supply of water. The works were entirely carried out during the three years' mayoralty of Alderman Baynes, whose term of office expired in November last; and it was thought a fitting compliment that Mrs. Baynes should be asked to turn on the new supply. As already mentioned, the ceremony took place yesterday week, at the west entrance to the city. There were present the Mayor (Mr. H. M. Thirlway), the members of the Corporation, Mr. Carter (the Engineer) and a large attendance of the public. The ex-Mayoress turned the valve; and afterwards offered her congratulations on the completion of the scheme. The ceremony of presenting a silver key to the ex-Mayoress took place in the Town Hall; the Mayor officiating. Alderman Baynes, in acknowledging the gift on behalf of the ex-Mayoress, reviewed the subject of the water supply of Ripon and the establishment of the present works. The old pumping-works, he said, were carried out in 1864-5, at a cost of £10,000; and they were further improved in 1877-8, under Mr. Hawksley, at a cost of £8320. Pumping from the River Ure was found to be unsatisfactory, owing to the liability of the water to pollution, and the uncertainty of supply; and in June, 1886, Parliament gave powers for carrying out a gravitation scheme. Lord Ripon and other land-owners granted the required facilities; and a permanent reservoir was established, which, if anything, erred on the side of capacity and strength. It had a drainage area of 660 acres. The land purchased was 48 acres, of which the reservoir occupied 27 acres when full, and contained 92 million gallons of water at a depth of 32 feet. The discharging capacity of the pipes was 750,000 gallons per day; while the actual daily supply was 200,000 gallons. The reservoir was 420 feet above the city; and with the breaking of the pressure at High Cross, Studley, 70 feet additional pressure over the old supply was obtained. The estimated annual charge during the next seven years, including payment of the old debt, was

£2406; the income being £1800, and the amount to be charged on the district rate £606. The average charge on the district rate for the last ten years for the old works had been £544. There would be a great saving to the citizens in the softness of the new water (3·4°); while there would be a daily surplus of 200,000 gallons for distribution among fourteen outlying townships (if required) at 6d. per 1000 gallons, which would increase their income largely. At the close of the proceedings, the Mayor and members of the Corporation were entertained to tea by Alderman and Mrs. Baynes.

THE BRADFORD CORPORATION AND THE SUPPLY OF WATER IN THE OUTSIDE DISTRICTS.

Some correspondence has recently taken place between the Clerk of the Liversedge Local Board (Mr. T. Mitcheson) and Mr. W. T. McGowen, Town Clerk of Bradford, relative to the water supply furnished by the Corporation to the Local Board district. In answer to a letter Mr. Mitcheson wrote to Mr. McGowen, asking whether the Bradford Corporation were prepared to release Liversedge from the limits of their water supply district, the Town Clerk of Bradford wrote to the effect that the Water-Works Committee had repeatedly warned the Liversedge Local Board of the fact that their water supply could not be satisfactory so long as the Board was content to accept the leavings of prior takers of water on the same line of service; and that the Committee had as constantly suggested to the Board several alternative means by which Liversedge could have a supply direct from the Bradford works. It was for the Board to determine which of these courses would best suit them; but up to that moment they had never favoured the Committee with their wishes. The Bradford Corporation were not willing to part with any of their customers, as they were pressed to undertake water-works far larger than their own immediate requirements, so as to assist their neighbours; and having incurred such heavy costs and responsibilities, in yielding to such pressure, they thought it most unreasonable that they should be asked to allow a portion of their district of supply to be withdrawn without any default on their part, whilst all their liabilities were to continue. In answer to this, Mr. Mitcheson wrote, on the 16th ult., stating that the Board could obtain a better supply of water at a cheaper rate than Bradford could supply them at. In a letter dated Nov. 20, Mr. McGowen pointed out that the water supplied by Bradford was exceptionally pure; and as to price, possibly some authority having surplus water at the moment might sell it at a loss in order to get a customer. That would soon cease; and the Halifax people, ready as they appeared to invade their neighbour's district, required the Liversedge Board to construct a storage reservoir at their own expense to eke out the supply. He stated also that Bradford supplied Liversedge with water when the latter were in utter destitution as to water, and that it was not usual when one party had undertaken costly responsibilities to assist another, that the latter should seek to evade its fair reciprocal obligations merely because somebody else made an offer proffering to afford temporary advantage. When this correspondence was read at the Local Board's meeting last week, it was resolved to discuss the matter in private; and no intimation has been given as to the conclusion arrived at.

THE CHARGES OF THE SOUTH STAFFORDSHIRE WATER COMPANY.—At the meeting of the Walsall Town Council yesterday week, reference was made to the defeat of the South Staffordshire Water-Works Company's Bill in Parliament last session; and Mr. Beddows asked if it was true that the Company were raising their rates. The Town Clerk said that he had heard so; and so far as he could learn, they were putting up the price a few pence per quarter on many houses. The Council could not interfere; and any private person who went to law might be "landed" in some hundreds of pounds cost over perhaps 1s. a year. He believed the Company were taking advantage of that. In the course of the subsequent proceedings, it transpired that the outlay incurred by the Council in opposing the Company's Bill amounted to £1148.

THE PROPOSAL TO SUPPLY WATER GAS AT HAWES.—Last Saturday week a meeting was held at Hawes, to hear the report of the delegates appointed by a previous meeting (*ante*, p. 943) to visit Leeds Forge, and report upon the practicability of lighting Hawes with water gas. The report was summed up as follows:—"In conclusion we give it as our opinion that on the following points water gas has a distinct advantage over coal or any other gas with which we are acquainted:—(1) Less labour is required in its manufacture, on account of the less complicated nature of the producing apparatus and the rapidity with which the gas is produced; (2) the absence of all bad smells about the gas-works, which would allow them to be placed in any position without creating a nuisance; (3) the quality of the light is much better—it is steadier and purer than that of ordinary coal gas, while there are no bad smells given off in a close room; (4) by reason of the above absence of smell and the greater heating power of water gas, we are of opinion that it is admirably suited for heating and cooking purposes, and we think that in this direction it will be much more extensively used than coal gas; it is also claimed for it that it is superior to coal gas for use in gas-engines. The only disadvantage we notice in the water gas as compared with coal gas is the requirement of the magnesium combs, which are necessary to be removed at periods of about 100 hours of actual burning. But as they are so very cheap and so easily adjusted, we do not attach much importance to it as against the above advantages. On the whole, our conclusion is distinctly in favour of water gas as compared with coal gas."

MR. S. R. OGDEN ON GAS MAKING.—By invitation of Mr. S. R. Ogden, the Engineer of the Blackburn Corporation Gas-Works, the members of the Blackburn Literary Club last Friday week visited the Addison Street station of the Corporation. The party were conducted round the works by Mr. Ogden and his son, who afforded ample explanations of the part played in the manufacture of gas by the different portions of the plant. After the inspection, the company were entertained to tea by Mr. Ogden, who subsequently delivered a lecture in the Literary Club Rooms, on "Gas and Gas Making." The first part of the lecture was devoted to a historical narrative of the progress of gas lighting—from the time of Murdoch down to 1818, when gas-works were established in Blackburn by a private Company, with a capital of only a few thousand pounds. At the present time, said Mr. Ogden, the capital of the Corporation gas-works amounts to £340,000. The Company made no profit for six years. There were no meters then; and the price of gas was fixed by the number of jets used, and the number of hours it was agreed the gas should burn. When meters were first put into use, the price of gas was fixed at 12s. per 1000 cubic feet. Mr. Ogden then pointed out how gas was made—tracing the manufacture of the gas from the retorts until it entered the mains for distribution to the consumers. He said it is calculated that there are about 100,000 gas-jets in use in Blackburn, and remarked that consumers sometimes lost 20 and 40 or even 50 per cent. of the illuminating power through the use of ill-contrived burners. At the close of the lecture, votes of thanks were given to Mr. Ogden for his kindness and hospitality, and to the Chairman of the Gas Committee (Alderman Thompson) and the members for granting permission to visit the works.

THE DETECTION OF WATER LEAKAGE AND WASTE.

THE EDINBURGH WATER TRUST AND WASTE-WATER METERS.
The Edinburgh Water Trust, at their meeting on Thursday last, received a report from their Engineer (Mr. R. Coyne, C.E.) embodying the results obtained in some experiments with waste-water meters. The report stated that test meters had been put on some street service-pipes which supply various individual houses, and also on the main-pipes which supply certain small districts. Before doing so, a careful inspection of the water-fittings was made in the various houses, with the view of having any faulty apparatus repaired; so that there should be no waste from defective apparatus when the meters were fixed. The meters were afterwards inspected at midnight, and were found standing still; clearly proving that there was no waste from either the pipes or the apparatus. A meter was connected to a house in Douglas Crescent (having ten inmates, including servants), for a period of 27 days. The daily average consumption per head was 42 gallons; and the maximum consumption per head in one day was 57 gallons. A meter was connected with a house in the Eglinton Crescent district (having 17 inmates) for twelve days. The daily consumption per head on an average equalled 30 gallons; and the maximum consumption in one day was 36.47 gallons per head. On another house in this district (having twelve inmates) a meter was put on for 20 days; and the average consumption per head per day was 46 gallons; and the maximum daily consumption per head was 75.83 gallons. To a house in the Drumsheugh district (having 21 inmates) a meter was put on for 31 days. The daily average consumption per head was 46 gallons; and the maximum daily consumption per head was 72.38 gallons. In the Dean district, for a house having nine inmates, a meter was put on for 30 days. The average daily consumption per head was 31.8 gallons; and the maximum daily consumption per head was 46.6 gallons. A meter was connected with a house in the Charlotte Square district (having eleven inmates) for 20 days. The average daily consumption per head was 55 gallons; and the maximum daily consumption per head was 61.8 gallons. For another house in the same district (having six inmates) a meter was put on for 20 days. The average daily consumption per head was 85.2 gallons; and the maximum daily consumption per head was 97.5 gallons. In regard to the district meters, one governed for 20 days the north section of Magdala Crescent, containing a population of 76. The average daily consumption per head was 46 gallons; the maximum daily consumption per head, 54.2 gallons. In the Eglinton Crescent (population, 197), a meter was fixed for 21 days. The average daily consumption per head was 44.2 gallons; and the maximum daily consumption per head, 52.4 gallons. In a trial in the Belgrave Crescent district, with a population of 672, the average daily consumption per head was 48.8 gallons; and the maximum daily consumption per head, 52.5 gallons. In the course of the discussion which followed, it was stated that there was absolutely no waste brought out in Mr. Coyne's report—the water was all consumed within the houses. In moving the adoption of the report, Bailie Archibald explained that one of the reasons why they did not accept the offer of the Deacon Meter Company to provide certain meters free of charge was that they wished to be independent. Another reason was that they had plenty of water just now—millions of gallons—running over, obviating the necessity of their going in for any large expenditure in the checking of waste. He did not think they should run away with the idea that, because there had been excessive waste detected in other towns, the same waste existed in Edinburgh. There was waste, no doubt, in even the best regulated supply; but he could not believe for a single moment that anything like half of the supply was absolutely wasted. They had been told that Manchester and Liverpool had done great wonders with this meter; but these towns brought themselves to a water famine by trusting too much to the Deacon meters. However, these large towns such as Manchester, Liverpool, and Glasgow, were not now trusting to the Deacon or any other meter. Glasgow, with their experience of the Deacon meter, had deemed it expedient to go to Loch Katrine for an additional 50 gallons per head, and at an expenditure of one million pounds. There the supply was 50 gallons per head per day, of which 15 gallons were used for trade purposes. The city was at present bringing in a new supply at a cost of £100,000. As near as they could estimate, the Edinburgh supply for public sanitary purposes amounted to 10 or 12 gallons per head. Manchester (which last year, and even this year up till the summer, experienced a water famine) was now making provision for an additional 50 million gallons per day from Thirlmere, at a cost of about 4½ million pounds sterling. Liverpool was also providing an additional supply of 40 million gallons daily, at a probable cost of two million pounds. Comparing rates, the rate in Edinburgh was 6½d. in the pound; while in Manchester it was 9d., and the public water-rate 3d. He thought Edinburgh had great reason to be thankful for the abundance and purity of its supply of water; and they need not be alarmed or believe that one-half of it was going to waste. The report was adopted.

THE "SCOTSMAN" AND THE USE OF THE DEACON METER.

Concerning the utility of the Deacon meter for the detection of water waste and leakage, additional letters to those already published (*ante*, p. 993) have appeared in the *Scotsman*.
Brief but satisfactory testimony of the usefulness of the system is afforded by the General Superintendent of the East London Water-Works Company (Mr. H. A. Hebler), who states that in the districts governed by the meters, the consumption of water per day per head of the whole population was, before the application of the system, 26.53 gallons; and after a thorough inspection by means of the meters, 16.14 gallons—a saving of 10.39 gallons per head per day. The area treated had a population of 68,808.
Mr. J. M. Restler, M. Inst. C.E., the Engineer of the Southwark and Vauxhall Water Company, has also communicated his experience with the Deacon meter. He says that for the last five years his Company had been gradually introducing the constant supply to their districts; having during that time transferred nearly 50,000 houses, and at the present time have 110 meter districts controlled by waste-water meters. The quantity of water supplied by the Company averages 30 gallons per head per day for the whole of their district; but for the month of November, the average daily supply per head for the 103 meter districts working on constant supply was 18.87 gallons. For the same month of 1887, the average daily supply per head to the 65 meter districts working on constant supply was 21.73 gallons; and for November, 1886, the average for the 34 meter districts working on constant supply was 22.32 gallons. He is of opinion that if the constant supply had been given to those districts without the aid of the waste-water meter, it could only have been done by there being a great increase on the average of 30 gallons per head per day, instead of the decrease as shown. He mentioned that the Company propose to transfer 18,000 more houses during next year, and that waste-water meters will be fixed for the whole of these.
Mr. W. de Normanville, Assoc. M. Inst. C.E., the Borough Engineer of Leamington, describes the invention as "most valuable," and the results obtained at Leamington support this assertion. He says that the meters were fixed early in the year; but they have only been used intermittently—practically for about six months. They have been especially useful in

pointing out defective ball hydrants, the waste from which was running away underground, and was thus unknown. More than 100 cases have thus been detected. The following table shows the comparative consumption of water in the town before and after the application of the meters. Half the meters were fixed November, 1887; the rest in February, 1888:—

Consumption of Water in Gallons per Head per Day.

	1886.	1887.	1888.
January	23.7	23.4	18.8
February	23.9	21.1	17.5
March	21.5	22.2	16.1
April	21.3	22.3	17.0
May	20.6	21.3	18.0
June	24.9	27.6	18.1
July	23.5	26.6	16.5
August	24.2	24.0	17.7
September	23.0	24.4	19.4
October	22.0	24.2	17.0
November	23.6	19.7	15.8
December	22.0	20.2	—
Average	22.8	23.3	17.4

In the middle of the current year the meters were not used, nor any inspection carried out.
A marked decrease in the quantity of water supplied per head of the population since the Deacon system has been in use in Penzance is reported by the Borough Surveyor (Mr. G. H. Small). This gentleman gives a table showing—(1) The average rate of supply per head per day for first seven days of testing in the borough; (2) the average rate of supply per head per day for the first seven days in May, 1888; and (3) the rate of supply per head per day on Nov. 21, 1888. With respect to the last column, the records are generally higher than usual; but, as accounting for the excess, he says the Water Inspector has reported sufficient defects in services to cover it, and these are in process of being remedied.

Total Supply in Gallons per Head per Day.

District.	Popula- tion.	Date of First Testing.	Rate per Head per Day (average of first 7 Days).	Rate per Head per Day, May, 1888 (average of first 7 Days).	Rate per Head per Day, Nov. 21, 1888.
Market Jew Street .	1453	Dec., 1885	47.14	24.58	24.89
Alverton	1200	May, 1887	35.45	16.39	18.25
Folly	1500	May, 1887	44.73	17.96	21.40

Clarence Street . . .	150	May, 1887	27.55	20.87	30.60
Windsor Terrace . . .	290	May, 1887	38.00	15.66	17.82
Taroveer Road	2750	May, 1887	38.06	16.34	19.25
Chapel Street	1450	Nov., 1887	28.25	11.29	14.91

REDUCTIONS IN PRICE.—The Directors of the Oxford Gaslight Company have decided to reduce the price of gas on the 1st prox. from 2s. 8d. to 2s. 6d. per 1000 cubic feet.—The substantial reduction of 6d. per 1000 cubic feet (from 3s. 6d. to 3s.) is announced as from the end of the current quarter by the Directors of the Bromley Gas Consumers' Company.—The price of gas in the Cranbrook Gas Company's district has recently been reduced to 3s. per 1000 cubic feet.

PROPOSED EXTENSION OF THE COLNE LOCAL BOARD GAS-WORKS.—Yesterday week, at the meeting of the Colne Local Board, a report was presented by the Gas and Lighting Committee, from which it appeared that negotiations had been entered into for the purchase of the Spring House estate for gas-works extensions; and the Clerk read a letter from Messrs. Hitchen, Son, and Lancaster offering the property for £2000. It was decided that the Clerk should reply agreeing to the price, subject to the Board procuring the necessary powers to effect the purchase.

READING CORPORATION WATER SUPPLY.—At the meeting of the Reading Town Council on the 6th inst., it was reported that the revenue for the last half year showed the balance of surplus profits to be £1816 16s. 2d., after payment of all charges; and this sum was carried to the district rate account. Alderman Andrewes, who had just previously been re-elected Chairman of the Water Committee, in proposing the adoption of the minutes, said the profits this year were something abnormal, owing to decreased expenditure in several departments, and an increased source of revenue.

SUGGESTED ACQUISITION OF THE BRIERLEY HILL GAS-WORKS BY THE LOCAL BOARD.—At the last meeting of the Brierley Hill Local Board, Mr. J. Skidmore moved the following resolution:—"That the Clerk be instructed to write to the Clerks of other Boards, who, not long ago were similarly situated to our own, in regard to the gas supply, and who have now built or purchased gas-works for their towns, and solicit information as to the working thereof, either probable or otherwise, and whether the building or purchase had been the means of reducing rates out of the profits, and giving consumers better gas at a cheaper price, together with any further particulars they may be disposed to give." He said that the motion was simply one for inquiry, and hardly needed to be supported by statistics or argument. It was well known that in many places the gas-works were the property of the local governing bodies, and that they produced revenue which went in the reduction of the rates. It was the duty of the Board to do anything they could to lighten the public burdens; and an inquiry such as he proposed might enable them to take some further step which would tend to this object. Mr. M'Millan seconded the resolution, which was unanimously agreed to.

NORTHERN COAL TRADE.—The demand which usually sets in before the holidays is giving greater activity to the coal trade, especially of Durham. Steam coal promises better for the next year; and one of the chief collieries is asking 9s. per ton, f.o.b. in the Tyne, for large contracts. Second-class coals do not sell freely, however; and small steam coal is very abundant. For gas-coal the demand is now at its highest point; and as the range of freight for steamers is easier, there has been advantage taken thereof, and much more coal has been sent out—indeed, it is years since the shipments of gas coal from Durham have been as heavy as they were last week. Prices vary; but an idea of how they are going may be gained from the fact that a large contract for an Italian town is now under discussion, and there have been tenders sent in which vary from 7s. 6d. to 8s. for best gas coals f.o.b. in the river. It is, however, for shipment during the next few months. Household coals are in moderate demand; but the seasonable weather will improve the demand. In the next week or so, the production of coals generally will be very heavy, as usual before the end of the year; and afterwards it must be expected that there will be a declension in demand for gas coals, for the period of the largest consumption will have been passed locally at least.

NOTES FROM SCOTLAND.
(FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, *Saturday.*

Although Mr. Defries's extraordinary statements in his comparison between gas and oil have been sufficiently exploded by the article in this week's JOURNAL, I am anxious to show how the question is affected by the state of matters in this district. Mr. Defries said "he was not going to prove his case by theories, but by absolute facts which he was prepared to verify." In what I write, I shall only rely upon "absolute facts, which I have verified." He "took it for the purposes of his demonstration" that public gas-lamps cost £3 10s. in large towns, and that the average cost all over the kingdom was £3 12s. 6d.; the price including the supply of gas and the necessary labour to light, extinguish, and clean the lamps. To similarly furnish oil-lamps, he "found the cost to be as nearly as possible £2 7s. per lamp per annum." Now the facts with regard to Edinburgh are that there were, during the year from May 15, 1887, to May 15, 1888, 9183 public lamps in use, for the supply of gas to which the Edinburgh Gaslight Company were paid £7519; and for the same period the charge incurred in lighting, extinguishing, and cleaning the lamps was £3464—making together £10,983. This works out at 23s. 6d., or exactly half what Mr. Defries admits is the cost of oil lighting. I do not wish, however, to draw an unfair comparison between the two systems of lighting; and so I admit that one-half of the lamps in Edinburgh are extinguished after midnight. Adding on that account one-fourth more to the charge for gas which would have been burned had the lamps remained alight till sunrise, the total charge for gas would be £9398 18s., which would work out at 25s. per lamp per annum, or still 19s. less than the sum which Mr. Defries considers a very moderate one for oil lighting. This means that in Edinburgh, if oil were adopted for lighting the public streets, the charge would be raised from £10,983 to £18,436. Leaving the domain of "absolute facts" for that of reason, if Edinburgh be taken as a typical case, and Mr. Defries's estimate of £822,500 to light the whole public lamps in the United Kingdom with oil be correct, then, to retain gas lighting would not entail a charge, as he puts it, of £1,266,750 per annum, but only of £492,127; or a saving, as compared with oil, of £330,373, instead of, as he says, an annual loss of £446,250. The quality of the two lights, I do not refer to, because we have no public oil lighting in this neighbourhood; but I may say, before closing this paragraph, that the advocates of oil lighting can scarcely object to Edinburgh being taken for the purpose of illustrating the value of the two methods of lighting. In the first place gas is dear in it—the rate for public lighting being 3s. 3d. per 1000 cubic feet, less 2½ per cent. discount; and thus no advantage is gained by gas lighting in the comparison. In the next place, the city lies close to the largest oil-producing district in Britain; and therefore oil has all advantages possible.

Since writing the above remarks, I have learned that a beginning is to be made with oil lighting in my district. At a meeting of the Alyth Police Commission on Monday, it was stated by Mr. Lowe, the Convener of the Lighting Committee, that he had been unable to effect some suggested alteration in street lighting, because the Gas Company declined to make the necessary connections. This was supplemented with the information that in Dunoon, 17 out of 245 public lamps are lighted with oil; and Mr. Lowe, at his own request, was allowed to put up "one good oil-lamp, in order to test the result." If the lamp be no better than those in use at Dunoon, which were stated to cost 4s. per lamp, it is not difficult to foretell that the result cannot be very satisfactory.

Regarding the use of Deacon meters for the discovery of waste and leakage of water, as readers of the JOURNAL are aware, the *Scotsman* has strongly urged the adoption of the system in Edinburgh, and has characterized 41 gallons per head per day as a "monstrous consumption." A little touch of humour has been introduced by the Water Trustees into the experiments they have been making with these meters. One of them was fixed on the service-pipe supplying the house of one of the proprietors of the *Scotsman*; and the result has been to show an average daily consumption in that dwelling of 46 gallons per head; and a maximum consumption of 72·33 gallons. In reply, the *Scotsman* impugns the accuracy of the report, contending that the consumption attributed to the house was well high four times the actual consumption, and that the number of inhabitants had not been ascertained and the number given was misleading.

Montrose has just added an addition to the resources of its water supply, which renders the town one of the most desirably situated in that respect. The supply is obtained by pumping; and the new apparatus consists of the substitution of a turbine for an ordinary water-wheel to furnish the motive power for the three pumps employed. It gives 50-horse power, or three times the power of the old water-wheel. A supply of 500,000 gallons per day is provided for, or about double the present requirements of the town.

The Peebles Police Commission have been strongly urged by Professor Veitch, of Glasgow, to oppose the Edinburgh proposal to take in the Manor water supply. The burgh of Peebles is supplied from the Manor; and the Professor is afraid—unnecessarily, I think—that the interests of the town would suffer by the abstraction of a large quantity of water for Edinburgh. The Police Commissioners, while not appearing to share his alarm, have instructed their Clerk to make inquiries, so that they may make up their mind as to whether they should endeavour to secure the whole of the Manor supply to themselves.

The proposal to extend the water supply of Kinghorn, which I mentioned last week, is threatened with opposition at the hands of the Burntisland Oil Company, who are proprietors of the ground required for the new reservoir. The Company wrote to the Town Clerk, asking if the Council would grant them certain concessions, including water free of charge for their works and workmen's houses. To this the Town Clerk replied that he could not recommend the Council to grant the concessions, because it would be, in effect, handing over their water rights to the Company. Thoroughly the Directors of the Company resolved to give the most unqualified opposition to the scheme in all its stages. The Town Council are, however, to proceed with the undertaking.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, *Saturday.*

Last Monday was at times the foggiest day known in the Glasgow district for a number of years; and the consequence was that a very great demand was made upon the supply powers of the three gas-works belonging to the Glasgow Corporation Gas Commissioners. The amount of gas delivered into the city and suburbs over a period of 24 hours was 16,071,000 cubic feet; whereas, for the corresponding period of last year, it did not exceed 14,788,000 feet. But yesterday's delivery even exceeded this enormous total; and it really "beats the record," in respect of the largest days' deliveries in recent years; inasmuch as it amounted to 16,447,000 cubic feet. The greatest consumption on any one day in 1887 was 16,287,000 feet; and the date was the 21st of December—the day immediately preceding the shortest day. In the year 1886, the largest amount of gas delivered in a 24-hour period was 16,266,000 feet; and in the preceding year it was 14,718,000

feet. It is somewhat difficult to account for the enormous delivery yesterday. The morning remained dark for a long time, but there was practically no fog; and had it been a really cold December day, instead of a mild one, as was the case, it is probable that the consumption of gas would have been decidedly greater. The whole week has been characterized by a large daily consumption—15,282,000 cubic feet on Tuesday, 15,523,000 feet on Wednesday, and 15,514,000 feet on Thursday. For the production of the gas represented by the five days' figures just given, there have been in use rather over 1700 retorts, many of which at the Dawsholm works, however, are much above the average size. At the three works there are available for gas making nearly 2300 retorts, and the total producing power may be set down at about 17,400,000 cubic feet, or scarcely a million feet more than the maximum daily consumption. The gasholder capacity, on the other hand, is only about 12,000,000 cubic feet; so that on that matter, it is quite evident that the Corporation Gas Committee have got some work before them to be done. In connection with the large daily deliveries of gas to the consumers, it is worthy of mention that the illuminating power has been decidedly higher than what some persons would have us to believe. Instead of being down at 22 standard candles, it has been registered this week at 23·3, 23·7, 24·5, and 24·6 candles; indeed, taken over all, and when used with really good burners, the gas now available for consumers is of excellent quality, giving a very fine white light. Of course, the production of gas of such high quality involves the use of a certain proportion of rich cannel coal.

It might here be worth while to mention a few statistics as to the recent monthly consumption of gas in the Glasgow area of distribution. In September, the deliveries amounted to 189,138,000 cubic feet, as compared with 173,965,000 feet in the corresponding month of 1887. This was an increase of 15,173,000 feet. In the succeeding month (October), the consumption amounted to 235,959,000 feet, against 253,165,000 in October, 1887. Thus showing an increase for the month of 32,794,000 feet. Last month the deliveries reached the grand total of 366,751,000 feet; whereas in November of last year, the total was 341,596,000 feet—the increase for the month amounting to 24,855,000 feet.

Referring to ex-Bailie Crawford's remarks about "the tyranny of a ring of coalmasters who were possessed of the coal necessary for the production of the higher quality of gas," which were included in the opening paragraph of my last budget of "Notes," I am assured, by a gentleman who ought to know, that no such "ring" has ever existed amongst those coalmasters; and that so far from any such combination existing, the coalmasters who deal in the richer cannels are hardly on speaking terms with each other. Mr. Crawford may not deem it worth his while to say anything in support of the statement which he made on this matter last night week.

On Thursday night no little surprise was caused in the town of Falkirk on account of the comparative weakness of the gas supply, more especially in the northern portions of the burgh. In almost every case jets were reduced to nearly single-candle power; and in some places the lights went out entirely. As a natural consequence, a considerable amount of inconvenience was felt. It is stated that the deficiency in the supply of gas was due, not to any actual scarcity, or to fault on the part of the management, but to the fact that the main gasholder at Canalside failed to sink as the gas left it; thus preventing the supply getting into the distributing plant. From some unknown cause, the chains and pulleys had got out of gear. After some considerable trouble this state of things was rectified; and the supply of gas was continued as usual. It may be added that before the gasholder was righted, a large quantity of gas had escaped, and had the East-end works not been in operation at the time, the town would have been temporarily in total darkness.

I have pleasure in stating the vacancy in the gas examinership at Paisley, caused by the death of Dr. Wallace, was filled up last Tuesday morning, by the appointment of Mr. R. R. Tatlock, one of his former partners. The salary attached to the office is, I believe, £50 a year.

At Johnstone the men employed in the gas-works have just had their wages increased to the extent of a shilling per week. At their monthly meeting on Monday, the Johnstone Gas Commissioners were informed by the Gas Committee that the highest offer received for the secondary products was that of the Glasgow Gas Residual Products Company. It was £290 for the year; being an increase of £50 over last year's price. The offer was accepted.

In consequence of the fire at the Glasgow General Post Office, through some defect, it is believed, in the electric light fittings, about 150 Defries oil-lamps have been introduced—each of about 100-candle power. These are to remain in use till the electric light is again put in thorough working order. It may be remembered that the Glasgow Post Office was the first establishment of the kind to be lighted with electricity; but the so-called "light of the future" has not been an unalloyed success during the seven or eight years it has been in use.

Quietness has been the rule in the Glasgow pig iron warrant market this week; and very little change in prices has taken place. For Scotch iron, the close yesterday was 41s. 8½d. cash buyers.

No particular change falls to be recorded in reference to the local coal trade. Prices keep steady at about 7s. 3d. per ton for main coal, which usually guides the price for other qualities.

TYNEMOUTH WATER SUPPLY.—On Tuesday last a deputation from the Tynemouth Corporation—consisting of the Mayor, Town Clerk, and others—waited on the Directors of the Newcastle and Gateshead Water Company, and asked them to entirely supply the borough of Tynemouth with water. They stated that already the Company supplied five-sevenths of the quantity used; and it was thought it would be better for the inhabitants generally if the whole of the supply came from the Company's reservoirs. The proceedings were strictly private; but it is understood that the Company intimated that they could not see their way to accede to the request of the deputation.

BANKRUPTCY OF A SALFORD ALDERMAN.—A meeting of the creditors of Mr. T. H. Jenkins, an Alderman of the borough of Salford, and an ex-Deputy Chairman of the Gas Committee, was held at the chambers of the Official Receiver (Mr. C. J. Dibb) last Friday. The statement of affairs which the debtor had scheduled showed liabilities amounting to £922 5s. 10d., and assets nil. He attributed his insolvency to "want of employment and losses in shares." At the outset a resolution was proposed adjourning the meeting for a week; and, no objection being raised, this was agreed to. The public examination of the debtor was conducted at the Salford County Court later in the day. He stated that the creditors who served notice upon him were the Grosvenor Building Society, who brought an action against him for a large sum of money, and obtained judgment, which he had allowed to go by default. His principal liabilities had been caused by his unfortunate good nature in joining in a transaction with a person who had received the whole of the money advanced, and left him responsible for it. He had also lost largely in shares. The examination was adjourned to yesterday.

CURRENT SALES OF GAS PRODUCTS.

LIVERPOOL, Dec. 15.

Sulphate of Ammonia.—The state of the market since the beginning of the month makes one doubt whether, after all, the previous upward movement has not been purely artificial; and that it has been greatly provoked by the excitement in nitrate, and by "Bull" speculation, cannot be questioned. To-day prices are down again to the level of the values at the end of October; and it is foretold in some quarters that the lowest point has not yet been touched. The tendency of the market during the rest of the month will, however, much depend upon the quantity which makers intend to place on the market of the balance of their make, on the re-sales of parcels held in second-hands, and the demand from consumers. Sulphate did not advance as much as nitrate, and it has fallen more; hence to anticipate any further serious decline would be unreasonable. The margin between the two is now reduced to below £1 per ton. There appear to be sellers at Hull and Leith at £12.

LONDON, Dec. 15.

Tar Products.—The prices ruling during the week have practically been those of the previous week. If anything, pitch and benzoles have been in better demand; but without much change in price. Crude carbolic is firm at 3s. 10d. and 3s. 11d. Anthracene shows little change. Prices may be taken as follows:—Tar, according to position, 18s. to 23s. per ton. Benzole, 90 per cent., 3s. 1d. per gallon; 50 per cent., 2s. 5d. Toluol, 1s. 6d. per gallon. Solvent naphtha, 1s. 3d. per gallon. Crude naphtha, 30 per cent., 1s. 2d. per gallon. Light oil, 3d. per gallon. Creosote, 2½d. per gallon. Pitch, 18s. to 21s. per ton. Carbolic acid (crude), 3s. 10d. per gallon. Cresylic acid, 10½d. per gallon. Tar salts, 15s. per ton. Anthracene, 80 per cent., "A" quality, 1s. 4½d. per unit; "B" quality, 1s. 2½d.

Ammonia Products.—Sulphate has eased off slightly during the week; and to-day's price is about £12 to £12 2s. 6d. per ton. Prices of other products may be taken as follows:—Gas liquor (5° Twaddell), 8s. per ton, with a rise or fall of 1s. 6d. per degree. Liquor ammonia, 2d. per lb. Carbonate of ammonia, 3½d. per lb. Muriate of ammonia, brown, £18 per ton; white, £25. Sal-ammoniac, £30 per ton.

[From the Chemical Trade Journal, Dec. 15.]

Tar Products.—The tar product market remains unchanged, at least in so far as benzol is concerned; 90's are still quoted at 3s. 2d. and 50/90's at 2s. 5d. This is usually considered the quietest time of the year for this product; and there does not seem to be much business doing even at these prices. Solvent naphtha continues in request at former prices; and makers are now asking 2d. per gallon for good fluid creosote. Crude carbolic acid continues firm, and fairly in request for forward delivery. Anthracene remains as stated in our last report; whilst pitch is, if anything, a shade firmer, as it is rumoured the price is likely to be advanced within a short time. The prices named in our last report may be said to rule to-day.

Sulphate of Ammonia.—There is not much change to report in sulphate. Dealers would have us believe that the tendency is to lower prices; and this may be so, although £12 2s. 6d. has been accepted at Leith, and £12 is about the figure to-day for Hull sales. Stocks at Hull are very light; and many makers have shown the disposition not to embarrass the market by pushing parcels upon it which are not required. After all, it is doubtful whether very much is available; and it is therefore probable that, if makers stand well together, we shall not see any further depreciation in value.

DEATH OF A COLLIERY MANAGER.—We regret to learn that Mr. William Clark, Manager of the Teversal and Plesley Coal and Cannel Pits, Mansfield, fell down the Butcherwood Pit last Wednesday, and was killed.

THE GAS LIGHTING IMPROVEMENT COMPANY, LIMITED.—This is the title of a Company registered with a capital of £20,000, divided into 20,000 shares of £1 each, of which 2000 are founders' shares, and the remaining 18,000 ordinary shares. The object of the Company is "to adopt, ratify, and confirm a certain provisional agreement of Dec. 4, 1888, made between Hiram Stevens Maxim of the one part and George Stanley Sedgwick, on behalf of the Company, of the other part, for the sale by the said Hiram Stevens Maxim to the Company of a certain invention of 'Improvements in apparatus for naphthalizing or carburetting illuminating and other gas;' and to do such other things as the Board may consider desirable."

GWYNNE & CO., ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C.

GWYNNE & BEALE'S PATENT GAS EXHAUSTERS & ENGINES.

Telegrams: "GWYNNEGRAM, LONDON." Telephone No. 2698.

Exhausters of nearly all sizes in Stock.

Prize Medals at all the Great International Exhibitions.

Exhausters equal to a total capacity of more than 26,000,000 cubic feet passed per hour have been supplied by us.

Our new Patent Non-Fluctuating Exhausters, to work without the slightest oscillation or variation in pressure, are strongly recommended.

MAKERS OF EVERY DESCRIPTION OF HYDRAULIC AND GAS MACHINERY.

Gwynne & Co.'s New Catalogue and List of Testimonials can now be obtained on application.

Exhausters and Vertical Engine as supplied for both the Fulham and Bromley-by-Bow Stations of The Gaslight and Coke Company.

OXIDE OF IRON.

O'NEILL'S Oxide has a larger annual sale in the United Kingdom than all other Oxides combined. Purity and uniformity of quality guaranteed. Pamphlet, "How to Purchase Bog Ore," to be obtained on application.

Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C.

JOHN Wm. O'NEILL, Managing Director.

ANDREW STEPHENSON, Agent for the GAS PURIFICATION and CHEMICAL COMPANY, Limited, Palmerston Buildings, Old Broad Street, London, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS.

Prices, &c., will be forwarded on application to No. 80, ST. ANDREW SQUARE, EDINBURGH, } SCOTLAND.
No. 54, BERNARD STREET, LEITH, }

WANTED, A Second-hand Combined ENGINE and EXHAUSTER, Rotary preferred; capacity 5000 cubic feet per hour.

Apply to the DINSMORE GAS COMPANY, LIMITED, Batavia Buildings, LIVERPOOL.

FOR SALE—A Tar and Ammonia Works in Yorkshire. Well situated for obtaining Tar and Liquor. Terms easy.

Address Box 25, Post Office, HECKMONDWIKE.

FOR SALE—The British, American, and all the Continental PATENTS for an excellent CARBON (Naphthalene) GAS-LAMP, either all together or separately.

Address A. Z., 2140, Haasenstien and Vogler, VIENNA.

FOR SALE—As a going Concern, a Small FACTORY in London for the Manufacture of Gas and Electric Light Fittings. Has good connections. Capital, £1000. Exceptional opportunity for a young man or two friends wishing to start.

Apply to E. D., 2, CORTHALL BUILDINGS, E.C.

WANTED, by a young Man (age 27), a Re-engagement as FITTER, &c., in a Gas-Works. Well used to Main and Service Laying, Meter Fixing, and Meter Reading, and would not object to make himself generally useful.

Address FITTER, No. 3, Derby Road, LONDONBOROUGH.

WANTED, immediately, a Young Man as GAS-FITTER on Small Works. Well up in General Repairs on Works, Meter Fixing and Reading, Main and Service Laying, Smithing, House and Stove Fitting, and Lamp Repairs.

Apply, stating wages, references, age, and when at liberty, to

H. WINHURST, Manager.
Gas-Works, Sleaford, Lines.

DRAUGHTSMAN. **WANTED temporarily, a Draughtsman,** thoroughly experienced in Gas-Works.

Applications, stating remuneration required and previous experience, accompanied by copies of testimonials, should be sent not later than Saturday, the 22nd of December, 1888, addressed to No. 1664, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

GAS ANALYST. **WANTED, by a large Gas Company, a GAS ANALYST** who must thoroughly understand Analysis of Gas, Gas Products, &c., and have had a long experience in testing for Impurities and Illuminating Power of Gas.

Applications to be sent to No. 1665, care of Mr. King, 11, Bolt Court, FLEET STREET, E.C.

INSPECTOR. **WANTED, by the Richmond (Surrey) Gas Company, a competent Man as INSPECTOR.** Candidates must have had good experience in Main and Service Laying, Inspection and Testing of Meters, and the general outdoor work of a Gas Company.

Applications, in own handwriting (accompanied by not more than three recent testimonials), stating wages required, age, and present employment, to be addressed to the ENGINEER, Gas-Works, Richmond, Surrey.

Dec. 14, 1888.

LITTLEHAMPTON GAS COMPANY. **WANTED, a good, substantial and thoroughly sound, Second-hand SINGLE-LIFT GASHOLDER** with CAST-IRON TANK, of a diameter ranging from 65 to 80 feet, and of a depth from 16 to 20 feet.

Both the Gasholder and Tank must be in first class condition, and not more than ten years old.

Preference would be given to parties able to quote delivered and fixed complete at the new works of the Littlehampton Gas Company.

Prices and full particulars to be sent to the Chairman of the Company, Captain Mills, R.N., not later than Saturday, the 22nd inst.

A. SNEWIN, Secretary.

Gas-Works, Littlehampton,
Dec. 11, 1888.

SHEFFIELD UNITED GASLIGHT COMPANY.

WORKS SUPERINTENDENT.

WANTED, by the Directors of this Company, an experienced and competent Man to act as SUPERINTENDENT at their Easingham Street Gas-Works.

He will be required to reside on the Works; Hense, Coal, and Gas free. The maximum make of Gas at this station is about three-and-a-half million cubic feet per day.

Applications, stating age, previous engagements, and salary required, to be made by letter only, addressed to Sir Fredk. T. Mappin & Bart., M.P., Chairman of the Company, Gas Offices, Sheffield, not later than Monday, the 7th of January, 1889.

Testimonials not to be sent till asked for.

HANBURY THOMAS, General Manager.
Commercial Street, Sheffield,
Dec. 14, 1888.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock.

For Prices apply to JAMES LAWRIE AND Co. 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLBANK STREET, LONDON, S.W.
[Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gasholders and Meters, Registering and other Gauges, &c., &c.

* See Advertisement on Page III. of the Wrapper of this week's issue.

W. C. HOLMES & Co., Huddersfield, AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings.

* See Advertisement p. 1044 of last week's issue.

Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas-Works prepared by R. D. Gibbs, Summerfield Crescent, Birmingham.

Analysis of Coal, Oxide, and all Gas Materials.

TO CHEMICAL MANUFACTURERS & OTHERS. **TO LET—Extensive Premises,** situate between Wrexham and Ruabon, on a Branch of the Great Western Railway, consisting of Large SHED, 167 feet long by 25 feet wide; BUILDINGS, 37 feet by 28 feet; 67 feet by 27 feet; and 25 feet by 20 feet; WHARF, 100 feet long, with Railway Siding running the whole length. Within easy access, by rail, of several large Gas-Works.

Apply to GEO. E. WOOLFORD, RUABON.

HAWORTH LOCAL BOARD OF HEALTH. **THE** above Local Board are prepared to receive TENDERS for the purchase of the AMMONIACAL LIQUOR and surplus TAR from Jan. 1, 1889, to March 25, 1890, delivered at the Gas-Works, Haworth, and similar TENDERS delivered on rails at Haworth Railway Station.

Tenders, marked "Tar and Liquor Tender" may be sent in to me the undersigned not later than Dec. 26, 1888.

By order,
R. H. WHITELEY, Gas Manager.
Haworth, Dec. 6, 1888.

ALLIANCE AND DUBLIN CONSUMERS' GAS COMPANY, D'OLIER STREET.

THE Directors of the above Company are prepared to receive TENDERS from IRON-FOUNDERS, GUN-BARREL MANUFACTURERS, IRONMONGERS, TIMBER MERCHANTS, DRUGGISTS, ROPEMAKERS, &c., for Goods to be delivered in the Company's Works, Great Brunswick Street, in such quantities as may be required from time to time up to the 31st of December, 1889.

Printed Lists of Articles required can be had on application at the Company's Offices, D'Olier Street.

Tenders, endorsed "Tender for Stores," to be lodged in my Office on or before the 31st inst.

W. F. COTTON, Secretary and Manager.
Dec. 11, 1888.

TO GASHOLDER MAKERS. **THE Directors of the Blaenavon Gas and Water Company, Limited, Blaenavon, Mon.,** invite TENDERS for Providing and Erecting One Single-lift GASHOLDER, 50 feet by 18 feet, with Six Cast Iron Columns and Wrought Iron Lattice Girders, complete with Inlet and Outlet Pipes and Valves.

Persons tendering to provide Drawings and Specification; and submit the same, together with tender, to the undersigned, not later than Tuesday, Jan. 1, 1889.

The Directors do not bind themselves to accept the lowest or any tender.

CHAS. WHITE, Manager.
Gas and Water Works Office,
Blaenavon, Mon., Dec. 14, 1888.

TO GASHOLDER MAKERS. **THE Directors of the Sheffield United Gaslight Company** invite TENDERS for RESHEETING A Two-lift GASHOLDER (115 feet in diameter) at their Easingham Street Station; and also for ENLARGING THE SAME by adding a third Lift thereto.

Specifications and Drawings may be seen on application to, and forms of tender, with bill of quantities, obtained from the Company's Engineer, Mr. Fletcher W. Stevenson.

The Directors do not bind themselves to accept the lowest or any tender.

Tenders, marked "Tender for Repairing and Enlarging Gasholder," to be addressed to the undersigned not later than Monday, Jan. 7, 1889.

HANBURY THOMAS, General Manager.
Gas Offices, Commercial Street,
Sheffield, Dec. 14, 1888.

CORPORATION OF LEICESTER.

CAST-IRON PIPE CONTRACT.

THE Gas Committee of the above Corporation are prepared to receive TENDERS for the supply of the necessary CAST-IRON PIPES and CONNECTIONS, from 3 inches to 24 inches in diameter, required during the Twelve months ending the 31st of December, 1889.

Specification and form of tender to be obtained from the Engineer.

Tenders, addressed to Councillor Lennard, Chairman, and endorsed "Tender for Cast-Iron Pipes, &c.," to be delivered at these Offices not later than Eleven o'clock a.m. on Saturday, Jan. 12, 1889, prox.

The Committee do not bind themselves to accept the lowest or any tender.

ALFRED CULSON, C.E., Engineer and Manager.
Gas Offices, Millstone Lane,
Leicester, Dec. 11, 1888.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour.

Highest References and all particulars supplied on application.

JOHN RILEY & SONS, Chemical Manufacturers, Hapton, near Accrington, are MAKERS of SULPHURIC ACID, from Brimstone, for Sulphate of Ammonia making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitrol. References given to Gas Companies.

CRYSTAL PALACE DISTRICT GAS COMPANY.

NOTICE is hereby given, that the TRANSFER BOOKS of this Company will be CLOSED from the 31st inst. for a period of 14 days.

By order of the Board,
MAGNUS OHREN, Secretary.

Offices, Lower Sydenham, Dec. 14, 1888.

GLASGOW CORPORATION GAS.

THE Glasgow Corporation Gas Commissioners are prepared to receive TENDERS for the Construction at the Tradeston Gas-Works of Two Sets of Four PURIFIERS, each 35 feet square.

The Drawings may be inspected, and copies of the specifications and forms of tender obtained, on application to Mr. William Poulis, the Engineer, 42, Virginia Street, Glasgow, on and after Monday, the 3rd current, upon payment of one guinea.

Sealed offers, endorsed "Tender for Purifiers," and addressed to the subscriber, will be received by him, on or before Monday, the 24th current.

The Commissioners do not bind themselves to accept the lowest or any offer.

J. D. MAHWICK, Town Clerk.
City Chambers, Glasgow, Dec. 1, 1888.

ELLAND GAS COMPANY.

RETORTS AND FIRE-BRICKS.

THE Directors are prepared to receive TENDERS for RETORTS and FIRE-BRICKS required for Twelve months, delivered free at Elland Gas-Works.

Tenders, addressed to the Chairman, and endorsed "Tender for Retorts, &c.," to be delivered at these offices not later than Jan. 4, 1889.

The Committee do not bind themselves to accept the lowest or any tender.

H. S. PIKE, Secretary and Manager.
Gas Offices, Elland, Dec. 13, 1888.

BOROUGH OF DARWEN.

(GAS-WORKS DEPARTMENT.)

TENDERS FOR PURIFIERS.

THE Corporation are prepared to receive TENDERS for the Supply and Erection of Three New PURIFIERS, each 25 feet by 30 feet, with Pillars and Girders complete. Also the REMOVAL of one of similar size, from one building to another.

Plans and Specifications may be seen, and all necessary information obtained from the Gas Engineer, Mr. Thos. Duxbury, Charles Street, Darwen.

Sealed tenders, endorsed "Tender for Purifiers," to be delivered at my Office, on or before Nine a.m. on the 31st of December.

The Corporation do not bind themselves to accept the lowest or any tender.

By order,
CHAS. COSTEKER, Town Clerk.
Town Clerk's Office, Darwen,
Dec. 5, 1888.

FINCHLEY LOCAL BOARD.

TO PUBLIC LIGHTING CONTRACTORS.

THE Finchley Local Board is prepared to receive TENDERS from Public Lighting Contractors to LIGHT by PETROLEUM or other OIL so much of their district as is now supplied with Gas by the Colney Hatch Gas Company.

Plans of the District, showing the number of Lamps required, and the various Roads required to be lighted, may be seen at the Offices of the Board, on application to Mr. Geo. W. Brumell during office hours 9 to 5; and all information necessary will be furnished.

Proposals and tenders to be sent in, addressed to the Finchley Local Board, and marked "Tender for Lighting," not later than Six p.m. on Friday, the 21st of December, 1888.

The Board do not bind themselves to accept any tender.

By order of the Board,
HENRY STEVEN, Clerk.
Offices of the Board, 11, Queen's Terrace,
Church End.

BRISTOL UNITED GASLIGHT COMPANY.

AMMONIACAL LIQUOR.

THE Directors of this Company invite TENDERS for the purchase of the AMMONIACAL LIQUOR to be produced at all or either of their three Stations during a period of One, Three, Five, or Seven years, commencing on the 1st day of July, 1889.

The annual quantities and strengths of the Liquor produced at each of the Stations at present are approximately as follows:—

	Gallons.
Canons' Marsh Station, 1,000,000 of 14 ounce Strength.	
Avon Street " 1,300,000 " 15 " "	
Stapleton " 700,000 " 17 " "	

Conditions of Contract, and forms of tender, may be obtained on application to the undersigned, to whom also tenders, sealed, and endorsed "Tender for Ammoniacal Liquor," must be delivered not later than Ten a.m. on Monday, the 28th day of January, 1889.

The Directors do not bind themselves to accept the highest or any tender.

JAS. V. GREEN, Secretary.
Chief Offices: Canons' Marsh,
Bristol, November, 1888.

WATER SUPPLY, & SANITARY IMPROVEMENT.

TUESDAY, DECEMBER 25, 1888.

GAS-WORKS AT CHRISTMAS TIME.

THIS is Christmas Day; and we hope that the appearance of the JOURNAL with its load of technical matter at our readers' residences on this day of feasting and family gatherings will not be regarded as unwelcome. The great festival, which is also the culminating point of the gas manufacturer's busy season, has been approached this year through a long spell of what is commonly called open weather. In London, however, there have been during the past week some sharp frosts, attended by fogs more widely diffused than dense. The darkness has, notwithstanding, been such that the drain upon the gasholders of the London Gas Companies was severe for days together; and it will not be surprising if it should turn out that the greatest known output of gas has already been recorded for this winter. In some years the maximum gas production falls before Christmas; and again, in other years, it comes well into January. So far as gas consumption is influenced by fog, the former should be the rule, because the atmosphere is usually more damp, and fogs are accordingly more frequent, before than after Christmas. It may be commonly observed, however, that there are very few really cold days when in a large town there is not also a marked thickness of the air, which induces

the residents to burn gas all day long. In this country very cold weather, attended by wind sufficiently brisk to keep the air of towns clear, is decidedly uncommon. Consequently the smoke of multitudinous chimneys falls down upon the housetops and streets as soon as it has become sufficiently chilled; and therefore the sharp "seasonable" weather which is so enjoyable outside the town presents a very different aspect among the houses in which gas is burnt. The responsibilities of the gas manager at this time of the year are heavier than are commonly recognized by the rest of the community. He knows, by bitter experience, that if, in the course of the past season of repairs, reconstructions, and extensions, his men have slurred over any portion of their work, now is the time when the effect is most likely to manifest itself. The Nemesis of inconsiderate design is also at his elbow; and the merest trifle of imperfect forethought, which would not trouble the perpetrator in a whole lifetime of summer work, is likely to make gigantic mischief during the short, dark days and long nights of December. Even when the manager has a works entirely to his mind, with ample carbonizing, purifying, storing, and distributing plant, there may be a breakdown at any moment in consequence of something that was done or not done during the summer and autumn. Such a man is at ease, however, in comparison with the poor wretch who knows that his holders are shaky, his purifiers too small, the connections in the yard involved and insufficient, or the retort-house badly equipped. There are few managers who cannot recall their own experience of such circumstances, when they spent days in vigilance over the pressures in different parts of the works, and nights in watching holders running down all too quickly for the gas-making power of the benches. Trials of this description are good for young managers, especially if they happen to have come out of large and well-appointed works, where there is enough and to spare of everything. A little of this sort of thing goes a very long way, however; and such anxieties are more pleasant to talk about afterwards than to endure at the time.

There should not, of course, be any difficulty now-a-days in properly equipping a British gas-works with plant and apparatus that can be depended upon to carry the undertaking through the Christmas pressure of work, without causing the Manager to lose his rest. Things were very different in bygone times, when struggling concerns, chronically short of money, could only be kept going at such seasons by dint of make-shifts and stop-gaps, which would startle out of his composure any staid student of gas engineering in these prosperous times. Then, an examiner in gas manufactures, if there had been such a personage, who wished to ascertain the real capacity of his candidates, would have put some such question as the following in the middle of his paper: "It is 8 o'clock on an evening in Christmas week, with a late market. Your last holder is running out at the rate of two sheets an hour, besides the make; and there are only five sheets left. Your ordinary night pressure has already been cut down to the finest margin which your experience tells you will keep a light in the low-lying parts of the district; and you have been working four-hour charges all day, in the endeavour to get up stock, until the heats are suffering. How would you suggest that the holder can be kept off the ground until the lights are slackened off from 11.30 to midnight?" There was not much time for study of the higher developments of gas engineering during these crises of the industry. Money for permanent extensions was only to be raised with extreme difficulty. The Manager had to go on his knees to his Board for a new holder; and when he did get it, it was often too small. As for mains, purifiers, condensers, and such like smaller matters, he had often to do the best he could out of the resources of the works; and these were bare enough. Yet amid all these distractions, the art of gas making did advance—slowly, perhaps; but yet generally in the right direction. The Manager who half-poisoned his customers with unpurified gas, through a break-down one Christmas, was prepared against a similar mishap the following year. The main that suddenly got blocked with naphthalene, or waterlogged, was put out of danger somehow. Holders were increased in size, retort-houses became airier and loftier, and retort-settings more efficient, until after a time impecuniosity and its consequences gave place to ease and comparative luxury. There was no royal road to successful gas making. The old gas companies got hold of a district somehow, and did their best to light it. They incurred all sorts of troubles and hindrances, made an infinity of blunders, became great nuisances in many ways; but came to affluence at last by dint

of dogged perseverance. The most interesting pieces of the history of gas companies, and the most striking reminiscences of individual engineers, are concerned with these days of struggle and trial.

Let us hope that none of the readers of these lines are in such a case, either at home or abroad. The best we can wish them at this season is plenty of work, and of means to work to good advantage. A gas-works is never so interesting as at this time, with every corner occupied; men swarming in every retort-house and workshop; steam-engines going at their best pace; and the coke-yard like an ant-hill for tippers and dealers. At other times there is much idle plant in a gas-works; unused retort-houses echo to the tread of the visitor; and furnaces seem to glare coldly at him out of their rusty doors and sight-holes. There is no scene so truly desolate as an idle workshop. In the depth of winter all is changed; and the visitor who only saw a gas-works in summer would hardly recognize it at Christmas as the same place. Let him look into a large gas-making station after dark on a raw, sleety December evening; and he will see such a scene of warm, cheerful labour as will not be easily forgotten. There are no sickly-looking factory hands here; and no stuffy, poisonous interiors. The men are all strong, hardy representatives of Labour under severe, but healthy conditions; and whatever may be the state of trade outside, these wiry stokers know they will receive good pay for their work. And as for their chiefs? Well, we cannot conclude this article without remarking, for the benefit of all whom it may concern, that the gas manager is deserving of the best consideration from his superiors, whether Directors of a Company or members of a Public Authority. As Christmas Day succeeds Christmas Day, the volume of his work swells. He has more work to do; more responsibility; more men to look after; greater anxieties to bear. It is only common justice that he should also feel that these consequences of increased business are attended with others to compensate for them; and that better pay and heightened respect from his employers should render him more solicitous for their interest as the opportunities for displaying it are multiplied.

RESIGNATIONS OF THE PRESIDENT AND SECRETARY OF THE GAS INSTITUTE.

THE letter which will be found in another column, in which Mr. Henry Woodall announces his resignation of the office of President of The Gas Institute, is a striking response to our last week's observations upon the condition of the Institute and Mr. Woodall's responsibility in connection therewith. The importance of this action on the part of the President does not require to be accented by any comment of ours; and it is not our intention to prophesy respecting its effect, except to remark that it will in all probability decide those members who have delayed severing their connection with the Institute at Mr. Woodall's request. Now that he has given up in despair, there is nothing to induce any members outside a narrow and local circle to remain. It may be gathered from Mr. Woodall's letter that he has met with something like concerted and insurmountable opposition from one particular group of Members of Council, and being unable through the retirement of others to overcome it, he has relieved himself from an untenable position by leaving his opponents to their own devices. Nobody who knows how proud Mr. Woodall was of his elevation to the presidency of The Gas Institute when he rightly esteemed it as representing the gas industry of the United Kingdom, and even more, will withhold sympathy from him in this disappointment. Ultra-sanguine as is his temperament, affairs must indeed be hopeless for him to quit his post. The terms in which he communicates his decision to his *quondam* colleagues, and through the mediumship of the JOURNAL to the general body of members, are explicit, and unfortunately leave no room for doubt as to the predisposing cause of his retirement. We do not believe that it is the wish of any one District Association to dictate terms to the rest of the country; but Mr. Woodall certainly allows it to be inferred that the disproportionately numerous group of members of the Manchester District Institution who for some time past have constituted the majority of the Council of the Institute, have made excessive use of their accidental power. From what we know of the generality of the Manchester men, we decline to think that they will thank their temporary representatives for precipitating this crisis. Mr. Woodall's allusion to the possible formation of a union of gas engineers belonging to the Southern

counties is not to be passed over lightly, though we sincerely hope, for the sake of the reputation of our northern friends, that there will not be any occasion to blame them for causing any such deplorable split in the fellowship of what has hitherto been a united national industry. Whatever happens, however, we are firmly persuaded that Mr. Woodall has acted throughout as the honourable gentleman he is, and that where he has failed, no other man could have hoped to succeed; for his character is sufficient guarantee that he has done the best that was possible with most unfortunate circumstances.

Mr. W. H. Bennett, the Secretary of the Institute, has also resigned. That Mr. Bennett's long and honourable connection with the Associated Gas Managers of the United Kingdom should terminate under such circumstances is greatly to be regretted; but this is only one, although an extremely unpleasant, incident in a course of misfortunes that have brought a once united and prosperous organization to the imminent brink of ruin.

COLLAPSE OF THE CHARGE AGAINST MR. W. CARR.

MR. WILLIAM CARR, late Manager of the Halifax Corporation Gas-Works, was arraigned on Tuesday last before Mr. Baron Pollock, at the Leeds Assizes, upon the charge of having mutilated one of the books belonging to the Corporation, to which he had access in his official capacity, with intent to defraud. The charge was made by the Corporation, after full deliberation, as the outcome of all that agitation, plotting, and counter-plotting, known to our readers as the "Halifax Gas Scandal." They chose their ground, and prosecuted their action with zeal that can hardly be distinguished from virulence; and the result is a crushing and ignominious defeat. The Judge allowed Counsel for the prosecutors every liberty, permitting him to drag in allusions, references, and insinuations which appear outrageous when compared with the strictness with which the issue between the Crown and the prisoner is limited in ordinary cases; and in the end his Lordship declared that there was no case to go to the jury. Mr. Carr was therefore discharged from custody in the most satisfactory style that his best friends could have desired. The prosecution broke down from sheer weakness, as we have all along suspected that it would, unless fresh matter could be imported into the case. As it was presented to the Magistrates, the case against Mr. Carr was absurdly slight; but there was just enough *prima facie* justification for it to warrant the Bench in committing the accused for trial, although we shrewdly doubt that they would have done so if it had not been for the excitement that had been got up in the neighbourhood on the gas-works question. Mr. Carr is to be heartily congratulated upon the way in which the matter has ended; although, of course, no triumph of the kind can make amends for the undeserved suffering and shame that he has had to endure from the hare-brained action of his old employers. Now that the personal question affecting Mr. Carr has been settled, it remains to be seen what the Corporation will do next. The Mayor has talked very big about his determination to probe the matter of the gas-works administration to the bottom, and it remains for him to make good his boast. For the present, it must be said that the cause of the Corporation looks distinctly worse in the light of this *jiasco* at the Leeds Assizes.

THE COUNTY COUNCIL ELECTIONS.

It is gratifying to observe that in very many instances the candidates for election to the new County Councils are men of standing and repute, in whom the county ratepayers may place full confidence. Notwithstanding the efforts that are being made in some localities to turn the forthcoming elections into trials of party strength, there is a general feeling that character and position are of more account than political colour. Numbers—perhaps the majority—of the candidates are gentlemen either holding the Commission of the Peace or are of the order from whose ranks the Commission is ordinarily filled; so that there is good promise that the tradition of county government will not be altogether broken by the introduction of the elective element. It is really a small matter whether men in authority are nominated from above or elected from below, so long as they are the right men for the duties reposed in them. To hold that any special sanctity attaches to the method of selection would be sheer pedantry. People who read their newspapers with intelligence must learn that neither public virtue nor corruption belong exclusively to any particular system of government. With regard to the selection of County Councillors, the great thing is, as we have already

remarked, to choose men who are capable of rendering the community good service, and who will be above the influences that have made the name of the Metropolitan Board of Works so abhorrent to Londoners. It is only what might have been expected that certain members of the dying Board should try to renew the possibilities which some of them have used so cleverly, by seeking election to the London County Council; but public opinion is dead against them. Newspapers of the most diverse political views unite for once in protesting against the reappearance of the discredited Board of Works elements in the thin disguise provided by the Local Government Act. All agree that the Board of Works must be wiped out, and its constituents relegated to that obscurity from which they should never have emerged. They have had their day; and must now give place to men with cleaner characters. If, as is generally supposed, the question of the water supply of the Metropolis is to occupy the attention of the London County Council, perhaps to be followed in due time by the consideration of the gas supply, men of the most irreproachable integrity, as well as of signal ability, will be needed for dealing with these great matters; and it cannot be said that the Metropolitan Board is rich in members with either of these qualifications.

THE CIRCULAR INQUIRY NUISANCE AGAIN.

THE circular inquiry nuisance is very hard to kill. From time to time we have evidence that our exposures of the practice have discredited it in some places; but it breaks out again elsewhere. From this we conclude that offenders in this way are mainly to be found among people who either never see the JOURNAL, or are too lazy to study it. This view is strengthened by the observation that most of the inquiries with which the culprits plague their correspondents concern matters that intelligent readers can learn all about from our columns; and the remainder are usually of a more or less impertinent character, such as only very ignorant and uncivilized individuals would think of putting to perfect strangers. We have recently seen a remarkable example of the circular inquiry, emanating from a Clerk to a Local Board, who wants to learn something about the administration of gas-works without paying for the advice of a duly qualified engineer. He does not even trouble to ascertain the names of those whom he favours with his attention; but merely addresses his letter to "The Manager of the Gas-Works," and says: "Will you please answer me queries on other 'side hereof,' without unbending so far as to say he will feel obliged by the complaisance of his unknown correspondents. The queries thus flung at the heads of humble gas managers contain, among others, questions as to whether the recipient makes plans and superintends the outlay of new capital, and whether he is allowed a house, fire, and lights. This sort of thing is nothing less than sheer impudence; and the questioned gas managers must have been extraordinarily meek or good-tempered who did not instantly consign the impertinent communication to the waste-paper basket. Men who reply to inquiries of this order have only themselves to thank when they find the same weapon employed to their own detriment; they, in short, "make a rod for their own backs." We have before us another letter of the same class, which although commendably impersonal in its purpose, yet offends by begging for information from strangers to be used for the writer's guidance. We have repeatedly stated in general terms the conditions under which ordinary inquiries may be circulated without offence; but the addressing of these communications to strangers places the interrogator under such a marked, though vague obligation to people whom he can never hope to repay, that men of any delicacy of feeling will shrink from taking the step which to many seems so easy that they rush out their inquiries as though everybody lay under an ordinance to pour out their stores of information to the first comer who chooses to intrude upon them by virtue of the postman's introduction.

MANY of our readers who remember Mr. Henry Hughes, formerly of the Plough Bridge Tar-Works, Rotherhithe, will regret to learn of his death on Sunday, the 16th inst. The deceased gentleman was in his 80th year.

THE course of lectures on cooking by gas, which, as announced in our last issue, Madame Altling-Mees is delivering in Brussels, is, we learn, meeting with rich success. On Monday last week, Madame Altling-Mees had a large and select audience in the new hall of the Gaziers Belges; and she then maintained her high reputation as a demonstrator of the use to which gas can be put in culinary operations by cooking, with a No. 6 (old) Fletcher stove, an entire dinner in one hour.

THE AFFAIRS OF THE GAS INSTITUTE.

RESIGNATIONS OF THE PRESIDENT AND SECRETARY.

By Mr. Henry Woodall's desire, we publish the following letter, which he has addressed to the Council of The Gas Institute:—

Leamington, Dec. 20, 1888.

To the Council of The Gas Institute.

Gentlemen,—It is with very great reluctance that I have permitted myself to be brought to the conclusion that I must relinquish the honoured position of President.

I had felt from my earliest experience in the chair that the secession of so many respected members from the Council had robbed us of much of our representative character. Still, there were at least three districts represented. The subsequent retirement of Mr. Colson accentuated the difficulty; and now I learn to-day that Messrs. Cross and Peaty have also resigned. Of the eight members who remain, one is too far removed to be able to attend our meetings, and especially at this time of the year; and five are members of the Manchester District Association. I feel that, however desirous the latter may be to pursue their duty in an impartial spirit, it is almost impossible for them to realize the feelings of other sections of the members, with whom they have necessarily but limited opportunities of associating. It was on that account that, at our last meeting, I urged the desirability of calling a special meeting of the members, to discuss the two policies which had occupied the consideration of the Council.

I have urged, and I continue to maintain, that unless the voice of the body of members is taken, the inevitable result will be that another Association will be formed, which will attract the great majority of our profession south of the Northern Counties; and that the title of the Institute, and its properties, will become the possession of a section only of our numbers. This I am deeply persuaded would be a very great misfortune. The old feeling of fellowship, which used to be as wide as the world itself, will be narrowed and broken; and it will be remarkable indeed if unworthy jealousies do not take its place.

An Institute which is not representative, can scarcely be an Institute at all. At any rate, it was not such an Institute which elected me to office, nor is it such an one that I can consent to serve; and as I have failed in my attempt to re-establish a representative body, I can no longer have either pleasure or pride in office.

It pains me much to think that by the course I am taking, I am aggravating the troubles which were too embarrassing before; but I can only hope that you may speedily arrive at a happy solution of them, and win the approbation which I had hoped to share with you.

I am, Gentlemen, Yours faithfully,
HENRY WOODALL.

We have also received from Mr. W. H. Bennett the following copy of the communication by which his resignation of the office of Secretary of the Institute will be made known to the members:—

Dear Sir,—I have this day presented a letter to the Council of The Gas Institute, of which the following is a copy:—

To the Council of The Gas Institute.

Gentlemen,—I beg to tender my resignation of the appointment I now hold as Secretary of The Gas Institute, and shall be obliged by being relieved from my duties as soon as possible.—Yours faithfully, W. H. Bennett.

It is with very great regret that I have felt compelled, in justice to myself, to take this step; but as the members generally are not in my opinion fairly represented on the Council—more especially now that the President has resigned, and as the course being pursued by those attending the Council does not appear likely to result in a fair representation for a very considerable time to come, I feel that it would not be honest towards the members to continue to assist in promoting a policy which can only be attended by disaster, and the ultimate wreck of the Institute.

I, therefore, beg to offer to the members my thanks for the confidence reposed in me, and so often publicly expressed, during the last twenty years, and say that I trust the gas profession may not long be without a representative Institution worthy of it.

Yours truly, W. H. BENNETT.

MR. R. C. SMITH, a member of the Bridgnorth Town Council, has been appointed honorary gas examiner for the town.

THE Secretaryship of the Board of Trade (in succession to the Earl of Onslow) has been accepted by Lord Balfour of Burleigh.

MR. JOHN WOODWARD has, we learn, for the present been placed by the Manchester Gas Committee in charge of the Bradford Road Gas-Works.

AMONG the notices on the paper for discussion in the next session of Parliament are two in which our readers are interested. One is by Mr. Craig Sellar, who intends to "call attention to the report of the Joint Committee of the two Houses of Parliament on the subject of Private Bill Legislation, and to move a resolution, urging the Government to legislate upon the subject;" and the other is by Mr. Seager Hunt, who purposes introducing a Bill "to consolidate the Acts relating to the water supply of London."

Essays, Commentaries, and Reviews.

GAS AND WATER COMPANIES IN THE STOCK MARKET.

(For Stock and Share List, see p. 1120.)

BUSINESS on the Stock Exchange during the past week has not presented any feature of particular interest; and the markets generally have been rather quiet, as might be expected at the time of year. Dulness was the prevailing tendency at first—the Panama Canal affairs being regarded as likely to upset the Paris Bourse, while there was some apprehension that the Suakim Expedition would bring trouble at home. Later on, however, as the position of the Money Market appeared more satisfactory, a better tendency set in; and there was more strength all round. Still, movements are very slight, and the course of business has not been very interesting. The Gas department has been quiet, and fairly firm. Business has not been abundant; and but few stocks have been dealt in. Gaslight "A" has had its fair share of transactions, and has been very steady—marking much about the same prices every day. The preference and debenture stocks have not been touched; but, of the latter, the 6 per cents. have been put down 2 in quotation. This is a sort of reconsideration of the *ex div.* quotation which had put them up 3; and consequently they still stand 1 to the good. South Metropolitan has been quieter. The "A" is steady; but the "B" is still weak, and has fallen back 1. Commercial continues inactive; a single transaction in the old stock being all the business marked. The Suburban and Provincial Companies offer little for remark. Brentford old has changed hands once or twice at good figures; and one of the rare transactions in Crystal Palace confirms, by its price, some of the figures realized at the recent sale at the Mart. The Foreign undertakings show the only advances in quotation which have been effected in the week. Continental Union has made a further rise, although no business has actually been recorded in it; and Australian (Sydney) debentures, which are now creeping up towards the level of Melbourne, have advanced 1. Of Water, there is little to be said. The tendency on the whole is not quite so good, except in Lambeths. The rest have been done at rather low figures; but none have actually receded in point of quotation, with the exception of South-wark ordinary, off the high *ex div.* quotation of which 2 have been deducted.

The daily operations were: Gas business on Monday was mostly in Gaslight "A," at good middle figures. Of the rest, Brentford old was most conspicuous. The only changes were a rise of 1 in Continental Union fully paid; and $\frac{1}{2}$ in the partly paid. A little was done in Water; but prices were not grand. Business in Gas was rather more slack on Tuesday, principally in the Foreign undertakings; and prices were only moderate. Water was about the same as before. On Wednesday, Gas was very quiet, and offered nothing to remark. The few transactions marked in Water were at very moderate figures. On Thursday, business was again very limited. South Metropolitan "B" were weak; and prices generally were only moderate, except for Australian, which rose 1. Water was dull. On Friday, the only business was in the Metropolitan Companies. Gaslight "A" was pretty firm; but South Metropolitan "B" fell 1. The only feature in Water was an advance of 2 in Lambeth 10 per cents.

ELECTRIC LIGHTING MEMORANDA.

ELECTRIC LIGHT QUESTIONS IN PARLIAMENT—THE AFFAIRS OF WOODHOUSE AND RAWSON, LIMITED—THE DANGER OF OVERHEAD WIRES.

THE subject of electric lighting was among the last things brought under the notice of the House of Commons before the prorogation. On Thursday, Mr. Watt asked the President of the Board of Trade whether the Electric Lighting Act precludes the grant of Licenses to more than one undertaker for the same area, whether the Act prevents the breaking up of streets without the consent of the Board of Trade, whether inquiry is made as to the responsibility of undertakers before Licenses are granted, and whether any Licenses had been abandoned in consequence of the heavy cost of obtaining them in face of the opposition of local authorities. One cannot help thinking that questions of this kind would be answered just as well if addressed to the Editor of a technical newspaper as when put to the head of a Government Department. Sir M. Hicks Beach dealt with his questioner categorically; the answer to the first query being in the negative, to the second in the affirmative, to the third the same, and as to the last the Department has no information. After this elementary exercise, Sir Henry Roscoe more usefully engaged the Minister's attention by pointing out the fact that four Electric Light Companies have given formal notice of their intention to make application for statutory privilege to supply electricity in the same district of Kensington, and asking whether the Board of Trade could prevent the objectionable consequence of such competition as regards the breaking up of roadways without waiting for the action of the local authority. To this very apposite reminder of the evils of competition in such matters, the President of the Board of Trade gave a satisfactory answer. A further point was made by Sir George Campbell, who asked Sir M. Hicks Beach to take care that no Licenses or Provisional Orders were granted, except to undertakers who could give substantial guarantees of their ability and willingness to carry out the proposed work. Altogether the putting of these questions—especially Sir H. Roscoe's—served a very good purpose. It brought before Parliament and the public the fact that London

is threatened with competitive electric lighting, which can only be prevented by the exercise of vigilant wisdom by the Board of Trade. We showed last week that it is not sufficient to invoke the activity of local authorities in this emergency. These are for the most part quite ignorant of the true working of competition in matters of this kind, and their instruction would be too dearly purchased at the cost of delivering London over to the tender mercies of the horde of electric light speculators.

An extraordinary general meeting of the shareholders in Woodhouse and Rawson, Limited, has just been held, ostensibly for the purpose of confirming the appointment of Auditors, but really, as it appears, in order that the Chairman might have an opportunity of advertizing the recent progress of the Company's business. At any rate, he improved the occasion by reciting the lighting and other contracts completed and entered into by the Directors since the last ordinary meeting, with the intention of impressing the shareholders and the outer world with a due sense of the value of their property. It is truly remarkable how these electrical concerns ramify. Now we make bold to say that the vast majority of people who hear of Woodhouse and Rawson, Limited, never think of the possible subdivisions of the concern. Yet in the Chairman's speech at the meeting in question, we find allusions to "our subsidiary Company working in Yorkshire;" to the "Woodhouse and Rawson Electric Supply Company of Great Britain, Limited, one of our subsidiary companies which does a merchant's business in buying and selling electrical goods;" and another concern called "the Woodhouse and Rawson Electric Manufacturing Company." Besides this, there is to be a new Company formed to do something in the way of dealing in shares which the original Company cannot legally do; and there are promises of great things in the way of amalgamations with other Companies yet unnamed. This may be all right and proper; but to the unsophisticated spectator, it looks rather too much like attempting to multiply scrip which may be negotiable from bearing a name generally understood to belong to a successful concern. It is the most unpleasant thing we have ever noticed in connection with the administration of the business founded by Messrs. Woodhouse and Rawson.

It is well understood that the Grosvenor Gallery Electric Light Company, and two or three other concerns in the same way of business, are at the present time carrying on their operations in different parts of London by what may almost be called the surreptitious running of wires from their generating stations over the house tops to the premises of their subscribers. Seeing the maze of telegraph and telephone wires which occupy the same "coign of vantage," above the crowded streets, we have repeatedly remarked on the hazard attending this method of distributing strong electrical currents, which, moreover, practically sets at naught the provisions of the Electric Lighting Act for the protection of the public. The practice has grown from small beginnings, until we believe that now there are many arc lamps in use by advertising shopkeepers the current for which—quite strong enough to kill a man, or set fire to a house—is brought by means of wires carried over the tops of houses by the most audacious trespass. It is all very satisfactory to the parties primarily interested, so long as there is no disaster; but the first catastrophe which brings the system under the notice of a coroner's jury will be the signal for its collapse. That such an eventuality is by no means improbable may be gathered from the complaint of a firm of solicitors recently published in a daily newspaper, whose telephone connections were attacked and fused by some agency which they believe to have been accidental contact with an electric light wire. It must have been either this or a flash of lightning; and the latter is inadmissible. Therefore although the complainants wisely disclaim any wish to be regarded as alarmists, they made their case known, in order that the danger in question may be guarded against by the only satisfactory expedient of burying all electric light wires out of the way of telephonic connections. Nothing will be done, however, until somebody is killed outright.

PROHIBITING THE USE OF SACCHARINE IN FRANCE.—The following (says *Industries*) is an abstract of the preamble of the Bill now before the French Chamber, prohibiting the importation of saccharine into France:—"The attention of the Administration has been directed to a new coal-tar product known as saccharine. This substance, which differs essentially in its elementary composition from vegetable sugars, possesses much greater sweetening power, a quality that was sure to lead to its being used as a substitute for sugar in many cases. We learned from our Consular agencies abroad that factories were being established in certain countries for the purpose of bringing saccharine into competition with beet and cane sugar; not only in France, but also in other neighbouring markets. The high cost of that substance seemed to constitute an insuperable obstacle to its general adoption; but lately the situation has changed. It can now be more cheaply produced; and already it is extensively used, mixed with glucose, in the preparation of jams, syrups, and liqueurs. It has, therefore, become an urgent necessity to provide a remedy for the evil, in the interests of the Customs receipts and that of the health of the consumer; for it has been shown by the report of Drs. Bronardel, Poucliet, and Ogier, in the name of the Consulting Committee of Hygiene, that saccharine, and the various preparations derived from it, are noxious to health, and ought to be prohibited. Wherefore the Government has deemed it expedient to prohibit the importation of saccharine and saccharinated substances."

MR. DIBDIN ON STANDARDS OF LIGHT.

ALTHOUGH the paper read by Mr. Dibdin at the Society of Arts on Wednesday last was rather a *résumé* of his conclusions on this subject, as already set forth in the reports presented to the Metropolitan Board of Works, in papers read at meetings of The Gas Institute and the Society of Chemical Industry, than a further advancement in respect to this abstruse subject, still it resulted in bringing out one or two new ideas from the reader of the paper, and from Mr. Alexander Siemens and Mr. Williams in the course of the subsequent discussion. Most of our readers must be well aware that Mr. Dibdin objects to candles and to the amyl-acetate lamp as being altogether unsuitable for light standards; that he is more hopeful as regards the "slit" or "screen" as applied in conjunction with carburetted air-gas; and that he considers the Harcourt pentane standard the most suitable of all; also that he has conducted a very elaborate series of experiments in connection with the subject. Anything that he has to say about standards of light is, therefore, worthy of attentive consideration, as coming from an undoubted authority.

Mr. Dibdin commenced his paper on Wednesday by showing the importance of the subject, as illustrated by the amount of money annually expended in London for gas. But this is rather an argument for the necessity of using the best obtainable burners that will develop the highest possible duty from the gas, than for accurate testing, which will never actually save the public money. The value of the gas may be determined to within a fraction per cent., but, unless the public are educated to use better burners, the matter will not affect them; and they will always prefer to form their own opinion as to the value of gas or any other source of light, irrespective of official tests. Gas engineers know well that an irate consumer, prejudiced against the gas by insufficient supply, or by the use of unsuitable burners, has very little respect for photometrical results; and at once sweeps away any argument as to proved candle power with a Pecksniffian flourish of the right arm. The parties who are really most interested in accurate, unvariable testing are the gas companies, who occasionally are subjected to some injustice on account of the vagaries of the candle, or—and we say it with all respect—the vagaries of the gas examiner. The long list given by Mr. Dibdin of attempts to improve upon the sperm candle, and the fact that it is not yet displaced, renders it an open question whether many of the defects ascribed to it are not also common to any source of light. On the question of purity of material, for example, it came out in the course of the evening that the amyl-acetate used for the lamp to which that title has been given must be perfectly pure, if reliable results are to be obtained. If this is so with amyl-acetate, it may also be the case with pentane. The unsettled state of opinion amongst English photometrists is certainly somewhat behind the course pursued in Germany, where endeavours are being made to improve the candle and the amyl-acetate lamp, with a view of rendering them reliable standards.

As regards the colour of the amyl-acetate flame, on which Mr. Dibdin lays so much stress, it should be observed that no difference is perceptible to the eye between the colour of this flame and that of pentane. Both were exhibited side by side; and both gave, to the eyes of the audience, a clear, intense white light. Mr. Alexander Siemens observed that Mr. Dibdin had endeavoured to get a higher duty out of the lamp supplied to him than it was intended to yield, by increasing the height of the flame from 40 to 51 mm., in order to make the light equal to an English sperm candle; and perhaps this is the reason why the German operators seem to have a better opinion of this proposed standard than Mr. Dibdin. Mr. Williams spoke very highly of the amyl-acetate lamp; and, indeed, he appeared to think that, with a few simple improvements in detail—such as the substitution of a platinum wick-tube for the German silver one—it would prove a very useful apparatus. It certainly possesses the advantage of simplicity, portability, and cheapness. Bearing in mind that legal gas testing applies to large towns and also to small undertakings, having perhaps a capital of £4000 or £5000, these are important considerations.

Mr. Dibdin gave an account of the proposed molten platinum standards; but he had very little hope as to their practicability, and this was fully illustrated by the examples exhibited. The great objection to this principle is that it is of an evanescent character. The observation must be taken at the moment of best effect; just as the platinum is on the point of fusing. So that to obtain one reading, a number of trial observations must be made, and all but the highest rejected. The platinum unit requires a skilful operator at the sight-box, and another very carefully regulating the application of heat, which may be furnished either by oxyhydrogen or by electricity. In the first case the oxygen supply, and in the second the current of electricity, must be very gradually increased until the foil melts. The oxyhydrogen worked fairly well. Of the two electric-platinum units exhibited, one required an unparliamentary amount of coaxing to get it to act; and the other one was not in working order. It seems idle, therefore, even to mention molten platinum as a possible standard.

Mr. Dibdin admits that "it would probably not be difficult to formulate a manner of using the candles that would do away with many of the objections and variations found in the course of his experiments; and in this respect he was supported by Mr. Williams. But while in England photometrists are talking about the possibility of regulating the composition, and the number of threads to the wick, in Germany they are actually trying to carry it out, by making the candles much shorter, so as to get a better centring of the wick, &c. Indeed it is evident that there is too

much of what may be called 'red-tapeism' in connection with English photometry. It is simply absurd to suppose that, because the Acts of Parliament specify "sperm candles of six to the pound, burning 120 grains per hour," anything that can be compressed into these conditions will do; and that the examiner has no option even if "they are shut up in a box with insufficient ventilation," or if the wick curls up like a cork-screw or a pig's tail. The Act of Parliament certainly does not provide for these contingencies; but it is only consistent with common sense to suppose that in the first case the apparatus should be properly ventilated, and that in the second a proper candle should be substituted. Whatever may be the letter, it certainly cannot be the sense of the Act that the examiner should knowingly use a candle that is unjust either to the gas or to the consumer. Whether candles or any other standard may be used, the skill and experience of the operator must always be a factor in the experiment.

The author devoted some time to a criticism of the statements made by Messrs. Heisch and Hartley, in their report to The Gas Institute in 1884, as to the unsteadiness of the pentane flame; but the specimen exhibited on the platform rather supported the views expressed by those gentlemen than otherwise. No special draught was observable in the room; but it wavered considerably until protected by an Argand chimney glass. Mr. Dibdin recommended the use of the chimney and cover in all practical work. With respect to chimneys, Mr. Williams raised an important point. He had found that even the best glass chimneys were liable to differences of refraction, and the presence of striæ; so that a different result might be obtained by partially rotating the chimney so as to bring a different part of its surface before the flame. If this is applicable in connection with pentane, it is pertinent to ask what the effect of the Argand chimney, as invariably used with the gas-flame, may be. Mr. King has found that a clear glass globe obstructs 10½ per cent. of light; Mr. Wood puts it at 12 per cent.; while Mr. Storer finds that flat sheets of various kinds of glass have an obstructive effect ranging from 6 to 13 per cent.* In order to overcome this defect, Mr. Williams has tried experiments with plates of thin mica, and has succeeded in obtaining a chimney that has no effect on the photometer. Whether off or on, the lighting effect is the same. According to the results above quoted, the effect of the Argand chimney must be to obstruct a considerable portion of light. It would, therefore, be interesting if Mr. Williams could adopt a similar thin mica chimney to the gas-flame and observe the result.

At the conclusion of his lecture, Mr. Dibdin exhibited examples of different forms of wicks taken in the course of burning, ranging from a stiff-backed upright wick to one curled down nearly to the shape of an O. Alterations in the shape of the wick, or divergencies due to inaccurate centring of it, are doubtless the weak point of the standard candle. Some time ago Mr. Sugg drew attention to this point, and illustrated it by means of a series of photographs, showing the deviation from the plumb-line that gradually took place.† His observations, however, extended over some 45 minutes; and the point of this question is, What extent of deviation would take place in the course of 10 minutes? If accurately adjusted at the beginning of the experiment, how far out of perpendicular would the flame draw over before the end? But besides differences due to the deviation from the perpendicular by the curving of the wick, there is the (as yet) undetermined point as to the effect of the shape of the wick as regards light-giving power. According to Mr. Dibdin, it appears that a straight wick, wholly enveloped in flame, gives less light per grain of sperm consumed than a bent wick with a glowing top. Here, again, Mr. Williams came to the rescue. He said that a skilled photometrist knew well what the proper curve of the wick should be. It should approximate to a parabolic curve.

Altogether, the result of this paper and the subsequent discussion is to show that the much-abused candle is not altogether a hopeless failure as a standard of light; and that, with the exercise of a very ordinary amount of common sense and skill—especially if combined with a few simple precautions on the part of the maker—much better results can be obtained with it than is at present supposed. Some additions to the existing legal conditions are evidently desirable; but whether, as Mr. Dibdin says, it would be as easy to introduce a new standard so as to obtain these is, of course, a matter of opinion.

THE FOURTH DRAWING OF THE SYDNEY GASHOLDER.—With the present number of the JOURNAL we give the fourth plate of the series illustrating the new holder for the Sydney Gas-Works; and, as explained last week, we defer any description of the details until the publication of the fifth drawing in next week's issue.

IMPROVED STREET LIGHTING AT LEITH.—A commencement has been made by the Corporation of Leith in improving the lighting of the public thoroughfares, by fitting the public lamps with governor burners, in accordance with the resolution recently passed by the Edinburgh and Leith Gas Commissioners. The lamps in Hermitage Place have been provided with Peebles's governor burners, consuming 2 cubic feet of gas per hour; and last Wednesday night were lighted for the first time since the change. The improvement in the lighting, it is stated, was very noticeable. At their meeting last week, the Gas Commissioners sanctioned the purchase of 2000 governor burners; and in a week or two all the lamps in the town will be fitted with them.

Technical Record.

MANCHESTER DISTRICT INSTITUTION OF GAS ENGINEERS.

At the close of the discussion on Mr. Dalglish's paper (*ante*, pp. 1067-8) at the recent quarterly meeting of this Institution, the members proceeded to consider the paper read by Mr. Thomas Newbigging at the Doncaster meeting in August, entitled

GASHOLDERS WITHOUT UPPER GUIDE-FRAMING.

The PRESIDENT said they had now to discuss the paper read at the last meeting by Mr. Newbigging, on the subject of "Gasholders without Upper Guide-Framing." He was sorry Mr. Newbigging happened to be away; but he should ask Mr. W. Gadd to introduce the discussion by any additional observations he wished to make.

Mr. W. GADD (Manchester) said he was obliged to the President for calling upon him to introduce the subject. The model which he had brought was not the one seen at Doncaster. It was a larger one with three lifts, and would, he thought, be found a little more interesting than the old one. Since he last had the pleasure of addressing them at Doncaster, he had been engaged upon a great number of experiments with regard to the principle involved in the construction of a gasholder on this system. As they were well aware, there had been considerable discussion on the subject since the paper was read; and it was highly probable that there would be much more discussion until the invention was properly demonstrated. It was his desire to bring the demonstration to the issue; and he had very good reasons for believing that it would not be long before they would have the pleasure of seeing and examining for themselves an actual working holder on this plan. This would set the matter at rest once for all, whether a holder was safe under such conditions. The experiments he had made, instead of contributing in any way to cast doubt on the stability of a holder on this method of construction, had added, he was going to say, almost infinitely to his faith and belief in the final results and success of a holder constructed in this manner. In his paper, Mr. Newbigging said that, as at present constructed and guided, gasholders were capable of resisting the maximum crushing strain that was exerted by the greatest wind pressure upon their exposed side—*i.e.*, a pressure equal to 20 lbs. to the square foot exerted upon a plane represented by 50 per cent. of the area of vertical transverse section of the holder. Well, he thought he would submit the model to an actual strain to try what it would stand. He took the model they saw at Doncaster, and submitted it to an actual strain—not to any supposed reduced strain—of 20 lbs. to the square foot exerted on a plane represented by 50 per cent. of the area of vertical transverse section of the holder. That pressure of 20 lbs. to the square foot took no effect whatever upon the model. He doubled it, and again it took no effect; and he determined to increase the strain until he ruptured the model, or gave it a permanent set-over. He kept on increasing the strain, and both he and Mr. Wilson, who assisted him, were surprised at what took place. They weighted it until they did give it a slight permanent set-over; but it affected it so little that, when the force was removed, the model would work, though imperfectly. The exact force necessary to bring it to the point of injury was a force of 648 lbs. to the square foot. Mr. Newbigging gave 20 lbs. to the square foot as the greatest wind pressure; but it actually required 648 lbs. to the square foot on that little delicate model to give it a permanent set-over in the way of injury—nothing short of that did it. This, he was bound to say, somewhat startled him. He had not expected it would stand so much; and he found it necessary to seek for an explanation of the cause of this resistance. The model, he wished to explain, was simply a cylinder of ordinary thin tin, with a tin top. He was not going to say that this represented exactly the comparative strength of a large holder. The model might be a little stronger, in proportion, than the large holder, because although it had no upright standards whatever round it, still the thickness of the tin might be said to be greater than the sheets would be, in proportion, in the large holder, and this would compensate for the absence of the upright supports. He was free to admit that it might be stronger in proportion; but see the difference! There was a difference in the increased proportionate strength of 648 lbs. to 20 lbs.; yet the model was not this much stronger. It was impossible to conceive of its being anything like so much stronger. Suppose they assumed it to be double the strength—that was 40 lbs. to the square foot; but, instead of that, the model required a strain of 648 lbs. to cause it to set-over. There was therefore something in addition to the construction which had to be investigated; and he determined to inquire into it. They had, no doubt, all read the able articles on the subject of gasholder construction in the JOURNAL OF GAS LIGHTING. He was pleased to contribute his little meed of admiration of those articles, which were very carefully written, and were upon the acknowledged and admitted lines of mechanical construction. But there was a form of structure which, so far as he knew, had not been very carefully examined. It was true that it was many years since he consulted the text-books, and he was speaking from memory; but he did not recollect that Rankine or any of the other authorities had investigated this point, though he had a hazy notion that a French writer had treated of it. However, it was so difficult that he determined to investigate it *de novo*. If they took a base, which might be represented by the bottom curb of the holder, and fixed thereon (say) four upright beams, joined rigidly

at the base, they had a system of cantilevers. The force required to bend one, multiplied by the number would equal the force required to bend the four; but if these cantilevers were joined at the top by another rigid bar, which might be represented by the cup rings of the holder, the actual force exerted transversely would be four times what was required in the first example. The reason of this was that two bends in opposite directions of each upright member took place when they were joined top and bottom; whereas, when they were unconnected at the top, as in the first example, there was only one bend. This accounted for double the force being required. But, as these two bends were in opposite directions, they had to be made about a neutral axis lying midway between the two horizontal members. This halved the length of leverage at which the force took place; and this again multiplied the resistance by two, which accounted for four times its strength in resisting strains. If they had the upright from a bottom curb standing up, and they should then be joined by a rigid ring at the top, the resistance to the overturning of these uprights was multiplied by four, by the rigid ring at the top. He thought it necessary to go into this, to give them the reason why a holder which was held rigidly at the base became very strong indeed. It had been suggested that a great deal of strength would require to be put into a holder built on the plan he proposed; but they would see that there was no reason why this should be necessary. Still, he had always admitted that, if it were necessary, it was easily done; and it would form an infinitesimal addition to the expense, when compared with what was swept away in the guide-framing. He wished to draw attention to the fact that the spiral motion was exceedingly slight. The screw or spiral was of what might be called the quickest possible description. The holder was a structure with an enormous base; and this base was held as firmly as though it rested on the ground. If they had such a structure resting on the ground, they could not conceive that any wind would blow it over. By his plan, the holder was in a really stable position. As long as the bottom curb kept in form, there was no possibility of any accident taking place; nor was there any possibility of jamming. It would not matter if they had 2 or 3 inches of play between the rollers; all that was necessary was for it to be on one set of rollers at one time. They had tried the model under all possible conditions.

The PRESIDENT said that, if he understood Mr. Gadd aright, in taking a pressure of 20 lbs. to the square foot, and applying it to one-half of the complete surface of the holder, they had what Mr. Newbigging considered a fairly heavy wind pressure; but that, in the case of the model in question, it stood a pressure of 648 lbs., as against the 20 lbs. It certainly seemed an enormous difference. One could not, however, help noticing that, in the structure as it was, having the frame of the holder inside, and with a grip on the guide-rails all round, if wind pressure came from one side, that side was held down, while the other side was held up. This was different to a holder with outside framing; inasmuch as in that the bulk of the strain was on the opposite side to that from which the wind came, while in this case it was distributed all round. It was an exceedingly ingenious arrangement. Whether Mr. Gadd was to get the credit for the invention, he did not know. He saw that Mr. Livesey had been reading a paper on the same subject, though he arrived at the same end in a different way. Mr. Gadd took a spiral frame all round the tank; while in Mr. Livesey's it went first one way and then another. Anyway, they had Mr. Gadd's paper before Mr. Livesey's, though both were based on the same line of thought.

Mr. HARRISON VEEVERS (Dukinfield) remarked that when Mr. Newbigging mentioned that he intended to read a paper on gasholder construction, he said it would rather surprise the gas world. It certainly astonished him more than he was led to expect. It certainly surprised him that such a total revolution in gasholder construction should be first brought out at a meeting of their Institution. He had not much opportunity at the last meeting of considering the subject; but, on reflection and studying the paper, he came to the same conclusion as the President, that the holder was fixed by the pressure of the rollers all round. Leaving the scientific part of the subject, he should like to say something as to its æsthetic aspect. Gasholders were not things of beauty. Designed and painted in any way they liked, they were not pleasant to look at. A holder constructed on Mr. Gadd's principle was, in his opinion, more a thing of beauty than if it had a number of sticks standing round it, pretending to hold it up. From this point of view alone, he was inclined to look with favour upon it.

Mr. N. MEIKLEJOHN (Longwood) said Mr. Gadd had shown them that a lever bound at both ends was four times as strong as one with one end free; but he did not gather that anything he said gave a reason for the extraordinary strength of his model. All holders were at present made, as the one proposed by Mr. Gadd was, with a top and bottom curb, and a space of intervening sheeting; and he should like to have heard Mr. Gadd explain the difference between the resisting strength of an ordinary holder and his model. The idea seemed to be that the fixing of the bottom curb would add the extra strength; but as it was to be a floating vessel, which would rise up and down, he had never yet been able to see how this rigidity was to be obtained. He did not for a moment deny that it was as Mr. Gadd represented it; but he had not been able to see how the fixing would add anything to the actual strain it would resist in case of wind pressure coming against the side of the holder. With Mr. Veevers, he thought the æsthetic point of view should not be lost sight of; but granting that the engineering

feat was possible, they ought to know something of the difference in cost. They were to have a total taking away of the guide-framing; but if the cost came anything near that of guide-framing, he should prefer to have the framing. The framing did add to its appearance; and it was certainly useful when the lutes froze and snow gathered on the top. With the holder as it was in the model, it would be a rather difficult thing for a man to go up and clear the ice out of the cups or the snow off the top. There might be a spiral framing for these purposes; but at present the framing answered the purpose, as well as resisting the over-turning pressure of the wind. If the difference in the cost of the two structures was not large, he should certainly prefer to still put up the guide-framing.

Mr. W. W. HUTCHINSON (Barnsley) wished to know how long the actual holder on this plan, to which Mr. Gadd referred, had been erected; and if it had stood the test of any strong winds.

Mr. GADD explained that the holder was not yet erected, but was in contemplation.

Mr. J. DALGLIESH (Glossop) asked if Mr. Gadd could give some idea of the difference in cost of the two arrangements. He had some sympathy with the view expressed by a previous speaker; and if the cost was not very much lower, it would certainly, as far as his experience went, be better to stick to the old form. At the same time he admitted that the new invention gave a perfectly rigid structure. Could they not combine the two things, and have a light framing round a holder on Mr. Gadd's principle? They ought, however, to have some information as to the cost, so that they might be better able to form an opinion. There would certainly be some difficulty in getting to the top of Mr. Gadd's holder without some arrangement like a spiral staircase.

Mr. BALL said he should like to ask just one question. As the framing was to be done away with, the strain it was called upon to bear would have to be taken up somewhere else; and it seemed to him it would be taken by the tank-guides. Would this entail any additional expense in the construction of the tank? Would any additional strain be thrown upon the guides in the tank; and if there was, would it be sufficient to cause any additional expense in the structure?

Mr. J. PARKINSON (Brighouse) assumed that the whole of the weight was taken by the tank-guides to the bottom lift; and when they came to erect a three-lift holder, these would have to be very strong, and bear a great weight. There was free space for the vertical sides of the second lift, and also for the bottom lift. For a single-lift holder, the arrangement might do where the spirals were held to the tank-wall; but when they came to the vertical sides of a second lift, there would, he thought, be a source of weakness there.

The PRESIDENT, referring to Mr. Veevers's remark on the æsthetic side of the question, said that economy with safety were the two main points they had to consider. He did not think there would be any difficulty in making arrangements to get to the top of the holder. The question of cost was, however, one that they ought to know something about; and if, as Mr. Gadd said, it would not be long before a holder on his plan was erected on a large scale, it would be interesting to see what it cost. He was sorry that some gentlemen like Mr. Newbigging, who usually took part in the discussion, were absent that day.

Mr. GADD said he felt as strongly as the President the absence of Mr. Newbigging, who would certainly have been of great assistance in the discussion. With reference to the objection of Mr. Meiklejohn, that there was no provision for climbing on the holder to clear the frozen lutes and so on, he had only to say that this was a matter of detail, which would have, of course, to be provided for. In the illustration which accompanied the paper, a hand-rail was figured round the top of the holder, such as was now common enough. A rail could also be put round each lift, and they would make a firm and safe road; and then a little straight iron ladder could be put up at some convenient point at the side of the holder. This was a little matter of engineering detail, which any engineer could design and carry out. As to the cost, if his plan were not cheaper, he did not know why anybody should be at the trouble to depart from the old lines; but Mr. Newbigging, in his estimate, put the cost of the guide-framing, roughly speaking, at 50 per cent. of the cost of the whole structure. He (Mr. Gadd) would not assert positively that this was a correct estimate. But if it were placed at 40 per cent., or any other figure, it was obvious that there must be an enormous saving by taking away the great weight of guide-framing; and it was on this that the commercial success of the invention must be shown. Whether Mr. Newbigging's estimate was under or over the mark, was a matter of considerable interest; but in itself it was quite immaterial. He thought a saving of 50 per cent. was not very far from the mark; for they not only saved in the framework itself, but they saved all the piers and foundation-stone preparation round the tank for building the guide-framing upon, which in cost of material and labour, must form a very important item. As to the tank-guides, which Mr. Ball referred to, there was no doubt that the strain would have to be taken up by the guides in the tank. It must be taken up somewhere; and the final resistance to the strain was in the spiral-guides round the tank. The strength lay in the fact that the spiral-guides were built into the tank, and could not give way, unless they were torn bodily away; and it would be very easy to design a method of fixing the guides into the tank, by long Lewis bolts, or something of that kind, so that no reasonable force could pull them out. This could be done without adding materially

to the expense, because the guides had to be fixed at present; and there need be no very great addition to the expense. As for the æsthetic question, this, of course, might be interesting; but at the same time it was perfectly true, as the President had said, that it could not be considered in the face of possible economy. But when all this was said, he confessed—though it might be prejudice in favour of his own child—that he saw a simplicity about the structure he had designed which commended itself to him. He compared it to the idea of the structure of the pyramids of Egypt, about which there was a grand simplicity greatly to be admired; and he was inclined to think that when they saw these holders on a large scale without guide-framing, they would admit they had a beauty which was absent from the ordinary structure of sticks and rods. However, this was quite a matter of taste; and for the present, they must adopt the dictum of the President that æsthetic considerations must give way to those of economy. Then he was asked as to the strains, and how the rollers were to grip the guide-rails and keep the holder firm. The explanation was this: In the present holders, if there was any wind pressure, the holder was driven horizontally to the framework on the opposite side to that from which the wind came. In his new holder the bottom curb was gripped and held; and the strain became one of the cantilever type. If they took an imaginary line from the top of the holder downward to the roller on the other side, they had the resistance, so to speak, of a direct strut through the centre. They had no strut, it was true; but they had a circular girder bond all round. The model stood an extraordinary strain; and he did not think the same model would have done this if with guide-framing.

The PRESIDENT remarked that, as in the case of Mr. Dalgliesh, they accorded to Mr. Newbigging a vote of thanks for his paper at the last meeting. They were, however, very much obliged to Mr. Gadd for being present that day.

THE IMPROVED STREET LIGHTING BY GAS IN THE CITY.—Alluding to the fitting within the last few weeks of some improved gas lanterns and burners to the lamp-posts in Cheapside, Queen Victoria Street, and some other City thoroughfares, our contemporary, *Money*, says: "The improvement in the light is very marked; although the new form of lamp-head is not perhaps the best suited to give gas fair play. Still we must be thankful for small mercies. It is a step in the right direction; and in time we may have a perfect form of gas-lamp in our streets. Anyway, it is better than being saddled with the expensive, delusive, will o' wisp electric phantom."

MR. ELLIS LEVER AND THE LEEDS GAS COAL CONTRACTS.—The Special Committee which was appointed to investigate the statements made some time since by Mr. Ellis Lever concerning the coal supplied to the Leeds Corporation Gas-Works (references to which have appeared in the JOURNAL from time to time) had their report—which is said to be a voluminous document—under consideration at a meeting last Thursday. A meeting of the Gas Committee was held later in the same day; and the report was laid before them and adopted. The report has since been published; and an abstract will be given in our next number.

THE "EVENING STAR" LODGE OF FREEMASONS.—It may be remembered that an absurd attempt (which signally failed, as it richly deserved to do) was a short time since made by one of the London daily financial papers, to bring discredit on the members of the "Evening Star" Lodge by commenting upon an anonymous letter published in its columns. We then alluded to the matter in an "editorial;" and no further mention would have been made of it but for a letter from "A Life Governor" of the Masonic Charities appearing in the last number of the *Freemasons' Chronicle*. We have pleasure in reproducing this letter, as it bears out most fully everything that was said about the question by those who had true masonry at heart. It is as follows:—"I had the pleasure of receiving an invitation to the recent installation meeting of the Evening Star Lodge; but, perhaps, at the time it reached me, I had misgivings as to the 'class' of men I was to meet there—I may tell you I had read in a public journal that this Lodge is a hot-bed of jobbery and corruption. Still, I decided to avail myself of the opportunity of personally judging, if possible, whether such a charge was justified. I need hardly tell you, Bro. Editor, that I found the members of the Evening Star Lodge as true gentlemen and as sincere masons as could be desired; and I think it a pity that the name of the Lodge, or any of its constituent members, should have been mixed up with a supposed scandal, or in any way associated with general misdoings in the gas world. Among the members of the Lodge, I found Bro. James Glaisher, an octogenarian, but as genial a craftsman as ever donned an apron. I felt that in such a frame it was impossible for 'treason to lurk.' I gathered that it was in the course of a trip to cloudland that Bro. Glaisher expressed the wish to become a Freemason; and he ultimately induced Bro. Magnus Ohren to propose him. This alone would, I think, entitle Bro. Magnus Ohren to the thanks of the members of the Evening Star Lodge; but he has other claims on their regard—not the least of which is his persistent desire to promote the welfare of the Masonic Charities. His efforts in this respect had a happy issue on the evening of my visit; inasmuch as the services of Stewards for each of the Masonic Institutions were secured at the meetings for the Festivals of 1889. I, for one, should like to see a few more Lodges following the example of the Evening Star; and if their only reward for so doing was to create envy in the outside world, they would at least have the gratification of knowing they had done something to attract attention."

STANDARDS OF LIGHT

At the Meeting of the Society of Arts on Wednesday last—Dr. J. Hopkinson presiding—Mr. W. J. DIBDIN, F.I.C., F.C.S., read a paper on "Standards of Light." The author had many of the standards mentioned in the course of the paper fitted up, and gave full explanations as to their operation.

The great importance attaching to the measurement of light in these days of severe competition between various luminous agents renders it, he said, imperative for the question to be kept well in view, to prevent its being lost in the whirlpool of political changes. To many of the public, the question doubtless appears to be one of those with which scientific men like to amuse themselves, but which can by no possibility have any effect on the practical details of our daily life. To show the immense commercial importance of the question in the City of London alone, it is only necessary to put forward the facts relating to the gas supplied by the three large Companies—viz., The Gaslight and Coke Company, the South Metropolitan Gas Company, and the Commercial Gas Company. In 1887, the amount paid by the public to these three Companies for gas was £3,354,794. Practically the whole of this amount was for 16-candle gas. Therefore £209,674 was paid by the public of London for one candle of light. When this item is added to the whole of the gas supply of the United Kingdom, it will be at once comprehended that in this seeming unimportant controversy, we have one of the most far-reaching questions of the day—one, in fact, which, as soon as it is fairly grasped by the public, will have to be speedily settled. Up to the present, it may be said that, in spite of the repeated inquiries, reports, papers before the various societies, and long correspondence in the newspapers, the question is looked upon as merely pertaining to the laboratory of the professional photometrist.

The keen competition between the gas companies and the electricians (which is but beginning to rear its head, and promises to soon become a serious matter) demands a settlement of the value of our English unit, the sperm candle, and the provision of a substitute for it which will at once be reliable in working, and capable of multiplication and repetition to an unlimited extent. Looking beyond our own nation, we see the question agitating the minds of conscientious workers in other countries. In France, the "Carcel" lamp has held its own since its introduction in 1800, much in the same way as our sperm candles still maintain their pre-eminence here. In Germany, the paraffin candle (used, however, in a far more scientific way than are our sperm candles) still holds the field. In America, in this matter, they try all things, and anxiously watch the older countries for guidance.

When gas was unknown, and oil-lamps and tallow candles ruled the roast, and the electric light was yet unborn, Bouguer, in 1760, proposed candles as the unit of comparison. In those days there were no official testing-stations, and no boards of directors to harass unhappy gas managers. Had Bouguer lived now, it is open to doubt whether he would have been bold enough to have made the same proposition. Sixty-four years later Ritchie proposed wax candles; but does not appear to have worried himself about the rate of consumption. Tallow, paraffin, stearine, and sperm have been all tried, and finally in this country sperm candles, weighing six to the pound, each candle burning 120 grains of sperm per hour, were adopted.

The contradictory results afforded by the various candles and the Carcel lamp gave rise to numerous proposals for substitutes. Amongst these are the four-wick lamp of Potter; Keates's sperm oil lamp; Bunsen and Roscoe's carbonic oxide flame; Crookes's alcohol and benzol flame; Von Wartha's ether flame; Vernon Harcourt's pentane air-gas flame and lamps, Fiddes's aperture; Wolf's screened moderator lamp; Hefner-Alteneck's amyl-acetate flame; Methven's screened Argand flame; Edgerton's screened petroleum reading-lamp; Rüdorff's screened Argand flame; Sugg's 10 and 16 candle tests (screened Argands); Dibdin's pentane Argand; Draper's, Zollner's, Schwendler's, and Violle's incandescent platinum and silver units; and various electric incandescent lamps. For the purpose of ascertaining the quality of ordinary coal gas, various devices have been employed, such as the length of a gas-flame at known pressures—i.e., "jet" photometers; but these cannot be classed under the head of "standards of light."

By a process of the survival of the fittest, only the pentane, the Methven screen, the pentane Argand, and the 10 and 16 candle tests, are now before the public as practical proposals for substitutes for the sperm candle in this country. In Germany, the amyl-acetate lamp of Herr von Hefner-Alteneck has met with great favour; and it would appear to have a good chance of being adopted as the legal standard. The objection of the English experts to the colour of the flame is so strong that there does not appear to be any probability of its being adopted here. In France, the melted platinum unit, in the form proposed by M. Violle, has met with some favour; but nothing practical has arisen from it up to the present. I tried a modification of this proposal in connection with my experiments conducted under the direction of the Metropolitan Board of Works, in which I melted platinum foil by the oxyhydrogen blowpipe flame, and took the light emitted at the moment of its melting as the indicator. This system was followed up by the Standard of Light Committee of the British Association, and elaborated by Mr. H. Trueman Wood, the Secretary of this Society, who arranged the foil so that it could be melted by an electric current. The British Association Committee also tried a suggestion of Professor Dewar, which provided for the end of a thick rod of platinum being kept in a molten condition by the

oxyhydrogen flame, and, while in that condition, being used as a standard after the manner of the Methven—a screen with a small circular aperture being placed immediately in front of the molten bead of platinum. None of these methods, however, gave reliable results; and there does not appear to be much hope of such a standard ever finding favour in this country. The Standards of Light Committee of the British Association for the Advancement of Science reported this year that, in their opinion, Professor Violle's molten platinum standard is not a practical standard of light, although they were quite prepared to agree to the adoption of the light emitted by a square centimetre of molten platinum as a unit, but not as a standard of light.

As it would be a work of supererogation to enumerate in detail all the work of the various official inquiries which have been made on the standards of light, I propose to discuss their results generally. The present official candles were described in the Metropolitan Gas Act of 1860 as "sperm candles of six to the pound, each burning 120 grains per hour." If, in fact, each candle would confine its rate of combustion to that quantity, doubtless a great part of our difficulties would never have arisen; but as it is a matter for remark when we do get a candle to burn this precise quantity, we have to fall back upon an experiment for correcting the variations due to variable rates of combustion—i.e., we weigh the candles before and after the experiment, and calculate the volume of light from the actual weight of sperm consumed in a given time. This method introduces the assumption that the luminous energy of a burning candle is always in proportion to the weight of sperm consumed in a given time. In order to avoid this assumption being too greatly strained, it is provided, however, that when the consumption falls below 114 grains per hour, or rises above 126 grains per hour, the test shall be rejected. The only other provision regarding the proper use of candles is that they shall attain "their normal rate of burning." The casual observer would probably assume that after all these precautions, surely the quantity of light emitted by a candle must be constant, within very minute limits. But by referring to the reports of various experts and committees, we shall see how far this is so. On the 25th of August, 1881, the Committee appointed by the Board of Trade reported "that candles are not of constant composition; that the melting point of the sperm varied; that the number and size of the threads in the wick, its treatment and closeness of plaiting of the strands, &c., affect the light of the candle, and that manufacturers differ in regard to them; that they found a difference of 15 per cent. in the average illuminating power of legal candles, and a maximum variation between two pairs of candles, of 22.7 per cent." In 1883, the Council of The Gas Institute appointed a Standards of Light Committee, and engaged the services of two of the most capable photometrists of the day—viz., Messrs. Heisch and Hartley. These gentlemen, after a most careful inquiry, in which they were assisted by the Committee, reported that—"In our experiments the differences in the indicated illuminating power by candles range from 1.3 per cent. to 16 per cent.; the average difference being 7.05 per cent. The maximum for 16-candle gas equals a difference of 2.56 candles; and the average, a difference of 1.128 candles. Such extremes as we realized are due to our resolve to study the behaviour of candles as sold for photometric purposes, which led us to use some, although they did not burn satisfactorily, specimens which in ordinary operations we should have rejected." The reporters then make a very important statement. They say: "We may here mention what we are convinced to be a fact—namely, that sperm candles generally now develop more light per grain of sperm burned than they did several years ago."

In July, 1884, the Special Purposes and Sanitary Committee of the Metropolitan Board of Works instructed me to report exhaustively upon the important subject of "Standards of Lights" and in the following February, I presented an interim report. [The author here read the section of the report relating to "Candles," which will be found on p. 577 of the JOURNAL for March 31, 1885, and which shows great divergencies in the results he obtained in his tests with candles.] Continuing, he said: In my second and final report, presented to the Committee on the 3rd of May, 1887, I stated that—"As will be seen from the tabulated results of the numerous experiments which have been made—viz., 2120, involving over 20,030 recorded observations—candles, as the only legal standard in this country, have been systematically used, with the result of still more than ever proving their unreliability."

While this repeated condemnation of the candles, when used in the legal manner, admits of no saving clause, it is only right to put again on record the fact that when the operator is allowed to choose his own candles, rejecting those which are obviously incorrect, although falling within the limits of the Act, and to burn them in the open, instead of shutting them up in a closed box with insufficient ventilation, very different results are obtainable. In fact, to such an extent has this been found, that it would probably not be difficult to formulate a manner of using them, and it might seem desirable to try the effect of such regulations. The difficulties that would, however, arise between conflicting interests in making such regulations, would probably be no greater than those in connection with the introduction of a new standard which should at once sweep away any uncertainty; and it is better, therefore, to work for a permanent change rather than for a temporary expedient, however desirable that may be.

Having arrived at the conclusion that the present legal standard is unreliable, it is necessary to inquire into the merits of the various proposed substitutes. Of these the pentane air-gas

standard of Mr. A. Vernon Harcourt undoubtedly holds the highest rank. This was first introduced in August, 1877, when Mr. Harcourt read a paper upon it before the Physical and Chemical Sections of the British Association, at their meeting at Plymouth. On the 8th of April, 1879, Mr. Harcourt forwarded to the Board of Trade a letter accompanied by a statement of a series of tests made with candles and with the new standard. In consequence of this communication, the Board of Trade appointed the Committee to which I have already referred, who, after very careful examination reported that—"Compared with the sperm candle, Mr. Harcourt's air-gas flame is exact and trustworthy as a standard of light." In 1883, the experts of the Committee of The Gas Institute, Messrs. Heisch and Hartley, reported of this standard as follows:—"We feel compelled also to say, although with reluctance, that we cannot regard Mr. Harcourt's standards as convenient, or at all suited for use in general photometry. They demand too much attention from the operator. With an ordinary photometer his attention is divided between the air-gas flame and observations of the disc. For it matters not how carefully either the prepared gas-flame or the lamp flame be adjusted (even when the former is controlled by a governor), the flame length will change, and a little change is sufficient to produce a serious error. Besides this the flames are very sluggish and unstable. The least current of air affects them, and causes them to swerve from the perpendicular; and where this takes place, observations at the photometer are useless. Further, they require a freedom from vibration of the room and of the apparatus which is rarely obtainable. . . . We certainly expected that the experiments would have been favourable to Mr. Harcourt's proposed standards, and regret that the contrary is the case."

In view of this strong condemnation, I was very careful in my experiments; and after most thoroughly trying both the original air-gas flame and the lamp, I was most convinced that the above remarks could not be accepted as applying to the former. In my first report, I stated that—"From the beginning to the end of my experiments, the whole of the tests were made with great facility; in fact, I was agreeably surprised at the simplicity and convenience experienced." And again: "The important statements made by Messrs. Heisch and Hartley as to the unsteadiness of the pentane flame have received great attention. I have tried all that is possible to vary the height of the flame by any means likely to accidentally affect it. I have let heavy weights fall on the floor of the testing-room; shut both inner and outer doors violently; the wall of the room has been struck—in fact, everything has been done, short of damaging the premises, to test the steady burning of the flame. Beyond a momentary leap at the instant of concussion, no effect whatever was produced; the flame burnt steadily; and the readings were the same after the experiment as they were before. I am not aware that my photometer-room is of peculiarly solid construction, or subject to less vibration than those at the testing-stations. The only conclusion I can therefore come to is that the results obtained by Messrs. Heisch and Hartley are not of the nature of those which might be looked for in practice." In my second report, after more extended trials, I stated that—"The pentane air-gas has completely borne out my former experience of it. . . . I have found the pentane air-gas to comply with every demand made upon it, and to answer to the full all the claims made for it by the inventor. The facts brought out by this inquiry have shown that the method of preparing the air-gas is at once easy and safe; that the measurement of the volume of gas used is simple and reliable; that the adjustment of the height of the flame is a matter of certainty; its steadiness all that can be desired, when due care is taken and proper apparatus employed; and that the colour of the light afforded is precisely the same as that of the standard comparison flame. . . . Should it be desired to use the flame in an unsuitable position as regards draught, the use of a chimney, as arranged by the inventor, entirely obviates all difficulty as regards steadiness, and renders the flame absolutely steady and free from the slightest sign of vibration and swaying."

This last point I consider of the greatest importance; and, where necessary, I should recommend the use of the chimney and cover in all practical work, as the use of an absolutely rigid flame, such as is thus obtained, renders the readings of the photometer infinitely more definite and sharp. In conclusion, I recommended the adoption of the pentane air-gas flame as a standard in the place of candles. As, however, many practical photometrists are of opinion that a standard of light of more than one candle is desirable for most purposes, and absolutely essential in some, I further recommended that, when the legal substitution of the pentane unit for the present candle be made, the Board of Trade should be empowered to sanction and authorize the use of such other standards and substitutes as that Board may deem fit and proper to be used in place of, and after comparison with, the pentane air-gas flame. The conclusions as to the fitness of the pentane air-gas as a desirable unit, arrived at by the Board of Trade Committee in 1887, and by myself in 1885 and 1887, have since been confirmed by the Standards of Light Committee of the British Association, who this year recommended its adoption.

In view of the possible adoption for practical work of a standard of higher value than the 1-candle pentane air-gas, it will be interesting to discuss the position of those proposals which seem to most nearly comply with the requirements of the photometrist. I have elsewhere stated that in my opinion it is most desirable that whatever standard may be used, it is advisable to avoid the use of common coal gas as a standard combustible; and therefore I have rejected the plain gas 2-candle unit of Mr. Methven and the coal

gas 10-candle test of Mr. Sugg. Fortunately, however, in so doing, it is not necessary to reject the principle of these convenient units, as the vapour of the pentane used by Mr. Harcourt supplies the means of providing a flame to each of these systems, independent of coal gas, or as an auxiliary to it. The now well-known "carburetted Methven" gives admirable results when the height of the flame is constant. Unfortunately, however, my experience of this standard is that various operators may disagree as to the height of the flame; and a little over-discretion or carelessness, as the case may be, will cause very different results. At the time of the Board of Trade Committee, in 1881, Mr. Methven used the original pattern, in which simple coal gas was burnt; and that Committee condemned the system in consequence of the variability due to differences in the quality of the gas used. To obviate this objection, the inventor enriched the ordinary gas by causing it to take up the vapour of pentane on its way to the burner, and altered the form of the slot to suit the enriched gas.

In speaking of these two forms of Mr. Methven's proposal, Messrs. Heisch and Hartley, in their report already referred to, said: "It will thus be realized that the range in the qualities of gases with which the Methven plain gas standard can be safely used, is much wider than is generally supposed; as in our experiments the extremes are 13.65 and 22.4—a range of 8.75—candles. . . . The Methven standards are simple in construction, not liable to get out of order, and extremely easy to use. They do best (like candles) in an open photometer; but can be readily used in a closed one, if due care is taken to freely ventilate the photometer, and avoid violent air-currents—conditions which are extremely difficult to fulfil with closed photometers. . . . The only conclusion which can be drawn from such a mass of evidence is that the Methven units are not only perfectly reliable instruments in ordinary gas testings, but are suitable for use in photometric investigations of a much more refined character." This is strong evidence, and leads to the conclusion that at all events we have here a valuable substitute for candles; the main objection to the method being the uncertainty as to the height of the flame. Were there no other proposal equally simple in character, and free from the same objection, it would be conclusive. But in view of the fact that in the modified form of the 10-candle test, which I have called the "Pentane Argand," we have a most reliable standard, free from all objection from the height-of-the-flame point of view, as I shall be able presently to show; independent of coal-gas, and atmospheric influences, such as temperature or pressure; possessed of the advantage of being a decimal factor (viz., ten candles); and furthermore being a desirable unit to use in coal gas testing during foggy weather, as the distance of the opposing lights from the photometer disc is for that purpose practically equal—the Methven would seem to have been distanced in the race by so formidable a competitor.

The arrangement possessed of these advantages is very simple; no meter, governor, or other measuring or controlling adjunct, beyond a simple tap, being necessary. It is merely a small Argand burner suited for burning air-gas. Supported 2.3 inches above the steatite burner, is a screen to cut off the light emitted from the top of the flame, and indicating rods to assist in regulating the flame to a height of 3 inches. The standard combustible is the vapour of pentane. This is driven forward to the burner by a current of air from a holder or pressure-bag, as may be convenient—about $\frac{1}{2}$ cubic foot of air per hour being required. The pentane is contained in a carburetter precisely similar to that of Mr. Methven—in fact, I used one of his pattern; and the air is carburetted with the pentane in the same way that he carburettes the coal gas for his later form of standard. A variation in the temperature of the carburetter makes no difference, as I obtained the same result when I filled the trough of the carburetter with water at 90° Fahr., and then with ice and water. The flame should be adjusted to a height of 3 inches, for uniformity; but if from accident the flame falls to 2½ inches or rises to over 4 inches, no difference is observable in the volume of light emitted under the screen. I have ascribed this remarkable result to a compensating action in the blue portion of the flame, which is reduced in size when the luminous portion is lowered and contracted in bulk, and thus causes a greater length of the white flame to be seen under the screen; and inversely, when the flame is raised and expanded in width, the blue portion is also increased, and thus compensates for the otherwise greater intensity of the white portion. From the manner in which this proposal has been received, I am in hopes it may form a neutral ground on which, for a time at least, conflicting interests may meet to their mutual advantage.

The statement of Messrs. Heisch and Hartley already quoted, to the effect that candles develop more light per grain of sperm now than formerly, is a most important one, and cannot be passed over in silence, as such a proposition will doubtless afford scope for serious contention. [Mr. Dibdin here quoted at length from his first and second reports on this point. See p. 578 of the JOURNAL for March 31, 1885; and p. 291 of the JOURNAL for Aug. 9, 1887.] Proceeding he said: That the average results by candles were too high is shown by the fact that, out of 81 averages, no less than 14 were above 17.5 candles, and 37 above 17 candles—results admittedly too high for an Argand flame only 3 inches in height—while, on the other hand, the average results by candles were under 16 candles only on six occasions, and on three of these the low result was confirmed by the other standards; so that on only three days did the candles indicate results lower than would appear to have been the true value of the comparison flame.

The report of the Standards of Light Committee of the British Association fully confirmed these results, and explained them upon the following grounds. Manufacturers endeavour to remove the liquid portions of the spermaceti (sperm oil); and thus obtain the "dry" spermaceti as free from it as possible. The resulting product has a higher melting point; and therefore burns with less facility. The manufacturers have now so far succeeded in this direction, that candles have to be made with larger wicks; the result being that they give less light for a given consumption than candles with smaller wicks. Thus the effect in the improvement in spermaceti candles has been that standard candles give less light than they gave ten years ago, and probably still less than they gave at earlier periods, when the average consumption of candles of six to the pound was 140 grains per hour.

Having now arrived at the point at which candles are shown to be untrustworthy, and a suitable substitute found in the pentane air-gas flame, aided, for practical purposes, by the pentane Argand, it may be of interest to glance at the position of the question on the Continent. In presenting a report of the Committee on Candles to the twenty-eighth annual meeting of the German Gas and Water Society, in September last, Dr. Krüss stated that the Committee thought to have fulfilled their instructions by establishing the German Society's paraffin candle, which had for the last year been manufactured under the Society's direction at the works in Waldau; and that the Society had determined no longer to issue six to the pound but ten, in order to obtain a length of candle more suitable for practical use. Each single candle was provided with a wick in a perfectly central position, which is more easily accomplished in the shorter candle than in the long one. Care had been taken that the new candles have exactly the same photometrical value as the former ones. While the work of the Committee had been devoted to the control of the production of the standard candles, and to supplying these to the consumer, they had occupied themselves with the amyl-acetate lamp, and had already come to the conclusion that it was an extremely comfortable standard for every-day use. This decision has been subsequently confirmed. From the results of a number of tests made by members of the Society generally, it was agreed that for daily use for the present there was no better, more practical, and comfortable, and less time-consuming means for light measuring. It appeared, however, that the proportion of the intensity of the lamp to the different candles had not been accurately determined. The intensity of the German Society's candle was variously stated to be 1·2, 1·234, 1·21, 1·26, 1·12, and 1·20 amyl-acetate lamps with 40 mm. height of the flame. Still greater differences had been found when comparing the English candle with the lamp. It was evident that further close and continuously systematic trials were necessary to determine its exact value. From a series of experiments conducted by Dr. Liebethal, of Hamburg, it appeared that the measurements of the wick tube, and consequently the diameter and length of the wick, need not be adjusted with extreme accuracy, but that the height of the flame was very important, and that the mean variations between two amyl-acetate lamps come within 1 per cent. The Committee had, therefore, resolved in conformity with the experience up to the present, that the steadiness and easy application of the amyl-acetate lamp, even in its present form, recommends it as a suitable means of comparison for light measurements, and that further trials are necessary to determine the proportion between the intensity of the amyl-acetate lamp and that of the candle. It was therefore proposed to constitute the Committee on Candles a Committee on Light Measurements, to make these trials together with suitable experts, and that the Physical and Imperial Technical Institute of Charlottenburg be requested, through the Imperial Board of Home Affairs, to lend their co-operation in the investigation.

This decision is of great importance. From the results of the very numerous tests made by myself and others with the amyl-acetate lamp, it is evident that its convenience and steadiness are all that can be desired; but, as I have stated, its colour is against it in the opinion of the English experts. Could this be overcome, it would be a very convenient standard; but all efforts up to the present have failed to produce a light of the character of that given by the pentano and candles at their best. From my experiments, I found that the 40 mm. height of flame was too low; but on raising it to 51 mm., or 2 inches, it gave results identical with the average English candle as determined by both the pentane and Methven screen. I am informed by Dr. Krüss, of Hamburg, that while they agree that the colour of the amyl-acetate lamp is very unfavourable, they did not know of anything better; and therefore had to put up with it. They are now trying the improved pentano lamp of Mr. Harcourt; but the experiments are not yet concluded.

One of the objections put forward to a change of standard in England is that no general desire has been expressed to that effect. It has already been shown that the authorities of the Board of Trade—the controlling authorities for gas-testing purposes in London—the gas interest generally, as represented by The Gas Institute, and the British Association, have all joined in one condemnation of the existing candle, and in demanding an alteration; and, with one exception, that such alteration should consist in the adoption of Mr. Harcourt's pentano air-gas flame. It has also been said that no alteration can be made in London without affecting the country generally. If the regulations applying to the candles were general, that would be a strong argument; but at the present moment there are virtually two different standards

in use. In the Metropolis Gas Act, the standard candle is defined as "sperm candles of six to the pound, and burning at the rate of 120 grains per hour." In the instructions of the Gas Referees, it is prescribed that the candles shall attain their "normal rate of burning," and no mention whatever is made of their *manner* of burning. In the Gas-Works' Clauses Act, 1871, however, which applies to the country outside the Metropolis, it is specifically laid down that the tip of the wicks shall be glowing and slightly bent; and thus a distinct condition is indicated. True, most photometrists decline to use the candles in any other manner. But it has been repeatedly argued, on behalf of the gas authorities, that an examiner has no discretion, provided the consumption of the sperm is within the prescribed limits; so that a test is a perfectly legal one when the wick is upright, and the candle consequently giving less light, with the result of indicating a higher value to the gas than it otherwise would have. Such a condition of things does not argue well for the maintenance of uniformity in the manner of testing the value of the gas supplied in such enormous volumes to the public. If those outside the Metropolis are satisfied with the better protection they now have, it is no reason why a less sufficient protection should satisfy the inhabitants of London. It cannot be imagined, however, that the general public of the country are aware of the present defective condition of the question. In all other matters affecting the commercial transactions of daily life, the most stringent regulations are in force to maintain almost mathematical accuracy in the various weights and measures used. In the matter of light alone the utmost laxity prevails, and when it is considered that such vast interests are at stake, it seems almost inconceivable that the legalization of an accurate standard of light, such as can now be obtained, should be delayed for a moment longer than that required to take the necessary steps.

At the close of the paper, Mr. Dibdin showed on a screen a number of candles, the wicks of which had assumed a variety of forms in burning, which affected more or less the light afforded.

In the course of the subsequent discussion,

Mr. A. G. VERNON HARCOURT, F.R.S., said that Mr. Dibdin was entitled to the best thanks of those present for the pains he had taken to illustrate the subject which he had brought before them. He had never attended a lecture of this character which had been so well illustrated as this one. The concluding illustration, in which the wicks of different candles were shown to have assumed various forms in use, was particularly interesting. The difficulty of the question which they had before them was that it was not a purely scientific matter; if it were only scientific, it could be very well worked out. For the business of gas testing, the standard that had to be used was unfortunately a variable one; and this was likely to be the case for a considerable time to come, until a larger interest was taken in the matter. It was 8 or 9 years since the Board of Trade appointed a Committee to consider this subject of the standard of light; and the Board went to the trouble of sending round the report of the Committee to those who, they thought, would be interested in the question. The result was very disappointing to them; for hardly anyone took interest in it. In consequence of this, the Board had so far held their hand; and nothing had been done. The matter was really of considerable practical interest; and perhaps the best contribution he could make to the discussion was to relate an example of the unreliable character of candles which had come under his immediate observation. He received a letter from the Town Clerk of Gloucester some time since, requesting him to visit the city in order to find out what was the cause of the difference of opinion which existed in regard to the testing of the gas, and which had created a good deal of unpleasant feeling in the place. The Local Authority had a Gas Examiner, who, in testing the gas, sometimes made out its value to be very near, and at other times greatly below the standard quality. The Company tested the gas at their works; and they were convinced that it was considerably above the standard. They had confidence in their own testing; and considered they were being very hardly used. He (Mr. Harcourt) went down to Gloucester, and tested the gas both at the works and at the testing-station in the town. He satisfied himself that the testing had been made in the most conscientious manner at both places; and that the whole of the dispute which had arisen had been brought about by the difference in the candles. He took candles from one testing-place to the other; and to some extent the difference was the variation, which Mr. Dibdin had alluded to, in the latitude which one gas examiner would allow himself in dealing with the candles as compared with another. The Local Authority Examiner, if he found the candles burning with such wicks as had been shown on the screen by Mr. Dibdin, rejected them until he found one that did burn properly. Of course, the result of the testing was largely dependent upon whether a selection was made of the candles, or whether they were used as they came. He took samples of the candles home from Gloucester, and found that the candles used at one of the testing-places contained more threads in each strand of the wick than in those used at the other. The more threads there were in each strand, the less light would there be given; and in these candles there was a considerable difference in the amount of light obtained. Here a great deal of unpleasantness had arisen, without any blame to either of the gas testers (who had both carefully and conscientiously done their work), but which had been produced by the discrepancies which the candles brought about.

Mr. ALEX. SIEMENS wished to say a few words in favour of the amyl-acetate lamp in spite of Mr. Dibdin's condemnation, because

for practical use—of course, he spoke as an electrician, who had often to make comparisons—the lamp was simplicity itself, and had a very great advantage, which was not wholly done away with by the colour. Mr. Dibdin, in his experiments, had unfortunately increased the height of the flame from 40 mm. to 51 mm., which made the colour of the light all the worse. The amyl-acetate lamp was not, of course, intended to be an English standard equal to the standard candle; but they (Messrs. Siemens) could easily have supplied Mr. Dibdin with a lamp which would have given an exact English candle. Since they had supplied the lamp to Mr. Dibdin with which he had experimented, they had found out that the amyl-acetate should be perfectly pure to give good results. To be quite safe, Mr. Dibdin obtained the oil from his firm; but they found out afterwards that it was a bad consignment. (Laughter.) The conclusion at which the German gas engineers had arrived was that, for a practical standard, the amyl-acetate was the best for measuring gas-light, because the colour of the light was very much like that of gas; and therefore it was all the easier to compare. In this connection he would mention that a great difficulty was also found, when comparing lights, in this—that the eyes of the various observers were affected differently; and therefore it was very difficult to compare two flames that were not exactly alike. To overcome this, Mr. Werner Siemens had designed the platinum lamp which Mr. Dibdin had alluded to. (The speaker briefly described the lamp by the aid of a specimen which Mr. Dibdin had present.)

Dr. DUPRE said he was present that evening to learn rather than to give any information. Of course, the great thing in a standard must be that it could be multiplied—in other words, that the operator could get a test as often as he pleased. He should like to know whether Mr. Dibdin obtained the same results with different pentane flames.

Mr. WILLIAMS remarked that it was some four years ago since Mr. Siemens was good enough to send him an amyl-acetate lamp. He made a considerable number of experiments, which convinced him that the lamp was even superior to any other standard devised up to that time—not even excepting Mr. Vernon Harcourt's pentane standard, although it was right for him to say that up to that period, he had had no particular experience of Mr. Harcourt's pentane lamp. He was quite aware of the fact that this amyl-acetate lamp was not equal to the English standard candle; and he was surprised that Mr. Dibdin should have turned the flame up, so as to make a kind of fog. Messrs. Siemens, he understood, were making this amyl-acetate lamp to equal the English standard candle. The lamp, in his opinion, could be much improved; and he should suggest that it should be made with a double wick, so that two flames could work at one time. He believed that the tube containing the wick in the lamp was made of German silver; and it should, he thought, be of thin platinum foil, as, if the amyl-acetate contained the least trace of acid, the German silver tube became corroded in a very objectionable manner. He also considered the flame should start from a wider base. With regard to the point incidentally mentioned by Mr. Dibdin, about the glass chimneys used in these various standards, he must say they were very objectionable indeed; for notwithstanding however carefully they might be selected, they often contained many faults which affected the testing. He should recommend the use of a chimney which he had employed for a long time, and which was made of an extremely thin strip of mica. With respect to the platinum standard, he had had but little to do in experimenting with it; but he did not think it was one which was very promising. Very little was known of commercial platinum; but a great deal was known as to the differences in the fusing points of this material. If platinaums of various fusion points were used, the light emitted per unit of surface would be different. He considered that solidified platinum was the best for the purpose. In his opinion, before the public would consent to have the present candles condemned, they would demand that some more rigorous attempt should be made to perfect the standard candle than had yet been made. Since the time when candles were recommended for use, they had been improved in many respects; and he felt perfectly certain, if Mr. Dibdin were to invite one or two of the most distinguished candle-makers of London to meet him, that a great deal of advantage could be gained—even in the interim between this and the time when new standards might be adopted. He thought it would be an advantage if, for the time being, they could secure better candles in two respects. In the first place, the wax was now of varying composition; and he believed no particular pains were taken to see that the mixture was constant. Secondly, there was no definition given as to the number of the threads of the wick, the tightness of the plating, or the special tension of that particular thread which caused the twist or curve. The last was the most difficult point to attain, and was the one that gave rise to most trouble in photometry. With regard to the various illustrations of wicks which Mr. Dibdin had shown, skilled photometrists could always tell the proper form the wick should take; it should approximate to a parabolic curve. As to the latitude a gas examiner should allow himself in testing, he thought those who permitted themselves least latitude, were probably the best examiners.

Mr. DIBDIN, in reply, observed that Mr. Harcourt had well illustrated one of the difficulties that were constantly met with in testing with candles; but he did not think it necessary to make any comment upon that, as it was the experience of all gas testers. Mr. Siemens had spoken of the colour of the amyl-acetate lamp being affected as he (Mr. Dibdin) increased the height of the flame.

Now this was not so, though probably he might slightly have increased the colour. They found, however, that the colour of the flame was against it even when turned to the same height as that prescribed by the inventor (Herr von Hefner-Alteneck). But his experience was not singular in this respect, as was evident by the statement of Dr. Krüss, which was mentioned in the course of his (Mr. Dibdin's) paper. In regard to the oil which Mr. Siemens sent him for use in the lamp, he did not confine himself to that, but obtained some from elsewhere, which was sent to him as pure amyl-acetate; and with this they found the colour of the flame still maintained. Dr. Dupré spoke of the multiplication of the standards, and whether he (Mr. Dibdin) could get the same results with different burners. He had used several forms of the pentane burner, and had obtained precisely the same results from them; but he did not see how very slight variations could make much difference. Mr. Williams had touched upon the question of candles, and thought that if they were to invite the candle makers to institute a set of regulations, they would probably get better results. He (Mr. Dibdin) could not agree with him, as, in his opinion, this question had been well thrashed out. He had asked the manufacturers to make him candles in various ways; and yet he always experienced the same difficulties. He did not think many people had taken more trouble than Mr. Harcourt to improve candles; and he had shown that it was impossible to improve them under the legal definitions existing at present. The German Gas and Water Society had issued elaborate instructions for the making of candles; and they also superintended their manufacture, and sent them out. The Society's candles were distinguished by a red thread; and they not only used these particular candles for testing, but they went so far as to say that the height of the flame should be checked as well. This was one of the greatest safeguards that the candles could be surrounded with. But still it was found that they were in the same position as English gas testers in regard to candles; and their Committee on candles had been constituted a Committee to investigate the various standards of light. The Germans were not behind other people in experimental investigations; and they had come to the conclusion that they must have a fresh investigation into this subject, and invite the co-operation of the Imperial Technical Institute.

A hearty vote of thanks was then accorded to Mr. Dibdin for his paper.

THE USE OF WATER GAS AT THE LEEDS FORGE.—An account has recently been published by *Le Martin* of a visit of one of its correspondents to the establishment of Mr. Samson Fox in Leeds, in order to ascertain some particulars as to the adaptation of water gas to metallurgy. In the course of his communication, the writer remarks: "For the welding of tubes of great thickness—30 mm. and upwards—a combustible of a more powerful heating intensity than that of coal or Siemens gas was needed. For tubes of 15 mm., four workmen can only weld 2 metres a day, which brings the price per metre to 22 frs. By the use of gas from water, three men weld 2½ metres in an hour; thus reducing the cost price from 22 to 4 frs. per metre. In Messrs. Fox's works 1000 cubic metres of gas are produced in an hour." It has been said that America is the country of natural gas; but the writer claims priority of discovery for his compatriot Dr. Laffont.

THE MISERY OF OIL LIGHTING AT ERITH.—A local correspondent writes: However much "patting on the back" is indulged in by a few members of the Erith Local Board because they are able to show a "paper economy," so far as the experiment here with oil-lighting has proceeded, as compared with the cost of gas, there can be no possible doubt of the fact that the majority of the residents of this riverside town are anything but pleased with the change. It is, of course, most easy to show a saving on paper; but when one takes into consideration the incidentals (not to say the discomforts), this economy dissolves into the air. For instance, at Erith, the nearness of the town to the River Thames, and its situation in the valley, expose it to the rudest blasts of "Boreas;" and whenever there is a storm off the Kentish Coast, the Erithians do not escape its violence. The sequence to this is that the oil-lights, not possessing such stout and resisting qualities as gas, become extinguished as soon as the wind gets a little high; and men have to be employed to go from lamp to lamp with rekindling torches. It is all very well for the self-satisfied members of the Local Board to make allowances for these vagaries of the oil-lamps, by referring to the force of the tempest; but the singular thing is the absence of all cause for such palliations when the town was illuminated with gas. This, however, appears to be but one of the minor discomforts which are being put upon the people of Erith. A street or road in pitch darkness is decidedly unpleasant when the ratepayer pays for light; but this pales into insignificance when placed alongside the complaint which is now being made to the effect that during the recent boisterous weather the oil itself has been blown out of the reservoirs of the lamps, not only bespattering the foot-paths, but rendering it a difficult matter for passing pedestrians to avoid the splashes of oil thus blown about. Of course, this is due to leaky lamps; and when complaints are made, orders are forthwith given for the defects to be remedied. But those people who are splashed by the oily drippings, and whose clothes become spotted and spoiled, must be forgiven by the Local Board if they cannot recognize the wisdom of the new departure. Neither must members of the Board begin to get angry when pointed to their self-sacrificing characteristics, if in the near future they receive numerous intimations to the effect that gas-lamps do not leak and bespatter pedestrians with foul and noisome messes.

NEW APPLICATION OF GAS.

A patent has lately been taken out by Mr. Bryan Donkin, jun., for a rather novel application of gas for heating the cylinders of steam-engines; and a short notice of the proposal will be of interest to our readers.

Around the cylinder are placed a series of Bunsen burners; so arranged that the flames are in actual contact with the metal of the cylinder. The temperature is thus raised considerably; and the hotter metallic surfaces diminish the initial condensation of the steam, and increase the re-evaporation of steam and water towards the end of the stroke. Instead of hot steam having to come into contact with relatively cold surfaces, they are made much hotter than is usual, and hotter than the temperature of steam. It is, of course, well known to engineers who have actually experimented in this direction, that steam jackets, or engines jacketed with boiler steam, give a considerable economy, varying from 10 to 25 per cent., depending partly upon whether the jackets are efficiently applied, and partly upon size of the cylinder or cylinders. But with such steam jackets the temperature is limited to the pressure of steam in use. With the Bunsen flame, however, there is not the same limit; and a much higher temperature can be generally obtained. Some preliminary experiments have been made by Messrs. Donkin and Co.; and diagrams were taken with and without such hot-cylinder jackets. The economy in weight of feed water or steam per indicated horse power was shown to be at least 25 per cent. Against this, there is to be put the cost of the gas; and the net saving will depend upon the cost of fuel, less the cost of gas, at any place. Of course, more power can be got out of the same sized cylinder with the hot surfaces, as less steam is used for the same power, and the work or evaporation from the boiler diminished. No attempt is made to superheat the steam before its arrival at the cylinder, which has often been done with known results. All that is done is to superheat the metallic surfaces brought in contact with the hot steam, where work and expansion takes place. Work, of course, means that some water is produced; and this probably is partly re-evaporated.

In regard to this matter, we might ask our readers if they know of any exact experiments on the comparative calorimetric value of Bunsen gas-burners against ordinary gas-burners, showing: (1) With Bunsen burners, the number of degrees that 1 lb. of water can be heated in a certain time with a consumption of so much gas and so much air. (2) With ordinary burners of a certain type, the number of degrees 1 lb. of water can be heated without air, for the same consumption of gas in the same time. (In the latter case there would no doubt be some little accumulation of soot.) In other words, the number of thermal units given out per minute per cubic foot of gas burnt in the two cases.

PRIVATE BILL LEGISLATION.—Questioned by Mr. Craig Sellar, in the House of Commons last Thursday, as to whether it was the intention of the Government to introduce a measure next session dealing with the subject of Private Bill Legislation, the Chancellor of the Exchequer said it was impossible for the Government to determine at present the exact course of their legislative proposals next session. It must be remembered that there were several important measures of the present session which would have to be reintroduced, and to which must be assigned a prominent place. He, however, assured Mr. Sellar that the subject of Private Bill Legislation would receive the most earnest attention of the Government when they come to make up their legislative programme, and that they would be very glad if a measure dealing with the matter could be introduced next session.

ELECTRICITY AND ARTESIAN WELLS.—The discharge of water from artesian wells has for many years been employed as a motive power in France. In the city of Tours there is an artesian well which drives a hydraulic wheel 7 metres in diameter, and works the machinery of a silk factory. At Grenelle the heat of the water issuing from a deep well is utilized in warming buildings. A project is now before a Commission of the Municipal Council of Paris, having for its aim the utilization of the power obtainable from the new artesian well in the Place Hébert, at La Chapelle. There are now three important artesian wells in the Paris basin; that of Grenelle being the oldest, and that of Passy the most productive. The new La Chapelle well is, however, situated in an industrial quarter of the Eighteenth Arrondissement; and is thus well adapted for the experiment of producing motive power. Besides these, there are a number of private artesian wells in Paris belonging to manufacturers. The La Chapelle well was finished in March last; having been begun 24 years ago. It reaches a depth of 720 metres, and the water, left to itself, rises to a height of 35 metres above the mouth. It furnishes 6000 cubic metres of water every 24 hours. The proposal is to utilize the power furnished by the well in generating and distributing electricity for lighting and motive purposes. One object mentioned is the lighting of the park of the Buttes Chaumont, which is situated near the well. Before now electricity has been generated in this manner. At Ponce de Leon, in Florida, there is a hotel having a powerful artesian well, which drives a turbine-wheel and dynamo; thus generating the current necessary to light the building and its grounds. At Yankton, in Dakota, there is a flowing well which drives the dynamos of an electric light company. The well is 600 feet deep; and the water on issuing from it is conducted to a reservoir 30 feet above the turbine which is employed to actuate the dynamos.

Correspondence.

[We are not responsible for the opinions expressed by Correspondents.]

THE REMOVAL OF HINDRANCES TO THE CONSUMPTION OF GAS.

SIR,—Some of the papers which are read at Gas Association and other meetings, and afterwards printed in your columns, with reports of the discussions which arise thereon, must be most perplexing to many of your readers, owing to the different and various methods in force under respective Gas Authorities. I refer particularly at present to the payment of deposits, the rent charged for meters and gas-stoves, and the cost of laying service-pipes. There is evidently no uniformity whatever in dealing with any of these matters either in Corporations or Companies; and it is probable that the practice of no two Authorities is alike.

As to the question of deposits. In some towns the rule seems to be to require deposits from all consumers, with exceptions under special circumstances. In other places this rule is exactly reversed; no deposits being required, except in certain well-defined and special cases. It will be manifest, therefore, that any discussion of the subject without this previous explanation as to custom must be pointless and unsatisfactory. I submit that the payment of deposits under the latter rule is perfectly justifiable. The profit arising from the consumption of gas in these special cases, without a deposit, would be more than swallowed up by bad debts. Increase of business may be had at too great a price; and on these terms it is certainly not desirable.

As to the question of charging rent for gas meters and stoves, we are again met with differences in practices and circumstances. In some large towns, many persons prefer to hire their meters or stoves; while a large number prefer to purchase one or both. How are the owners of meters and stoves to be dealt with equitably, if and in case the Corporation or Company decide not to charge meter or stove rents in future? It is contended by some persons that the initial price of gas ought to cover *all cost*, including meter and stove rents, service-pipes, and some internal fittings; but I fear that the proper re-adjustment of the present state of things to the new conditions which would arise when these charges cease to be made would be very difficult, if not altogether insurmountable.

In some towns I understand, it is not the custom for builders or owners of houses or other premises to lay any piping or to supply or fix any internal gas-fittings whatever; whereas, in other places—especially in large towns—the reverse is again the custom. Piping is almost invariably laid to the principal living and bed rooms, and most of the common brackets are also fixed, and in some cases chandeliers and brackets complete. The cost of doing all this is included in the rent of the house; and this to me seems a fair and reasonable arrangement. As well might the price of candlesticks be charged in the price of candles, as the cost of gas-fittings be charged in the price of gas. Such fittings, however, when provided by the owner of a house, become fixtures; and their cost may legitimately be provided for and included in the rent, as in the case of other fixtures.

I do not know what the custom is as to the charge made for service-pipes. In the large town from which I write, the custom is to make no charge at all, except for so much of the pipe as is required to be laid through private property—such as the small gardens or courts in front of houses or other premises through which the pipe has to be taken.

I apprehend that much of the difference in procedure to which I have referred, arises from the different circumstances in which towns are placed as compared with one another; and especially to the fact that, in small towns, the whole of the consumers (and much in relation to their circumstances) are personally known to the gas officials, which is utterly impossible in large towns. Further, that the working-class inhabitants of the smaller towns are much less migratory than those of the larger towns; hence the necessity for more stringent rules in the one case than in the other.

My object in writing is to urge that gentlemen who read and discuss papers on these subjects, and such as these, should let it be clearly known what they really mean and what they condemn or approve.

Dec. 20, 1888.

SELRAHC.

THE POSITION OF GAS ENGINEERS.

SIR,—As Manchester has figured rather prominently in this discussion, I should be glad if any of your readers could inform me whether the rumour be true that the Bradford Road works—which were erected from designs selected and approved by Messrs. Hawksley, Livesey, and King—have already cost the Corporation of that city a sum of between £400,000 and £500,000, upon a large portion of which commission was paid, in addition to the £1500 mentioned by Mr. Livesey as the cost of the preliminary advice. Also whether the manufacturing and storage capacity represented by that outlay is regarded as so insignificant as to be sufficiently looked after by a Foreman acting under the supervision of the Resident Engineer of another works at a distance.

Dec. 21, 1888.

ENQUIRER.

SERIOUS COMPLAINTS AGAINST THE QUALITY OF YEADON WATER.—At the last meeting of the Yeadon Local Board, Dr. Usher attended, and said that as a medical man he had felt it his duty to come before the Board to lodge a complaint against the Yeadon Water-Works Company. It was purely out of regard for the health of the people of the township that he attended. He had discovered that the Company were allowing a very large portion of their gathering-ground to be manured. The night-soil was of the very worst character; and a portion of it was spread, while the other portion was in lumps. Some of the manure was even spread over the pipes which, without any filtration whatever, conveyed the water to the consumers. This was a very demoralizing, filthy, and disgraceful piece of business; and he could not speak too strongly about it—more especially as he had previously had to complain about the very same thing. As there were infectious diseases in the immediate district, it was important that the Board should take the matter in hand immediately. The speaker produced a sample of water (taken from a tap at the top part of the town), which was of a very black and sludgy character. Mr. Smith, one of the members of the Board, said he had himself seen the manure being put on. On the suggestion of Mr. Lees, a Committee of the Board were appointed to view the alleged nuisance.

NEW APPLICATION OF GAS.

A patent has lately been taken out by Mr. Bryan Donkin, jun., for a rather novel application of gas for heating the cylinders of steam-engines; and a short notice of the proposal will be of interest to our readers.

Around the cylinder are placed a series of Bunsen burners; so arranged that the flames are in actual contact with the metal of the cylinder. The temperature is thus raised considerably; and the hotter metallic surfaces diminish the initial condensation of the steam, and increase the re-evaporation of steam and water towards the end of the stroke. Instead of hot steam having to come into contact with relatively cold surfaces, they are made much hotter than is usual, and hotter than the temperature of steam. It is, of course, well known to engineers who have actually experimented in this direction, that steam jackets, or engines jacketted with boiler steam, give a considerable economy, varying from 10 to 25 per cent., depending partly upon whether the jackets are efficiently applied, and partly upon size of the cylinder or cylinders. But with such steam jackets the temperature is limited to the pressure of steam in use. With the Bunsen flame, however, there is not the same limit; and a much higher temperature can be generally obtained. Some preliminary experiments have been made by Messrs. Donkin and Co.; and diagrams were taken with and without such hot-cylinder jackets. The economy in weight of feed water or steam per indicated horse power was shown to be at least 25 per cent. Against this, there is to be put the cost of the gas; and the net saving will depend upon the cost of fuel, less the cost of gas, at any place. Of course, more power can be got out of the same sized cylinder with the hot surfaces, as less steam is used for the same power, and the work or evaporation from the boiler diminished. No attempt is made to superheat the steam before its arrival at the cylinder, which has often been done with known results. All that is done is to superheat the metallic surfaces brought in contact with the hot steam, where work and expansion takes place. Work, of course, means that some water is produced; and this probably is partly re-evaporated.

In regard to this matter, we might ask our readers if they know of any exact experiments on the comparative calorimetric value of Bunsen gas-burners against ordinary gas-burners, showing: (1) With Bunsen burners, the number of degrees that 1 lb. of water can be heated in a certain time with a consumption of so much gas and so much air. (2) With ordinary burners of a certain type, the number of degrees 1 lb. of water can be heated without air, for the same consumption of gas in the same time. (In the latter case there would no doubt be some little accumulation of soot.) In other words, the number of thermal units given out per minute per cubic foot of gas burnt in the two cases.

PRIVATE BILL LEGISLATION.—Questioned by Mr. Craig Sellar, in the House of Commons last Thursday, as to whether it was the intention of the Government to introduce a measure next session dealing with the subject of Private Bill Legislation, the Chancellor of the Exchequer said it was impossible for the Government to determine at present the exact course of their legislative proposals next session. It must be remembered that there were several important measures of the present session which would have to be reintroduced, and to which must be assigned a prominent place. He, however, assured Mr. Sellar that the subject of Private Bill Legislation would receive the most earnest attention of the Government when they come to make up their legislative programme, and that they would be very glad if a measure dealing with the matter could be introduced next session.

ELECTRICITY AND ARTESIAN WELLS.—The discharge of water from artesian wells has for many years been employed as a motive power in France. In the city of Tours there is an artesian well which drives a hydraulic wheel 7 metres in diameter, and works the machinery of a silk factory. At Grenelle the heat of the water issuing from a deep well is utilized in warming buildings. A project is now before a Commission of the Municipal Council of Paris, having for its aim the utilization of the power obtainable from the new artesian well in the Place Hébert, at La Chapelle. There are now three important artesian wells in the Paris basin; that of Grenelle being the oldest, and that of Passy the most productive. The new La Chapelle well is, however, situated in an industrial quarter of the Eighteenth Arrondissement; and is thus well adapted for the experiment of producing motive power. Besides these, there are a number of private artesian wells in Paris belonging to manufacturers. The La Chapelle well was finished in March last; having been begun 24 years ago. It reaches a depth of 720 metres, and the water, left to itself, rises to a height of 35 metres above the mouth. It furnishes 6000 cubic metres of water every 24 hours. The proposal is to utilize the power furnished by the well in generating and distributing electricity for lighting and motive purposes. One object mentioned is the lighting of the park of the Buttes Chaumont, which is situated near the well. Before now electricity has been generated in this manner. At Ponce de Leon, in Florida, there is a hotel having a powerful artesian well, which drives a turbine-wheel and dynamo; thus generating the current necessary to light the building and its grounds. At Yankton, in Dakota, there is a flowing well which drives the dynamos of an electric light company. The well is 600 feet deep; and the water on issuing from it is conducted to a reservoir 30 feet above the turbine which is employed to actuate the dynamos.

THE REMOVAL OF HINDRANCES TO THE CONSUMPTION OF GAS.

SIR,—Some of the papers which are read at Gas Association and other meetings, and afterwards printed in your columns, with reports of the discussions which arise thereon, must be most perplexing to many of your readers, owing to the different and various methods in force under respective Gas Authorities. I refer particularly at present to the payment of deposits, the rent charged for meters and gas-stoves, and the cost of laying service-pipes. There is evidently no uniformity whatever in dealing with any of these matters either in Corporations or Companies; and it is probable that the practice of no two Authorities is alike.

As to the question of deposits. In some towns the rule seems to be to require deposits from all consumers, with exceptions under special circumstances. In other places this rule is exactly reversed; no deposits being required, except in certain well-defined and special cases. It will be manifest, therefore, that any discussion of the subject without this previous explanation as to custom must be pointless and unsatisfactory. I submit that the payment of deposits under the latter rule is perfectly justifiable. The profit arising from the consumption of gas in these special cases, without a deposit, would be more than swallowed up by bad debts. Increase of business may be had at too great a price; and on these terms it is certainly not desirable.

As to the question of charging rent for gas meters and stoves, we are again met with differences in practices and circumstances. In some large towns, many persons prefer to hire their meters or stoves; while a large number prefer to purchase one or both. How are the owners of meters and stoves to be dealt with equitably, if and in case the Corporation or Company decide not to charge meter or stove rents in future? It is contended by some persons that the initial price of gas ought to cover *all cost*, including meter and stove rents, service-pipes, and some internal fittings; but I fear that the proper re-adjustment of the present state of things to the new conditions which would arise when these charges cease to be made would be very difficult, if not altogether insurmountable.

In some towns I understand, it is not the custom for builders or owners of houses or other premises to lay any piping or to supply or fix any internal gas-fittings whatever; whereas, in other places—especially in large towns—the reverse is again the custom. Piping is almost invariably laid to the principal living and bed rooms, and most of the common brackets are also fixed, and in some cases chandeliers and brackets complete. The cost of doing all this is included in the rent of the house; and this to me seems a fair and reasonable arrangement. As well might the price of candlesticks be charged in the price of candles, as the cost of gas-fittings be charged in the price of gas. Such fittings, however, when provided by the owner of a house, become fixtures; and their cost may legitimately be provided for and included in the rent, as in the case of other fixtures.

I do not know what the custom is as to the charge made for service-pipes. In the large town from which I write, the custom is to make no charge at all, except for so much of the pipe as is required to be laid through private property—such as the small gardens or courts in front of houses or other premises through which the pipe has to be taken.

I apprehend that much of the difference in procedure to which I have referred, arises from the different circumstances in which towns are placed as compared with one another; and especially to the fact that, in small towns, the whole of the consumers (and much in relation to their circumstances) are personally known to the gas officials, which is utterly impossible in large towns. Further, that the working-class inhabitants of the smaller towns are much less migratory than those of the larger towns; hence the necessity for more stringent rules in the one case than in the other.

My object in writing is to urge that gentlemen who read and discuss papers on these subjects, and such as these, should let it be clearly known what they really mean and what they condemn or approve.

Dec. 20, 1888.

THE POSITION OF GAS ENGINEERS.

SIR,—As Manchester has figured rather prominently in this discussion, I should be glad if any of your readers could inform me whether the rumour be true that the Bradford Road works—which were erected from designs selected and approved by Messrs. Hawksley, Livesey, and King—have already cost the Corporation of that city a sum of between £400,000 and £500,000, upon a large portion of which commission was paid, in addition to the £1500 mentioned by Mr. Livesey as the cost of the preliminary advice. Also whether the manufacturing and storage capacity represented by that outlay is regarded as so insignificant as to be sufficiently looked after by a Foreman acting under the supervision of the Resident Engineer of another works at a distance.

Dec. 21, 1888.

ENQUIRER.

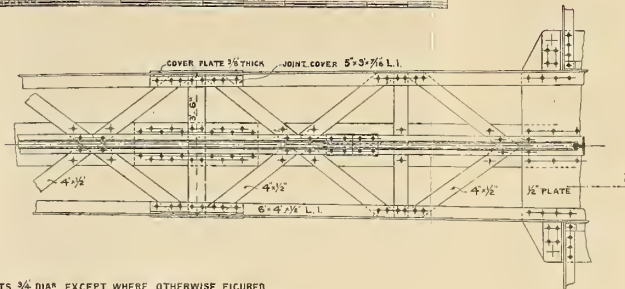

SERIOUS COMPLAINTS AGAINST THE QUALITY OF YEADON WATER.—At the last meeting of the Yeadon Local Board, Dr. Usher attended, and said that as a medical man he had felt it his duty to come before the Board to lodge a complaint against the Yeadon Water-Works Company. It was purely out of regard for the health of the people of the township that he attended. He had discovered that the Company were allowing a very large portion of their gathering-ground to be manured. The night-soil was of the very worst character; and a portion of it was spread, while the other portion was in lumps. Some of the manure was even spread over the pipes which, without any filtration whatever, conveyed the water to the consumers. This was a very demoralizing, filthy, and disgraceful piece of business; and he could not speak too strongly about it—more especially as he had previously had to complain about the very same thing. As there were infectious diseases in the immediate district, it was important that the Board should take the matter in hand immediately. The speaker produced a sample of water (taken from a tap at the top part of the town), which was of a very black and sludgy character. Mr. Smith, one of the members of the Board, said he had himself seen the manure being put on. On the suggestion of Mr. Lees, a Committee of the Board were appointed to view the alleged nuisance.

YORKSHIRE AUTUMN ASSIZES—WEST RIDING DIVISION.
LEEDS TOWN HALL.—TUESDAY, DEC. 18.
(Before Mr. Baron POLLOCK.)

THE CHARGE AGAINST MR. WILLIAM CARR.

To-day, Mr. W. Carr, the late Manager of the Halifax Corporation Gas-Works, surrendered to his bail to answer the charges preferred against him, at the instance of the Corporation, of fraudulently taking certain leaves from a letter-copying book belonging to that body. There were three counts in the indictment—viz., (1) That on the 28th of September, being a servant of the Corporation, the defendant feloniously stole 79 sheets out of a foolscap press copying-book; (2) That, being the Gas Manager, he mutilated the book by abstracting the leaves; and (3) that, being a public servant, he committed the same act. To all the charges Mr. Carr pleaded, "Not guilty."

Mr. TINDAL ATKINSON, Q.C., with Mr. BANKS appeared for the Corporation; Mr. WADDY, Q.C., and Mr. KERSHAW represented Mr. Carr.

Mr. ATKINSON said the indictment was preferred under an Act of Parliament which made it a felony for anyone in the position of a servant to mutilate, destroy, or falsify, with intent to defraud, any book or document belonging to his employers. The facts he should lay before the jury would, he thought, satisfy them that a book which belonged to the Corporation was undoubtedly mutilated by the prisoner; and he expected that the real question which they would have to deal with would be the intent with which this was done.

Mr. WADDY said that was so; and that had all along been the question.

Mr. ATKINSON thought the facts would satisfy the Court that prisoner was actuated by the intention either to actually defraud the Corporation, or, what was quite sufficient in point of law, to prevent further enquiry. The prisoner was appointed Gas Engineer and Manager to the Corporation as far back as the 2nd of June, 1875. His salary which at that time was £250 a year had increased at the time he sent in his resignation, on the 12th of September last, to £500 per annum. His duties were not defined by the resolution which appointed him; but the duties that he did carry out included those of the general superintendence of the production of gas, and of Gas Engineer to the Corporation. It was his duty when contracts were entered into from time to time for coal to be used for gas making, to make tests of the character and quality of the coal, in respect of the illuminating power of the gas to be obtained from it, and also with regard to the value of the residual products and the quality of the coke. The instruments by which the tests were made were the property of the Corporation; and the salary which the prisoner received was in consideration of the duty of making the tests as well as of other duties which he had to perform. In May last, 13 tenders were sent in for coal required by the Corporation during the year 1888-9. Six of these were from firms from whom the Corporation had previously had coal; and in respect of this coal tests had been made by the prisoner, and should have been in his possession at that time. These tenders we partly accepted at a meeting of the Gas Committee on the 18th of May. There were seven other tenders from firms whose coal had not up to that time been accepted; and the Committee instructed Mr. Carr to make tests, to ascertain the character and quality of this coal. The tests were made; and the document in which they were entered was in the hands of the prisoner on the 1st of June, when an adjourned meeting of the Gas Committee was held to consider the results of the prisoner's investigations. He should show that the prisoner—being a skilled person and understanding the duties of his office—was practically responsible for the acceptance of the tenders. Though the Committee, of course, nominally made the selection, he undertook the investigation into the quality of the coal, and his opinion and his judgment governed the Committee. He was therefore the person really responsible for the selection of the tenders, which ought to have been those for coal which in his opinion would be the best for the purpose for which the Corporation required it. At the meeting on the 1st of June he called the Committee's attention to the results obtained by his tests; and upon his recommendation, from out of the seven lots of coal, four were selected as coal which should be contracted for. In that same month of June the Mayor or the Town Clerk received a letter from a person named Ellis Lever, which he (the learned Counsel) was entitled to refer to, because he had evidence that it was laid before the prisoner and his attention was distinctly called to it. That letter was dated May 22; and he proposed to read it.

Mr. WADDY did not understand how this was to be made evidence. It was a letter from a person named Lever, who had no connection with this case, and it was to be made evidence, without calling the writer, because somebody had said to defendant "here is a letter from someone."

His LORDSHIP did not see how a letter written by someone to the Town Clerk could be evidence unless the writer came to prove it, or it was shown to the defendant in the course of the enquiry.

Mr. ATKINSON said he was in a position to prove that it was shown to the prisoner.

Mr. WADDY remarked that if that was so, and if his client made any remark upon the letter, he should offer no opposition to its production.

Mr. ATKINSON: I am going to show that the letter was laid before defendant, and that his attention was called to the charges in that letter and in the *Pall Mall Gazette*.

Mr. WADDY: Then I venture to say that that could not be evidence; and that anything more improper on the part of these people cannot be conceived. This gentleman was challenged to bring an action; and was told that if he did not do so, he was to be held to be guilty.

His LORDSHIP pointed out that there were two ways in which the letter could be made evidence. If it was brought before the Committee while the prisoner was present, it would be part of the transaction; and it would also be evidence if his attention was called to it and he was asked to make an explanation.

Mr. ATKINSON said it was actually before the Committee while the prisoner was present.

His LORDSHIP said he could not say it was not evidence; though how it might effect the prisoner he could not say.

Mr. WADDY: The result will be and I venture to say it is what is intended, that any articles however scurrilous written by the *Pall Mall Gazette*, or any other newspaper, may be read here to prejudice the prisoner. The only notice we have received of these letters is this "At the time these tenders were under consideration by the Gas Committee two letters were read, one from Mr. Ellis Lever and the other from Mr. T. K. Fox."

His LORDSHIP: Haven't you had copies of them?

Mr. WADDY: No; and it does not say they were laid before the defendant.

His LORDSHIP: In one sense his attention was called to them; he ought to know of them.

Mr. WADDY: Yes. He was challenged to bring an action, though they

had got the opinion of a learned friend of ours that such an action would not lie.

Mr. ATKINSON: No, no; that is not the point. We have given notice to admit these letters, and no application has been made for copies of them. The Solicitor on the other side has actually inspected them.

Mr. WADDY: Was that after you stormed his office?

Mr. ATKINSON: I don't know; but he has seen them.

Mr. WADDY said he would leave the matter in the hands of the Court.

His LORDSHIP said it was unfortunate that the prisoner should not have had the fullest opportunity of inspecting the documents; but he could not say they were not evidence.

Mr. ATKINSON then proceeded to read the letters. The first was dated, Colwyn Bay, May 22; it was from Mr. Ellis Lever and was as follows: "I am in receipt of your circular letter of the 19th inst., informing me that my firm's offer of cannel has been declined by the Gas-Works Committee, which, with the information in my possession, does not surprise me. In the interests of fair and honourable trading, as also of the ratepayers and gas consumers of Halifax, I must ask you for an appointment, to enable me to show you how the Committee have been dealt with in the past." On June 3, the Town Clerk received the following letter from Mr. T. K. Fox, of the Silkestone Coal Company: "I wish to know why my firm were not asked to send sample trucks of gas coal, as resolved by the Committee. Our tender has been declined without giving the coal a trial; and I am confident the material we offered is worth far more than some of that you have purchased. It is not in the interest of the Corporation that the ratepayers should not have the best value for their money; and the Halifax Corporation will be well advised to inquire into the charge I make before putting their seal to any contracts. I am informed on very good authority that one man has an interest, directly or indirectly, in many contracts with the Gas Department of the Corporation of Halifax; and it would be well that this matter should be sifted to the bottom. Halifax cannot desire a repetition of the Salford scandal." Then, continued the learned Counsel, on the 7th of June, an article appeared in the *Pall Mall Gazette*—

His LORDSHIP (interrupting) asked how it was proposed to bring that in as evidence.

Mr. ATKINSON said the article was brought to Mr. Carr's attention; and he was called upon—an indemnity being offered him—to meet the charges suggested in the letters and the article by an action brought for the purpose of clearing himself.

Mr. WADDY remarked that the charges, whatever they were, were not before the Court in this case.

His LORDSHIP said that was so. The prisoner was not charged with conspiracy, but with mutilation of the books.

Mr. ATKINSON said the essence of the charge was fraud.

Mr. WADDY observed that at the time these letters and articles were written, the mutilation of the book had not taken place.

Mr. ATKINSON said that was surely not the point. Fraud might exist before mutilation, and the mutilation would take place afterwards for the purpose of covering the fraud.

His LORDSHIP: All this only goes to prove a wider range of misconduct on the part of the defendant.

Mr. ATKINSON replied that they had to deal with the question of the intention to defraud. There was no doubt about the mutilation; and the sole question was as to the intention with which the mutilation took place.

His LORDSHIP said he could not shut the evidence out if he was told that it was necessary; but it was very unlike an ordinary proceeding in a case of this kind.

Mr. WADDY observed that not one particle of this evidence was gone into before the Magistrate.

His LORDSHIP: It is very unfortunate that the case should assume such a position. This is practically a new case; there can be no doubt about that.

Mr. ATKINSON remarked that these matters had been before the prisoner from the time they were written. He then went on to read from the *Pall Mall Gazette* article headed "Corrupt Practices in the Gas Industry;" which was as follows:—"The existence of corruption in the gas industry has been sufficiently demonstrated by the notorious Salford case; but whether it is the laggard way in which that criminal has been treated, or that the evil is too deeply seated, it does not appear that there has been any change for the better. Similar charges have been brought against officials in other towns."

His LORDSHIP (interrupting): No, surely.

Mr. ATKINSON then passed at once to the last sentence of the article—"We should hear shortly of disclosures at Halifax if the parties concerned dare to court inquiry"—and said he should prove that the prisoner's attention was called to these charges, and, further, that the Mayor (Mr. Booth) offered him an indemnity if he would bring an action against the *Pall Mall Gazette* in reference to the insinuation in that article, calling attention to frauds in another Corporation, and suggesting that there might be disclosures of the same kind at Halifax.

His LORDSHIP said a criminal intent could not necessarily be assumed from a refusal to take such a course. It was a new thing to throw a newspaper article at a man and say "Unless you bring an action you must resign."

Mr. WADDY: The Corporation were advised by Mr. R. S. Wright, whose opinion they took, that an action would not lie.

His LORDSHIP said the case, as he understood it, was a very simple one; and he deprecated the introduction of outside matter. It was alleged against the prisoner that, having received certain tenders, and made certain examinations of the tenders by way of testing the coal, and the Committee having accepted certain of the tenders, he then destroyed the evidence as to whether or not the tenders accepted were the most advantageous. What this meant was that, after having made analyses of the coal offered to the Corporation, he knowingly selected the worst class of coal; and then to cover the fraud on his part he mutilated the book. That was really the question. It was a case within a small compass; and none of the sort of evidence that had been alluded to ought to affect it. What he meant was that, if the Corporation's case was a good one, it did not need this general surrounding. It was a clear charge against the prisoner to be supported by evidence.

Mr. ATKINSON said what he had mentioned was not perhaps his strongest evidence. Some of the sheets from this book had been destroyed; and some they had in their possession. The question the jury would have to decide was what was the intention of the prisoner in taking these leaves out of the book. If he established the fact that distinct charges were formulated against the prisoner, that it was stated in his presence that he had received money which belonged to the Corporation and kept it for his own use, and that when he was alleged to have been guilty of malpractices in connection with his profession, he declined to bring an action, he submitted that this would be evidence to go to the jury.

His LORDSHIP said all that was brought to the prisoner's knowledge was essential to the issue; but it did not follow because an article appeared in a newspaper that a man was bound to take one course or another.

Mr. ATKINSON repeated that he had stronger evidence bearing on the matter.

His LORDSHIP said that what had been advanced might be important evidence; but he wanted to know what the facts were, and whether there were fraudulent acceptances of tenders.

Mr. ATKINSON explained that he was dealing with these matters in order of date. These were circumstances before the actual discovery.

His LORDSHIP: Yes, before discovery; but, as he understood it, the prosecution said that before this meeting on June 1, the prisoner must have been guilty of accepting contracts that were against the interests of the Corporation.

Mr. ATKINSON said that was what he intended to prove.

His LORDSHIP said it was impossible to always tell what men would do when charged with dishonesty. Some took a sort of wilful course, and said: "I know I am honest, and I shall not take any action." It was probable that others would take a different course; but the inference to be drawn in either case was not important. This was a criminal action; and there must be proof for every allegation. Evidence should first be given that the defendant behaved dishonestly in not accepting certain tenders; and then that he destroyed the evidence of this by taking the leaves from the book.

Mr. ATKINSON said he would pass on at once to disclose what was discovered of the prisoner's conduct after the Corporation got possession of the leaves which contained tests of coal undoubtedly accepted by him. On the 12th of September prisoner resigned his position as Gas Engineer to the Halifax Corporation. On the 27th of September a letter was written to him by the Town Clerk asking for the production of the tests laid before the Committee on the 1st of June—viz., the tests with regard to the seven tenders specially referred to him. These tests were in the prisoner's possession at that time (the 27th of September), or ought to have been, because in June he went to the Town Hall and asked for them, saying he had left them on a desk. A clerk would tell the Court that he handed the tests to the prisoner at that time. On the 27th of September prisoner wrote, in reply to the application of the Town Clerk, that he had not got any of these tests. That was untrue; and it would prove to be untrue. The reason why he denied the possession would become obvious when he mentioned the subsequent fact. Subsequently a book was discovered in which entries had been made, by direction of the prisoner, of tests which had been taken from time to time by the prisoner with reference to the coal supply of the Corporation. That book was in a mutilated condition—no less than 79 pages having been torn out of it. Inquiries were made; and it was discovered that on the day on which the prisoner received the letter from the Town Clerk asking for these very tests (made between May 18 and June 7), he had directed a clerk named Milner to tear from the book everyone of the pages which contained records of tests. Proceedings were then taken against the prisoner; and he was brought before the Magistrates.

His LORDSHIP: Were these leaves given to the prisoner?

Mr. ATKINSON: Yes; the clerk handed them to him. When prisoner was before the Magistrate a number of documents were produced in Court, which apparently included the leaves torn out of the book. Some of them were shown to the witnesses called on the part of the prosecution; and it was suggested that they were perfectly harmless because they contained tests of coal sent to him by private individuals (although he was a servant of the Corporation) in order that he might test it. The Corporation were not satisfied with that. They obtained a search warrant, which was executed—it was an unfortunate fact, but must be mentioned—on the premises of the Solicitors for the prisoner. Here 67 of the missing sheets were recovered. It was suggested that they were private tests; but it was discovered that 44 of them represented tests made by prisoner of coal which had been the subject of contract by the Corporation. They were therefore clearly documents belonging to the Corporation, affecting the Corporation business, and ought undoubtedly to have been left in the book. These tests had been submitted to persons skilled in these matters; and the results had been compared with the contracts which had been accepted by the prisoner on behalf of the Corporation, and with the coal rejected by the prisoner as coal not fit for the purpose for which the Corporation required it. The result was that in a number of instances coal which was tested by the prisoner—the tests being contained in these sheets—was found to be quite inferior to other coal which was tendered at the same time; and the inferior coal, or rather the coal at the higher price, had been accepted by the prisoner, and that which would produce better results, at a lower price, had been rejected. That was not a solitary instance—it had been done again and again—and the loss to the Corporation would be proved to be enormous. He might suggest the purpose which the prisoner had in view; but it would present itself to the minds of the jury. He had already said that in May there were thirteen tenders, of which six representing coal previously tested were accepted; and of the remaining seven tests were ordered to be made. In the six there was a tender from the Mirfield Coal Company, who offered 10,000 tons.

Mr. WADDY objected that no notice of this had been given to the defendant. A list containing the analyses of three kinds of coal was supplied; but the Mirfield Coal Company was not one of them. The three mentioned had been submitted to the analyst, who would be called for the defence; but they had had no opportunity of testing any statement as to the Mirfield Coal Company.

His LORDSHIP: I never blame people unless I know the whole of the facts, and I suppose the Corporation in this case found out their facts at the last moment. What takes place before the Magistrates may be only preliminary to what may be afterwards found out and laid before the jury; but when it is a matter which requires investigating, like an analysis, the prisoner should have ample notice.

Mr. ATKINSON said he had other cases in which undoubtedly notice was given. Amongst the thirteen tenders there were three—viz.: Milnes, Stansfield, and Co., who offered 10,000 tons; E. Lister Kaye, 10,000 tons; and Newton, Chambers, and Co., 10,000 tons—

Mr. WADDY: The analyses of the two former were completed and reported upon before the third offer came.

Mr. ATKINSON: I shall prove that the tenders were all sent in at the same time.

Mr. WADDY: Of these two, one report was made and the coal bought before the test of the other was made.

Mr. ATKINSON: I am instructed that the Council had not ratified these contracts before the tests had been made by the prisoner.

Mr. WADDY: But the purchase had been made by the Committee. How can it be said that there is any fraud, any preference one over another, when the one is done and finished before the other is heard of?

His LORDSHIP: They were not opened at the same time?

Mr. ATKINSON: I am told all tenders were opened at the same time.

His LORDSHIP: The parties should know what is in agreement between them. It is very inconvenient to turn this Court and jury into a committee of inquiry into everything that can be said in this matter.

Mr. ATKINSON: There is considerable difficulty in the case, arising out of the length of time over which this extends. My learned friend says

that these three tenders cannot be brought against the prisoner, because in reference to two of them the contracts were made before the other was considered. That will, however, arise upon the evidence rather than upon my opening.

His LORDSHIP: I don't think it necessary you should prove the actual contracts. It is a question after all of the motive of the prisoner. If the prisoner did fraudulently manipulate the contracts, and rejected the good and accepted the bad, that is an element in the case. Is there any evidence that he had any interest in any of these?

Mr. ATKINSON: We can't prove it; we say it is an inference arising from the facts.

His LORDSHIP: Have you any evidence of corrupt motive?

Mr. ATKINSON: No, my Lord.

His LORDSHIP: You simply say that rejecting the good and accepting the bad is evidence enough of motive?

Mr. ATKINSON: Yes, my Lord, and the destruction of the documents.

His LORDSHIP: That I mean—motive for the destruction of the documents. Do you know the nature of the documents destroyed?

Mr. ATKINSON: Yes, they were recovered.

Mr. WADDY: Seventy altogether, including the three attached to the depositions.

Mr. ATKINSON said he was telling the jury that three tenders were sent in. That of Newton, Chambers, & Co. was for 40,000 tons at 7s. 9d., Milnes, Stansfield, & Co., and E. Lister Kaye, 10,000 each at 9s. 2d.—a difference between the two latter and the first-named of 1s. 5d. per ton. The tenders of Milnes, Stansfield, & Co., and E. Lister Kaye were in the six accepted by the Gas Committee on May 18; and on the same day tests were ordered to be made of the coal of Newton, Chambers, & Co. The tests in the latter case were favourable; and having got them in his hands, it was the duty of the prisoner to inform the Council, before the other contracts were ratified, that Newton, Chambers, & Co.'s coal was equal in quality to the other, and advise them to accept the tender of 40,000 tons, in place of that which he did advise them to accept.

His LORDSHIP: But I understand that, in the cases of Milnes, Stansfield, & Co. and Lister Kaye, the tenders were accepted.

Mr. ATKINSON: Yes.

His LORDSHIP: Then you must compare Newton, Chambers, and Co.'s coal with the offers open at that time; that is to say with existing offers, and not with existing contracts.

Mr. ATKINSON: What I submit is that they were all open.

His LORDSHIP: Yes, in one sense.

Mr. ATKINSON: We are dealing with the conduct of the prisoner. The contracts had not been accepted in the sense that they were accepted by the Corporation.

His LORDSHIP: Yes; but suppose for a moment that the prisoner had, carelessly or otherwise, accepted contracts from Milnes, Stansfield, and Co., and the other firm, which he found afterwards were not absolutely the best, it would be rather curious if they found themselves ousted after their tenders were accepted by the Committee.

Mr. ATKINSON said the tenders had not been accepted so far as any communication between the parties.

Mr. WADDY: They had sent circulars round to those who tendered.

His LORDSHIP said he was trying to arrive at what would be the conduct of the prisoner under the circumstances.

Mr. ATKINSON said the result to the Corporation was serious, because the loss to them would be about £1000.

His LORDSHIP: What I am trying to balance in my own mind is this: Here is a person against whom a criminal charge is made. He has accepted these two tenders—I mean he has forwarded them to the Committee, and the Committee have voted on them and adopted them; and then, after all, there comes this information. If this had been an action for discharging him for unbusinesslike qualities, I could have understood it; but to make it the foundation for a criminal charge is going a very long way. However, that is for the jury.

Mr. ATKINSON: What the Corporation say is that, when he got these tests, it was his bounden duty to call attention to them.

His LORDSHIP: The charge against him is not of rejecting this and accepting the other, but of mutilating the books. You say this is evidence of guilty knowledge in mutilating these books.

Mr. ATKINSON: Yes, my Lord, it is incidental yet necessary.

His LORDSHIP: I thought you had had a much stronger case—a case in which A. and B. both tender, one is clearly the better coal, and the other is clearly the worse; and he accepts the worse and rejects the better, and then, in order to hide that, he destroys the books. If you have a case like that, it would be another thing.

Mr. ATKINSON said he had such a case in the one which Mr. Waddy objected to—the Mirfield Company's case.

His LORDSHIP: And in that you have not given notice. There was an abstract opinion that no man should ever do anything but what was best for his employers. But suppose a man made the best contract he could at the time, and before it was sealed or signed a better offer turned up, was he bound to reject the first? Take an ordinary case in life. A man sent his servant to buy the best wine he could at a certain price. One wine merchant offered him wine at 20s. a dozen and another at 25s. a dozen. The latter was the worse, but he took it because the merchant gave him 4s. or 5s. a dozen for his own pocket. In that case, there was a clear act of dishonesty. But suppose the employer sent him to a certain place to buy wine, and he was on his way to buy it when he heard of a better offer. He did not think that in that event a jury would convict him of dishonesty because he did not go back to his master and make a fool of himself and the other man.

Mr. ATKINSON: But suppose the master before concluding his bargain with the first sends him to another man?

Mr. WADDY said his friend would find that the test in the Mirfield Company's case was not made at the same time as the others, but, as a matter of fact, was made so far back as March 3, 1879.

Mr. ATKINSON remarked that he did not care about the date of the test.

Mr. WADDY said the Company had supplied a stated quantity of coal for several years.

His LORDSHIP: Well, I am afraid I cannot say any more; but I think it is a pity that we cannot get at the real issue. One ought to have some exact definition of the charges.

Mr. ATKINSON, continuing his address, said the fact of the mutilation of the book was practically undisputed. He was prepared to prove that on the 27th of September he denied all knowledge of the tests.

Mr. WADDY: No; read the letter.

Mr. ATKINSON said he, at all events, denied that he had them in his possession, and the fact that they were after that taken from the book, if it stood alone, should be sufficient to lead the jury to the conclusion that there was a purpose in abstracting these documents.

His LORDSHIP: How came it that notice was not given of this Mirfield case?

Mr. ATKINSON was unable to say.

Mr. WADDY: I don't object to you going into the Mirfield case. I am prepared to answer all things said in the hearing of the jury.

Mr. ATKINSON said he should prove that the test of Newton, Chambers, and Co.'s coal had been made by the prisoner; and it was one of the tests which were missing. It was found on inspecting the sheets, that only two out of the seven tests were still in existence. Where the five had gone the prosecution did not know. They had, however, obtained from Newton, Chambers, and Co. some coal of the same quality as was submitted to the prisoner, and the result of a test of this was to show that their coal at 7s. 9d. per ton was practically equal in quality to the coal supplied by Milnes, Stansfield, and Co. at 9s. 2d., and nearly equal to that of Lister Kaye. There was therefore a loss to the Corporation in the first case of 1s. 5d. per ton; and, as the coal of Lister Kaye was only worth to the Corporation 8s. 6d. per ton, there was a loss in that case of 8d. a ton. The total loss was about £1000 on these two contracts. Milnes, Stansfield, and Co. tendered for 10,000 tons, all of which was accepted; Newton, Chambers, and Co. tendered for 40,000 tons, of which 1500 tons only were accepted; and E. Lister Kaye tendered for 10,000 tons, of which 8000 tons were accepted. In the case of the Mirfield Coal Company, 10,000 tons were offered at 6s. 5d. per ton; but its value to the Corporation, as shown by the prisoner's own test, was 9s. 5d. per ton, and the Corporation would have gained 3s. a ton had that tender been accepted.

His LORDSHIP: Is there any evidence on that on the other side?

Mr. WADDY: I have no evidence—the matter has been sprung upon us—unless I can call the prisoner himself.

His LORDSHIP: said it was a pity the matter had not been raised. The proper course would have been to have a Committee to inquire and report; and upon that report an indictment might have been framed. The prisoner was there to meet certain charges; and they were entering into a criminal inquiry. Was it not possible now to adopt some course so as to put the case in such a shape that the issue might be tried? The prisoner's character ought not to depend upon an accident, nor yet ought the case for the Corporation.

Mr. WADDY remarked that it was impossible to enter a criminal case for trial elsewhere.

His LORDSHIP said if he had known of this difficulty while sitting at Pontefract, or somewhere else, he should have suggested that the case might stand over for the purpose of inquiry.

Mr. WADDY: That would be a terrible thing to do now.

His LORDSHIP: Of course, the defendant comes here to meet the case.

Mr. WADDY: If any civil charge had been made against my client, he would have met it with the greatest readiness.

Mr. ATKINSON: He had ample opportunity.

Mr. WADDY: That I absolutely deny; and it is contradicted by the letters.

His LORDSHIP said this was not a civil case; and it was obvious to everybody that a case of this kind ought to have been most accurately formulated. No doubt the Corporation had done its best; but before the indictment was absolutely framed and sent up to the Grand Jury, it would have been wiser that something further should have been done. Let them just remember what would happen at every stage. The Jury would have to consider the difference between these facts—the difference in the contracts, the state of the market, the illuminating power of the gas and all these things they must be thoroughly convinced upon before they decided one way or the other. Whether the prisoner could account for the thing honestly, or whether he removed the records in order to cover up some previous sin, would have to be considered. Whether there was a previous sin or not depended entirely on the whole question of the tenders, on the value of the different calculations made upon the analyses, and of the truth also or the accuracy of the estimate as to the market value of the coal and the particular value of it to the Corporation.

Mr. ATKINSON said the difficulty was that it was not until after the commitment of the prisoner that the Corporation could obtain the books; so the evidence could not be given before the Magistrates. The tests had to be submitted to skilled witnesses, and it was only at the very last moment the Corporation had formed any opinion of the character of the tests.

Mr. ATKINSON said his friend was entitled to deal with the fact that they had not supplied particulars as to the Mirfield Coal Company.

Mr. WADDY said that if his learned friend would hand him the analysis in the Mirfield Company's case, he would not complain.

His LORDSHIP, speaking to the jury, said the question to which they were to address themselves was, assuming that the defendant did destroy certain books, did he do it with a corrupt motive. If he did these things carelessly, or even improperly in one sense, he would not be committing a crime. The first question was, What was his object in doing this? In order to arrive at that, they must inquire into all these points.

Mr. ATKINSON said there were only four tests with which he would trouble the jury. The Mirfield Coal Company tendered 10,000 tons at 6s. 5d., which was worth 9s. 5d. The test of that coal was in the possession of the prisoner, for it was on one of the sheets which had been recovered. It was true it was an old test, made in 1879; but the prisoner knew the result of the test, and the value of the coal to the Corporation. The tender of Milnes, Stansfield, and Co. was accepted, for 10,000 tons, though the price was 9s. 2d. and the value only 7s. 9d.; but not a single ton was ordered from the Mirfield Coal Company, though the price was only 6s. 5d., and the value 9s. 5d. The evidence which would show this to the Corporation was the tests which were in the book; but when the prisoner found that inquiry was being made for them, he ordered his clerk to tear out, not only the seven tests, but every test contained in the book from 1879 to 1888. It was impossible for the prosecution to prove what pecuniary object the prisoner had, if he did do it, in advising the Committee to pay a higher price for their coal than they could have got it for. When a man was asked to produce a book or a document belonging to his employers, he did not immediately proceed to destroy it, or tear leaves from it without he had some strong motive, and unless some explanation were offered, the inference was irresistible. When asked on the 27th of September for these tests, he wrote back to say that he did not possess them. He (the learned Counsel) would show that that was absolutely true.

Mr. WADDY objected that no notice was given his client to admit the letters.

Mr. ATKINSON read the correspondence which took place on the 27th of September between the Town Clerk and Mr. Carr. The Town Clerk asked for the tests referred to in Mr. Carr's report of June; and Mr. Carr replied that he had not seen them since they were submitted to the Committee, and was under the impression that they were taken possession of by another official, as they related to contracts which were accepted. That statement was untrue; and it was the strongest testimony the jury could have against the prisoner.

James Milner, Chief Clerk in the Halifax Corporation Gas Department, was then called on behalf of the prosecution. In answer to his LORDSHIP and Mr. BANKS, he said he recognized the foolscap copying-book produced. It was used for the purpose of having reports of different kinds copied into it. There were seventy-nine sheets missing from the book. About the 28th of September he tore out the leaves, upon being asked by the prisoner to take the coal tests from the book. The book was kept in Mr.

Carr's office. He could not say why the prisoner asked him to take out the tests. The sheets contained copies of coal tests which had been made by the prisoner. The documents were copied consecutively. He simply took out the sheets when he was told to do so. He did not know whether sheets had been taken out of the book before he took these out or not.

Mr. WADDY: You are the Chief Clerk. Is there anyone in the gas-works who knows more about them than you do?

Witness: I do not know; there may be, or there may not.

His LORDSHIP: You must know if there is.—No, in my department there is not.

By Mr. WADDY: He could not tell whether the test of the Mirfield Company's coal in 1879 was of screened or unscreened coal. It would make a deal of difference whether it was screened or unscreened; but he could not tell whether the sheet produced gave the result of one or the other. He did not know whether the Mirfield Company really supplied screened or unscreened coal.

Mr. ATKINSON said that the tender was for "coal such as previously supplied."

Mr. WADDY: Is it not a fact that the coal actually supplied was unscreened?—I don't know.

Is there any human being that does, except the prisoner?—Yes.

Who?—The man's dead.

In answer to further questions, witness said he copied the coal tests made by Mr. Carr to lay before the Committee. They were different in form from those produced. In none of those produced was there any money value given; but in the tests laid before the Committee, the money value was worked out and stated. He did not, to his knowledge, tear any tests of that character out of the book. The earliest record in the book was dated February 1876; and he had been the person who copied the various documents into it. He had spoiled some pages and torn them out from time to time.

Mr. WADDY: Am I right in saying that that may have happened eight or nine times?—I could not say.

Didn't you tell the Magistrates it may have happened eight or nine times?—Yes, I did. He could not say that every sheet except those he so destroyed had been recovered; but he would not venture to say it was not so.

His LORDSHIP: Nine may be accounted for in that way?—Yes.

His LORDSHIP: That simplifies the condition of things.

Mr. WADDY: Do you know as a matter of fact that Mr. Carr was in the habit of making analyses for other engineers, for which he was paid, altogether apart from his business.—I know he has made tests.

Don't you know that vendors of coal were in the habit of getting his analysis for the purpose of putting it out with a view of getting customers?—I can't say that.

His LORDSHIP: You never saw them alluded to in advertisements of excellent coal analyzed by Mr. Carr?—Not in that way. I have seen the analyses in print in the form given on pages taken out of the book.

Mr. ATKINSON, in reply to his LORDSHIP, said some members of the Corporation knew that Mr. Carr made these private analyses; but the Corporation as a whole did not know. Forty-four of the tests produced related, however, to coal tendered for to the Corporation.

Mr. WADDY said this was the first time any objection had been hinted against the prisoner's private practice in that way. He asked the witness if it was not true that on one occasion Mr. Carr sued a man in the County Court for his fee of £5 5s., and called a member of the Gas Committee as a witness in support of his claim.

Witness said he had no recollection of this matter.

Mr. WADDY: I ask you, sir, the Chief Clerk, to tell me of one single case in which you undertake to say that the Corporation have lost money by this man? I give you the whole range of the thirteen years.—It is a thing which I have no knowledge of at all. I don't know.

Now, I will carry it further. Don't you know that, with regard to these private analyses which this gentleman made, the fact was that coal was sent to him, sometimes a considerable quantity (a ton at a time), that he used what he wanted for the purpose, and then always made the Corporation a present of the balance, and put it on to the Corporation heap?—No, sir, they never came in large quantities like that.

What quantities did they come in?—A box or sack.

As a matter of fact, whatever was the amount, don't you know that what he did not need went on to the Corporation heap?—It did, sir.

Do you also know that when this inquiry, instigated by this man Lever, first began, the Mayor, I think it was, alleged that there were hundreds of tons short?—No, sir, I don't.

Don't you know that he stated it in the Council Chamber coolly?—I cannot say, sir.

His LORDSHIP: One way or the other—you don't know?—No.

Mr. WADDY: Is it not a fact that an investigation was then held, and it was found that, instead of being hundreds of tons short, they had actually got 1200 tons more than they ought to have had?

His LORDSHIP: Do you know that?—Yes, sir.

Yes; you do. There is something you know, then. (Laughter). Speak so that you can be heard. It is a very important thing to hear all that is said.

Mr. WADDY: The corrupt administration of this man (the prisoner) resulted in this, that you had actually got 1200 tons of coal more than you could account for, instead of less as the Mayor said?

His LORDSHIP: He does not know what the Mayor said; and the prisoner is not indicted for stealing coal.

Mr. WADDY: But there has been an enormous amount of prejudice imported into this case. Is it not a fact that the alleged robbery from the Corporation by this gentleman has ended in this—that in his time the gas-rate has been reduced from 4s. to 1s. 9d.?—Yes; I believe it was 4s. per 1000 cubic feet.

His LORDSHIP: That is for the same quality of gas, I suppose?

Mr. WADDY: Yes, my Lord.

His LORDSHIP: Do you make more than one quality?

Witness: Well, of course the quality varies.

His LORDSHIP: Don't say "of course;" I don't know. Of course, it varies every day, according to your ovens and a number of other things. Do you mean to say that it is all of one quality?—For anything I know, the standard is 14 candles.

Mr. WADDY: You try, at all events, to make the same gas as near as you can?—Yes.

And after having reduced the price in that way, there was actually a profit at the first half of this year of £2000. Is not that a fact?—I don't know.

Why, you are Chief Clerk! The books must go through your hands?—No, sir, I don't.

We have seen now what are the kind of analyses that are entered into that book; now, I must ask you, Is it a fact that of those tests which were sent into the Committee meeting not one was ever entered into that book?—Not to my knowledge.

His LORDSHIP: You are sure of that?—Not to my knowledge.

Mr. WADDY: You were the only man that copied them in weren't you?

His LORDSHIP: That is a very important question.—I don't remember ever copying any into that book.

Mr. WADDY: Now, Mr. Milner, you will tell me fairly upon your oath, as far as you know, is it not a fact that Mr. Carr, by your hand, never tore out a single one of those tests belonging to the Corporation?—It is a thing I could not swear, Sir.

You did?—Yes, Sir.

You selected them?—No, Sir, I took them all out.

They were torn out by your hand?—Yes, Sir.

His LORDSHIP: What did he say?—He said "Take the coal tests out."

What did you understand by that?—The whole of them.

Mr. WADDY: You must have looked at them if they were torn out. Now, Sir, upon your oath, did you ever copy into that book one single test meant for the Corporation?—I cannot swear, Sir.

His LORDSHIP: Do you believe it?—I don't think I did.

Mr. WADDY: You don't think you did? Well, do be fair.

His LORDSHIP: We have got a further step; we have got this, that the two tests or analyses were of a different character—one for the Corporation, and this done privately, containing the chemical analysis.

Mr. ATKINSON: A chemical analysis is necessary in each case.

Mr. WADDY: We will have it perfectly clear. As far as you know, the tests for the Corporation, in any stage of them, were never entered into that book?—As far as I know, they were not.

Either in the chemical stage or in any other stage, as far as you know?—No, sir.

Am I not right in this—that when the Corporation wanted a test made, it was always made out on a loose sheet of paper, copied by you on a loose sheet of paper, and sent into the Committee?—Yes, Sir; I made them out on loose sheets.

In further examination, witness said that on Nov. 23, three of the sheets were produced as samples, and the others were admitted to be in the keeping of Mr. Storey. He did not know that Mr. Storey undertook to furnish copies. He did not know that the Town Clerk, having ascertained the luncheon hour of Mr. Storey, took out a warrant and obtained possession of the letters.

His LORDSHIP (to Mr. Waddy): Is it the cruelty of the luncheon time that you particularly complain of?

Mr. WADDY: No, not the cruelty, but the meanness; and, certainly, it is the first time in my experience that I ever heard of such a proceeding as that one solicitor, after asking for documents from another solicitor, should go behind his back and obtain a search-warrant.

His LORDSHIP: Well, that is a bye-issue.

Mr. WADDY: Like a good many others that my friend detained us with this morning.

Re-examined by Mr. ATKINSON, witness said his duties were to keep the carbonizing and other accounts; but all his time was not spent in book-keeping. He had nothing to do with these tests except to copy them. He had no practical knowledge of coal testing except commercially; but he knew these were not tests for the Gas Committee, because they were not in the form in which such tests were made.

Do you know whether any of these were chemical tests of coal which was being tendered to the Corporation? Not that I am aware of.

The question was repeated, and witness gave the same answer.

His LORDSHIP: You may lead the horse to the water; but you cannot make him drink.

Witness explained that, so far as he knew, the tests for the Corporation were only made out for the commercial value, and not chemically. Those for the Corporation never to his knowledge had the chemical part attached.

James Nicholl, Borough Accountant, said that pages had been torn out of the book produced. He had not examined the pages recovered under the search warrant; but had seen copies of them, and made a list of those which he alleged were tests of Corporation coal.

His LORDSHIP: How could he make a list without examining the documents themselves?

At this stage the examination stopped for want of the sheets containing the analyses; and his Lordship said that if it would facilitate the matter, he would adjourn for luncheon. The Court adjourned accordingly. On resuming,

Mr. Nicholl said he had glanced through the lists which had been handed to him. He had not carefully examined them and gone through all the figures.

His LORDSHIP, at this stage, said he could not help feeling that this was really not a case that could be shaped against the prisoner, after the explanations which had been given as to the books. Whether he had been wise or prudent, possibly honest, in conducting the affairs of the Corporation was open to question, but to pitch upon these 70 pages, and say that he took them out with criminal intent was, it seemed to him, now that the books were produced and to a certain extent explained, a matter on which no evidence was possible; and he felt great difficulty in putting the case to the jury. It did not follow that the tearing out of the leaves was a crime.

Mr. ATKINSON said he was placed in a difficulty by the circumstance that the documents which were relied upon only came into the possession of the Corporation recently. He could show that, with reference to the seven tests taken after the 18th of May, only two were to be found, and they were amongst the leaves from the book. That put at rest the fact of all the pages relating to private tests.

Mr. WADDY: If my friend proposes to contradict in this way his own witnesses we shall never be done.

His LORDSHIP: When the jury come to consider the question, how can they say that 68 leaves were torn out with a proper motive, and 2 were torn out with an improper motive?

Mr. ATKINSON said a large number of the tests undoubtedly related to coal not supplied for purposes of the Corporation.

His LORDSHIP: I am quite certain no jury ought to convict, nor ought I to leave it to the jury unless there is some specific reasonable proposition to leave to them. It would not be fair to the prisoner to assume this in any sense.

Mr. ATKINSON said he had indicated the nature of the facts which for the prosecution he had intended to prove. He thought he should have been in a position to prove these facts. A certain number of these tests undoubtedly referred to Corporation coal; not all of them.

His LORDSHIP said the whole force of that was taken away by the evidence that the prisoner did not go and select the 2 which might incriminate himself; but he asked for the mass and got, in a perfectly public manner, the whole 70.

Mr. ATKINSON said he was only endeavouring to discharge his duty, but if his Lordship's view was that he was not entitled to ask the jury to find the prisoner guilty, he should not think it necessary to proceed further.

His LORDSHIP: Not only is that my view, but if this had been an ordinary case between individuals, I should some time before this have said that I did not see my way to leave any case for the jury. Inasmuch as there appeared to be a question of a public scandal, in which some wrong had been done by a public servant, I was unwilling at an earlier stage to

interrupt anything that might throw light on the subject. But the further we have gone, the wider we have got from evidence which incriminates the prisoner; and on the other hand the more clearly do we see that there could be no conviction against him.

His Lordship then directed a verdict of "Not guilty," and Mr. Carr was discharged on all the counts.

HIGHGATE PETTY SESSIONS—MONDAY, DEC. 10.

(Before Mr. BODKIN and a Bench of Magistrates.)

BARNET DISTRICT GAS AND WATER COMPANY v. ALEXANDER.

This was an action brought for the purpose of having the house occupied by the defendant assessed for the purpose of fixing the water-rate.

Mr. BANNISTER appeared for the Company; Mr. W. C. JACKSON for defendant.

Mr. BANNISTER, in opening the case, submitted that defendant had no right to challenge the basis upon which the Company charged for their water, as this question was recently settled in the Court of Queen's Bench, in the case of *Stevens v. Barnet Gas and Water Company*. In this case, the defendant lived in a house at Southgate, which was assessed for the Queen's taxes at £58 a year; but the Company not desiring to have any disputes with their consumers, offered simply to charge for water on an assessment of £50, although they had power to charge on £53. The defendant refused to pay on £50; and consequently it had been necessary to take proceedings. As he had refused the liberal offer of the Company, he should ask the Bench to give them all they were entitled to, by fixing the assessment at £53.

Mr. T. H. Martin, Assoc. M. Inst. C.E., the Engineer of the Company, proved that the defendant received a supply of water from the Company at his premises No. 7, Southgate Villas, New Southgate. The water-rate used to be charged on an assessment of £50; but defendant had refused to pay on that amount. The letting value of the house would be £58 or £60 per annum.

Mr. Venables, auctioneer, said that he had seen the house, and considered its letting value was from £55 to £60 per annum.

Mr. JACKSON said Mr. Alexander had occupied his present house since 1882. He took it on a three years' agreement, at £50 a year, and had remained as a yearly tenant at £50; but he was now in negotiation with his landlord for a reduction. There was a gentleman present who occupied a similar house opposite the defendant's, and who was only paying £40 a year rent; and he recently bought his house in the open market for £400. The ground-rent was only £5 10s. In 1886, Mr. Alexander wrote to the Company saying he found that his neighbours were paying on a much lower scale than himself; and he must decline to continue to pay on his existing assessment. They, however, took no notice of his letters for two years, when they sent him in a demand for nine quarters on the £58 assessment. Originally, it should be stated, they assessed him at £65.

Defendant was then called and stated that the actual amount of the assessment of his house for Queen's taxes was £50, and not £53. He was assessed for poor-rate at £36. For three years he paid the water-rate on a £65 assessment. The house opposite his, which was let for £40 a year, was a better one than his own. He complained of the Company not answering his letters and not sending in the demand-notes for two years. Had they replied to his letter in 1886 in the negative, he would have left his house, because he had made up his mind not to pay on £53; but he obtained no answer, and the result was he could not leave the house now until March, 1890.

Cross-examined: He did not admit that the Company had a right to claim on the gross rental.

Mr. BODKIN observed that one of the Metropolitan Water Companies was entitled to charge upon the gross rental.

Mr. BANNISTER said he must deny that the Company had treated Mr. Alexander with any discourtesy, or had neglected to answer his letters. He had sent a great number of voluminous letters to the Company on the subject, and had rejected their reasonable offer, threatening to place the matter before the Local Government Board; and it was only as a last extremity that they brought the case into Court.

Mr. Simpson was called, and said he occupied the house facing Mr. Alexander's, and only paid a rent of £40 a year for it.

Mr. Prout said he lived at No. 12 in the same row of houses, and paid £45 a year rent. He was summoned under similar circumstances to Mr. Alexander.

The Bench having conferred,

Mr. BODKIN remarked that they had decided to fix the value of the house at £48 a year; and this being so, the Company would have to pay the Court fees.

Mr. BANNISTER: Is that so, Sir, after we have exhibited all this forbearance?

Mr. BODKIN: You have not succeeded.

BARNET GAS AND WATER COMPANY v. HOLDEN.

This was in every respect a similar case to the above.

Defendant, who resided at No. 7, Station Road, East Finchley, admitted that he gave £500 for his house; but contended that he only ought to be charged for water on the scale of the rateable assessment, which was £32.

After some discussion,

The Bench fixed the amount at £40, and gave the Company costs.

NEWBURY CORPORATION GAS SUPPLY.—At the last meeting of the Newbury Town Council, the Gas Committee reported that they had an offer to renew a bond for a loan of £6000 on the security of the gas-works at 3½ per cent. provided it is not disturbed for 7 years. Mr. Lucas proposed the adoption of the report, and said that there was every prospect of the Committee being able to re-adjust their capital at 3½, instead of 4½ per cent. Already they had secured £2300 at the lower rate; and now they had the present offer of £6000. The report was adopted.

THE PROJECTED ELECTRIC LIGHTING OF THE CITY.—At the meeting of the Commission of Sewers last Tuesday, Mr. Treloar asked the Chairman of the Streets Committee when they were to receive the Committee's report on the question of the electric lighting of the City, and why it had been delayed. Mr. Bridgman replied that the Committee had done all they possibly could in the matter. They had decided upon the principle on which the conditions for tendering should be based; and the matter was now with the officers. The Engineer was putting the matter into proper shape; and as soon as this was done, the Committee would be glad to discuss it. They had determined that the matter should be settled before they went out of office, so that before a new Commission was appointed, he (Mr. Bridgman) believed they would be able to report that they had arrived at satisfactory conditions. Mr. Morton—a member of the Committee—expressed the opinion that the Committee had been playing with the question a whole year, and wasting time.

Miscellaneous News.

METROPOLITAN BOARD OF WORKS.

THE PROPOSED ALTERATION IN THE STANDARD OF LIGHT.

At the Meeting of the Metropolitan Board of Works last Friday, the Special Purposes Committee submitted a report, recommending that they be authorized to approach the Board of Trade to urge the early introduction into Parliament of a Bill to provide for the adoption of a new and reliable standard of illuminating power, and for the prescription of a standard photometer, with a view to securing uniformity of result in the testing of gas in the Metropolis.

Mr. J. ABBOTT, Chairman of Committee, in moving the adoption of the report, said that the testing of gas was one of the most important duties entrusted to the Board. This subject of standards of light had been before the Board since 1879. The movers, in the first instance, were the Board of Trade, who, in the year named, referred the matter to a Committee, who condemned the present mode of testing gas. Four years subsequent to that—viz., in 1883—the South Metropolitan Gas Company confirmed the opinion of that Committee, and expressed an opinion that the Board of Works should apply to the Board of Trade, in order to get some alteration in the method. For many years there had been reports frequently made by the Special Purposes Committee of the Metropolitan Board of Works in relation to this matter; but for want of unanimity it was considered by the Board that any attempt to deal with the question would end in parliamentary difference, and probably involve a large expenditure, with but little result. He was glad to be able now to report that the circumstances had entirely altered. A fortnight ago a proposition was made by the South Metropolitan Gas Company to be heard by the Special Purposes Committee by means of a deputation. The Committee were empowered by the Board to receive such a deputation. The Chairman of the Company (Mr. G. Livesey) and one or two of the other Directors, attended by the Chief Engineer of the Company (Mr. F. Livesey), attended a meeting, and put the matter before the Committee, with the result that they were convinced the time had arrived to go to the Board of Trade, with a view to their bringing in a Bill to get an Act of Parliament passed, so as to prevent the sperm candle being any longer used for gas testing. Although the Gaslight and Coke Company had not expressed an opinion, it seemed to the Committee that the representation to the Board of Trade would be almost unanimous; and that an alteration in the present arrangements would be obtained.

Mr. PURDY seconded the motion.

Mr. RICHARDSON said this was a very interesting question, but was very little understood by the public. The point was to substitute a more exact and trustworthy standard of light than the sperm candle, which was at present the only legal standard for the testing of gas. Experiments made had shown that in some instances the sperm candle test was largely in favour of the consumers, while other sperm candle tests showed the very reverse—viz., in favour of the gas companies. The candles were very rarely alike; and the result was that the consumers and the gas companies became dissatisfied. Practically, at the present time, the Act for regulating the lighting by gas of the Metropolis was a dead letter, and wanted thoroughly reconsidering. It was at present a useless expenditure of hundreds of pounds a year for the examination of gas in the Metropolis—in fact it was a simple waste of money.

Mr. JONES thought that, if they approached the Board of Trade, that body would no doubt say, "Be good enough to explain what the new photometer is that you wish to introduce." He hoped the Board would not be so foolish as to go to the Board of Trade as proposed by the Committee, but postpone the matter, and let the great County Council undertake it.

Mr. ABBOTT, in reply, said that had the last speaker been a member of the Special Purposes Committee, he would not have made the observations he had. There was perfect unanimity of opinion between the Board of Trade Referees and the Gas Companies on this motion. The Chairman of the South Metropolitan Gas Company and the others interested were unanimously of opinion that the Committee should ask the Board to go to the Board of Trade. A large amount of money had been expended, and a great deal of time had been given to the consideration of this question. Something like 2000 experiments had been made by the Chemist of the Board (Mr. Dibdin); and in these experiments, he had been assisted by four or five of the Gas Examiners. Therefore this report had not come before the Board without due thought and care. The matter had already been ten years under consideration; and now, when there was a likelihood of getting the question settled, he thought the Board should certainly avail themselves of the opportunity. There was no intention or desire for the standard to be altered either to the disadvantage of the consumers or the gas companies. All that was wanted was to get a reliable standard; the sperm candle being admitted on all hands to be non-reliable and unsatisfactory.

The report was adopted.

SOUTH METROPOLITAN GAS COMPANY.

An Extraordinary General Meeting of this Company was held last Wednesday, at the Bridge House Hotel, Borough, S.E.—Mr. GEORGE LIVESY in the chair—for the purpose of electing a Director in the place of the late Mr. T. Rowland Hill.

The SECRETARY (Mr. Frank Bush) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, this is a purely formal meeting. We are required by our Act of Parliament to fill up all vacancies on the Board by a general meeting, or an extraordinary general meeting if the vacancy occurs at an intermediate period. I do not know that there is anything for me to say on this occasion beyond a word or two in reference to our late colleague, Mr. T. R. Hill. We have lost in him a most valuable Director; a man who was of great service to the Company from his business experience; and a man whom we all highly respected for his personal qualities. He was an admirable Director, and did his duty most faithfully and earnestly, and worked in the most cordial and friendly manner with all of his colleagues. We feel his loss very greatly indeed. We certainly did not expect when, two years ago, we lost another of our Directors—Mr. Gibbs—that there would so soon be a further vacancy. I have now, therefore, simply to say that we have met for the purpose of electing a successor to Mr. Hill. The Company, I am happy to inform you, is in as good and prosperous a position as ever; and I have no doubt whatever that the gentleman who has come forward for election will devote his energies to maintain its prosperity and welfare.

Mr. SHAND said that the matter they had before them was a purely formal one; but still it was one that must be gone through. He had to propose—"That Mr. John Ewart be elected a Director in place of Mr. T. R. Hill (deceased)." He had no personal knowledge of Mr. Ewart; but the previous day a mutual friend gave a good account of him, and assured him that he would make a good Director. The firm of James Morrison and Co., of which Mr. Ewart was the managing partner, was

well known; and he (Mr. Shand) had no doubt he would bring his business experience to bear upon the work he would have to do on the Board of their Company. He supposed Mr. Ewart had not much knowledge of engineering matters; but with the engineering talent on the Board, that was not required. He (Mr. Shand) had himself been a Director of Gas Companies for many years, and knew the duties of a position of this kind; and from what he had heard of Mr. Ewart, he would make a good Director.

Mr. BUTLER said he had much pleasure in seconding the motion, and for the following reasons:—As far as experience of the gas business was concerned, he supposed the Board of their Company was better off than any in the world; for they had at its head a gentleman who certainly was the best authority on gas matters in the world, and then he was assisted by another Engineer who, he had no doubt, was very useful. They had also a gentleman from the Royal Engineers; and then they had a barrister in Mr. Rostron, who, he supposed, occasionally, when the business men of the Board had been trying to take a common-sense view of a thing, and had sailed a little close to the law, had to put them right. Then the only other qualification necessary to make the Board complete was that they should have some thoroughly good business men; and Mr. Mews and Mr. White, he was sure, carried out all that was wished in that direction. Unless he was very much misinformed in the inquiry he had made concerning the gentleman who he hoped—there was not much doubt about it—would be elected to the vacant position, he thought he was just the man wanted to complete the Board. He was a man in the prime of life; he had had considerable business experience; he was straightforward; and he was a gentleman the Directors of the Board would have a great deal of pleasure in working with. He was sure that the present Board worked cordially together; and he should be very sorry if anything should ever be introduced that would disturb this cordiality. In these times, he continued, people talked a great deal about electricity. All the experts he had spoken to about it thought there was some advancement to be made, and that probably there would be a great deal of electricity used; but one and all agreed that it would not be at the expense of gas. If they continued to reduce the price of gas, and keep up its quality, he believed they would be capable of competing with electricity. Most people had not been used to paying a very long price for their illuminating agent. When, however, they came to use electricity, they would find it was a very expensive affair; and he did not think they would afterwards begrudge so much the money for their gas bills when they came to pay them.

The resolution was carried unanimously.

Mr. GROVER said that, having voted for the resolution, he wished to make one remark. Whenever it was necessary—and he hoped it would be some time to come—to make another appointment of this kind, he thought they should select a gentleman who was resident in the Company's district. It was, to his mind, a great disadvantage not having a member of the Board living in the district.

The CHAIRMAN remarked that he had had great experience of resident Directors; and, in his opinion, it was a decided disadvantage for a Company to have Directors residing in the district. He had much pleasure in announcing to Mr. Ewart that he had been unanimously elected a Director of the Company.

Mr. EWART said he had to return his sincere thanks for the honour the shareholders had done him in electing him a Director of the Company. He regarded it as a great honour because he had always considered the South Metropolitan Company to be the leading Gas Company in the world. There were one or two Companies with larger capitals; but in all other respects the South Metropolitan took the lead. Their stock stood at a higher price in the market; their dividends were higher than any other Company's; and, further than that, they charged the lowest price for gas. Beyond this, in the matter of economical manufacture, and in adopting all the most recent appliances for improved production, he believed the Company stood second to none. The position that the Company occupied had resulted mostly from its excellent management. Almost from its commencement, it had had the advantage of having engineers upon the Board. An active member of one of the earlier Boards was a namesake of his; and he served the Company well for many years. Of course, a large amount of work had fallen on the existing Board. The present was a time of great competition in every way; and he was sure the shareholders were all well satisfied with the way in which this competition had been met. In the past few years oil and petroleum had been cheaper than ever before; but against this gas had held its own. In the interval their dividends had been increased, while the price of gas had been lowered. The competition which more immediately threatened them was that of the electric light. He did not think they had cause for any anxiety in the future. They had met competition in the past by supplying good gas at a low price; and as long as they continued on this line, they need not have any apprehension as to the electric light.

This concluded the business of the meeting.

THE DEACON WASTE-WATER METER IN USE AT CHESTER.—At the recent monthly meeting of the Chester Town Council, the Town Clerk read a letter from Mr. E. Lloyd, the Secretary of the Chester Water-Works Company, to the effect that the Deacon waste-water meter system recently undertaken by the Company had now been completed; and since its completion—on the 21st ult.—the supply of water for the entire district has been constant both by day and night, and will continue so in the future. The Ex-Mayor said, as Chairman of the Water Company, he might mention that this was part of a plan that had been carried out in order to make the supply of water to the city as perfect as it could possibly be. It saved water to the extent of nearly one-half; and it would be of advantage in the sewerage works. They had only one-half of the sewage to deal with instead of the whole.

THE SEDGLEY LOCAL BOARD GAS UNDERTAKING.—At the last meeting of the Sedgley Local Board, in replying to a question on the subject, the Chairman (Mr. S. Wilkes, J.P.) said the parishioners had no need at all to have any thoughts that the gas undertaking was not paying. He hoped to make a statement next March, which would, perhaps, be rather pleasing to those people who had said the Board were doing the worst thing for the parish that could be done in taking over the gas-works concern. He was pleased to say that up to the present they had paid their debts and owed no man anything, excepting the loan; and he hoped to be able to hand over to the district rate account a small sum next March. Mr. Hughes remarked that, although the money would be going in reduction of the rates, a good many of the consumers would like perhaps to see a small reduction in the price of gas. The Chairman observed that they must consider the expense the Board had been put to; and he thought that before they could ask for a reduction, the profits of the gas undertaking should be sufficient to cover the lighting of the roads. The people in Lower Gornal and Gornal Wood had, at all events, experienced a change from the old state of things; for a reduction had been effected to them from 5s. 6d. and 6s. to 3s. 6d. per 1000 cubic feet.

THE DUBLIN CORPORATION AND THE GAS SUPPLY OF THE CITY.

The discussion in the Dublin Municipal Council on the 10th inst. on the quality of the gas supplied to the city (a report of which was given in the JOURNAL last week) has elicited from Professor Tichborne a letter, published in the local press, in which he replies to the various statements which were made concerning himself. In regard to the assertion that the supply of gas could be of different quality in different parts of the city, he thought it imperative to get some information from the Secretary of the Company (Mr. W. F. Cotton). To this end, he addressed the following letter to that gentleman:—"It has been openly stated that there are two supplies of gas to the city, and that the gas on the north side might differ from that upon the south, &c. If such were the case, you will, of course, see that it might invalidate recorded tests taken at the testing station in Burgh Quay, as well as any taken in other places. I should, therefore, be obliged if you would officially answer the following questions:—(1) Are there more works than one for the manufacture of gas in Dublin? (2) Does the whole of the gas pass from the works through one trunk main to supply the city; or are there two or more mains proceeding from the works? (3) By any possible arrangement could the gas on the north side differ from the south at any given time?" In his reply to these questions, Mr. Cotton said: "(1) All the gas supplied to the city is manufactured at one and the same works. (2) The whole of the gas manufactured on our works passes through one trunk main to supply the city, from which all the feeders of mains are supplied. (3) The answer to this question is 'no.'" Continuing his letter, Professor Tichborne says: "As regards the mode of conducting my own testings, some statements were made which are entirely erroneous. All my recorded testings for illuminating power are conducted at the testing office at Burgh Quay, as required by Act of Parliament, in the presence of an officer of the Company; and, when taken, the results are signed and handed to the said officer. The instruments at George Street are merely used for my own information, and as a check. I never test two nights running at the same hour; and these examinations are so arranged that they fairly represent the illuminating power at the various hours allowed by the Act (5 to 11 p.m. in winter). I have also to state that from inquiries I have since made, my observations have been the earliest tests officially taken up to the evening of the 12th of December. The Inspector of Public Lighting has given some tests which do not agree with mine. I am not in a position to explain this discrepancy, as I am in ignorance of where or how his tests are made, or with what kind of instruments they are performed. I am sorry I do not meet the Inspector oftener, when, by comparing notes, I might be in a better position to throw some light on the discrepancies. I have never chanced to meet that gentleman at the official testing-station but once during the last 60 visits to the testing-station, which have extended over the past three to four months. I am quite sure, however, when necessary, I shall be in a position to substantiate my returns; and until I have further evidence before me, I must decline to acknowledge that the Inspector's testings carry any weight with them. I have made a suggestion to the Paving and Lighting Committee, which will, I think, if carried out, clear up some points of importance."

The inevitable budget of letters in the local papers from "Ratepayers" and others has followed the discussion in the Dublin City Council alluded to above. One writer, under the *nom de plume* of "A Ratepayer," says: "It must be apparent to the ratepayers, who are the sufferers, that underlying these unseemly squabbles, there is some personal animosity or malignity which ought not to be tolerated in the Municipal Council. I am told that the Paving and Lighting Committee were sick of the subject, and the loss of time spent in wrangling over it, and gladly delegated their powers to a special or some other Committee composed of men who are never likely to settle the question. Would that the Council could see their way, like sensible business men, . . . to call in an independent umpire to settle the matter, and save us from a repetition of scenes calculated to lower our assembly in the eyes of the world, and bring the metropolis into disgrace." "Ratepayer" then goes on to advocate the introduction of electric or large gas-lamps to improve the lighting of the thoroughfares, which, according to his letter, is at present "disgraceful."

Another correspondent—"J. McConnell"—appears to be able to discern a variation of even $\frac{1}{2}$ candle in the illuminating power of the gas burnt in the public lamps. The gist of this gentleman's letter to the newspapers will be found in the reply thereto by Mr. W. F. Cotton, the Secretary of the Gas Company. "Imagination," says Mr. Cotton "works wonders, judging from the letter . . . signed 'J. McConnell.' This gentleman informs us that—'The night before, the streets were illuminated to such an extent that the journey after business to the suburbs, which for some time past was attended with danger, became much less difficult by the aid of the good gas which shone forth from the lamps.' And then he informs us that all those blessings are owing to a 16-candle gas being shed upon the paths. Perhaps it will surprise this gentleman to learn that, according to the reports made by the Inspector of Public Lighting, the difference in the illuminating power of the gas on the night referred to and the previous one amounted to $\frac{1}{2}$ -candle, and that the $\frac{1}{2}$ -candle if applied to the light emitted from a public lamp, consuming 4 feet per hour, would increase the light to the extent of four-tenths of a candle, assuming the Inspector's report to be reliable. Mr. McConnell is to be congratulated on his visionary organs. A gentleman who can detect four-tenths of a candle difference in the illuminating power of a flame in a public lamp, especially when seen through glass besmeared with filth, must indeed have exceptional sight. I fear Mr. McConnell has been carried away by the recent debate in the Corporation; and the evident attempt by some members of that body to cast upon this Company the responsibility for the present wretched condition of the public lighting of the city. Councillor Robinson, for instance, stated that the numerous complaints of the artisans were now easily explained—that the Company were supplying 13 and 14 candle gas for 16. This member of the Corporation ought to have known that what the artisans complained of was the absence of light altogether in the mornings; and being obliged to grope their way through dark streets when going to their daily toil, and that the shopkeepers and others complained of streets being left in total darkness up to a late hour in the evening. Alderman Mulhgan made an attempt to show that the complaints arose owing to the Company neglecting to keep the lamps in repair. The lamps are kept in as good order as heretofore. It is only within the past few months that we have heard complaints of this sort, although up to that period the condition of the public lamps of Dublin would bear comparison for cleanliness with any other public lamps in the kingdom. The fact is the unfortunate overworked lamplighters, who are employed by the Corporation, are taken away from their legitimate work; and, as a consequence, are unable to keep the public lamps clean or in proper order."

Alluding to what it terms the "Gas Question," the *Freeman's Journal* of yesterday week says: "In the course of the last discussion at the Corporation, it was conclusively shown that the city was being cheated out of certain contractual rights and benefits for which it was paying over the

mail. But from the Gas Company's point of view it can be established with equal conclusiveness that this is all a myth, and that the Corporation critics do not understand what they are talking about. The Gas Company, however, does not content itself with crying out 'You're another.' Mr. Cotton, the very efficient Secretary, steps out and challenges the Corporation to prove their charge. 'We have contracted,' he says in effect, 'to perform certain conditions. If we break our contract, we are subject to certain money penalties. You say we have violated that contract. Prove it, if you think so, and enforce the penalties.' This simplifies the question very much, and knits the issue. The only objection to it is that the suggestion involves law proceedings; and law proceedings involve the ratepayers' money, and, accordingly, the independent outsider immediately becomes an interested spectator." Our contemporary thinks that Professor Tichborne's letter does not give the ratepayers much satisfaction, and that it leaves matters very much where they were.

EDINBURGH AND LEITH GAS COMMISSION.

At the Meeting of the Edinburgh and Leith Gas Commission last Wednesday—Provost Aitken (Leith) in the chair—Mr. R. Mitchell was instructed, with a view to allowing the contracts for stores for both the Edinburgh and Leith works to expire at the same time, to arrange with the contractors to the Edinburgh works to allow their contracts to run till Whitsunday, when those of Leith will expire. It was reported by Mr. Mitchell that, from Aug. 1 to Nov. 30 last, there had been made at the New Street works 271,199,000 cubic feet of gas from 27,469 $\frac{1}{2}$ tons of coal and 1370 $\frac{1}{2}$ tons of lime; and by Mr. Linton that, from Aug. 1 to the 5th inst., there had been made at the Leith works 139,834,000 cubic feet of gas from 13,956 $\frac{1}{2}$ tons of coal and 667 $\frac{1}{2}$ tons of lime. The average number of retorts in action during November was: At the Edinburgh works, 454; at the Leith works, 192. Bailie Archibald thought it important that monthly reports from the Engineers should be received by the Commission, embracing the quantity of gas made, the price of coal consumed, and the amount of wages paid. The suggestion was acquiesced in. There was laid on the table a report as to the use of gas as a motive power and heating and cooking agent. Bailie Walcot, in explaining the report, said the Sub-Committee went to Glasgow, where Mr. W. Foulis, the Manager of the Corporation Gas-Works, was kind enough to show and explain all the arrangements in force there. The Glasgow Corporation do not let out on hire heating-stoves, as these were much more liable to depreciate than cooking-stoves; but they sold a large quantity of them at 12 $\frac{1}{2}$ per cent. under list price. They kept a considerable stock of cooking-stoves for sale, also at 12 $\frac{1}{2}$ per cent. under list price; and they also let these out on hire. Reckoning the cost of these stoves, and the expense of fitting them up, they found they had a return of something like 10 per cent. per annum. There was a great demand for the cooking-stoves; and the result had been extremely favourable, so far as the consumption of gas was concerned. It brought the summer demand for gas almost up to the winter consumption. The increase was represented by something like 12 million cubic feet a month; and they felt that they had in this full compensation. He thought that they should do something at once in letting out cooking apparatus. Bailie Archibald remarked that he had some reluctance in embarking upon a business that might interfere with private traders. He was not sure either that there would be the same demand for these stoves in Edinburgh. Bailie Walcot said, as regarded Glasgow, Mr. Foulis expressed not merely his own opinion, but the opinion of tradesmen, when he said that, instead of selling fewer stoves since the Corporation had taken up this work, they sold a great many more. Bailie Turnbull proposed that the matter be remitted to the Works Committee, with power to inquire as to the experience of other companies who had tried the system. This was agreed to. It was stated that the gas-rental from Nov. 14 to the 7th inst. amounted to £21,109, and that the total receipts since Aug. 1 were £48,875. It was also stated that the Commissioners had taken over the consumers' deposits from the Companies, amounting in the case of the Edinburgh Company to nearly £5000; and in the Leith Company, to about £2000.

THE ELECTRIC LIGHTING EXPERIMENT AT LEAMINGTON.

The Leamington correspondent of the *Birmingham Gazette* writes as follows in last Wednesday's issue of our contemporary:—"Very little doubt is now entertained that Messrs. Chamberlain and Hookham's experiments with the lighting of the streets of Leamington by electricity will come to an end next year. It will be remembered that those gentlemen, who are trading under the title of the Midland Electric Light and Power Company, last year laid down a plant at the Royal Spa, at a cost of upwards of £30,000. The Corporation agreed to lay on the current to their public buildings, and also to pay the Company £400 a year for lighting the Parade and Bath Street. These thoroughfares have been lighted by 183 16-candle power incandescent lamps. Dissatisfied with the effect of this arrangement, the Corporation two months ago asked Messrs. Chamberlain and Hookham to make experiments with alternative systems. They met the Local Authority in a very liberal spirit, and set up the arc system, the "Sunbeam" lamps, and the 25-candle power incandescent lamps. It has now been ascertained that the annual expense to the borough of lighting the Parade and Bath Street by the respective systems would be as follows:—Twenty arc lamps, at £42 each, £840; 30 "Sunbeam" lamps, at £30 each, £900; 90 25-candle power lamps (after the pattern of those now on trial in Bath Street), £600. The present contract price for the supply of electricity to the specified area is £400 a year. The amount previously paid to the Gas Company for lighting the two thoroughfares was less than £200 a year. In view of the disproportionate increase in the cost of electricity as compared with gas, it is believed that, at their meeting on the 14th prox., the Leamington Corporation will give the required twelve months' notice to determine the supply of the current to the public lamps."

The General Purposes Committee of the Leamington Corporation, which consists of the whole of the members of the Town Council, held a special meeting last Tuesday, to consider the electric lighting on the Parade. The ex-Mayor (Mr. John Fell), who was largely instrumental in introducing the electric light at Leamington, presided as Chairman of the Committee. The Parade and Bath Street, from Christ Church to the railway bridges, have for about twelve months been lighted by 16-candle incandescent lamps; but they were considered so unsatisfactory that, for the last five weeks, experiments have been made with arc lights of 3000-candle power, "Sunbeam" incandescent lamps of 300 candle-power, and lamps of double the power of those ordinarily in use. The arc light was considered too unsightly, and not a good example; and the only light the Committee could approve was the "Sunbeam." But the terms of the Midland Electric Light and Power Company for these lamps were considered to be simply prohibitive. The Committee accordingly decided to recommend the Town Council to take steps to determine the existing contract with the Company, which can only be done by giving twelve months' notice. The incandescent lights, though they have failed to give satisfaction for street purposes, answer remarkably well, it is said, for shops, shop

windows, and public buildings in the town where they are used. The managers of the Company recently stated that they cared very little whether the Council continued the use of electricity for street purposes; but the decision now come to will mean a loss of about £400 a year to them.

ELECTRIC LIGHTING MATTERS IN PARLIAMENT.

In the House of Commons yesterday week, Mr. Howarth asked the First Commissioner of Works whether, during the ensuing recess, he could see his way to make such an extension of the electric lighting arrangements in the House as would check further injury to the stonework in the corridors and staircase leading from the Star Court to the Commons lobby; and whether it would be possible to carry the electric light into the different rooms connected with the Reporters' Gallery. In reply, Mr. Plunket said he quite agreed in the desirability of the objects sought by his honourable friend; and he had under consideration a scheme for extending the electric lighting of the building, which would include and go somewhat further than the suggestion made by Mr. Howarth. The cost, however, of the installation would be considerable; and he (Mr. Plunket) must obtain the opinion of the Treasury upon its financial aspect. He feared it would not in any case be possible to complete the arrangements earlier than Easter. Sir J. Swinburne inquired whether the right honourable gentleman was aware that the electric light had been so dim in the library that members had had to use candles as auxiliaries. Mr. Plunket thought it must be very seldom that candles were used. He had never seen them in the library.

On Thursday, Mr. Watt asked the President of the Board of Trade whether the Electric Lighting Act of 1882 precluded the Board of Trade or local authorities from granting Licences to one or more persons, firms, or Companies to light the same area; whether the Act contained restrictions as to the breaking up of any street without the written consent of the Board of Trade; whether inquiries are made by the Board of Trade as to the ability of undertakers to carry out the work before Licences are granted; whether he could state what number of Licences had been granted since the last return was issued; and whether it was a fact that the reason assigned by companies which obtained Licences under the Act of 1882 for abandoning these was the enormous law costs which would have been incurred owing to the opposition of the local boards or councils. In reply, Sir Michael Hicks Beach said that the Electric Lighting Act, 1882, did not preclude the granting of Licences to one or more persons, firms, or companies to light the same area. With reference to the second question, the Board of Trade could not give power to break up streets except under a Licence or Provisional Order. As regards the third question, inquiries such as those suggested by the honourable member were made by the Board of Trade. Two Licences had been granted since the last report to Parliament. As to the last part of the question, he said that no such reason as that referred to by the honourable member had, to his knowledge, been assigned for the abandonment of Licences.

On the same evening, Sir Henry Roscoe put a series of questions to the President of the Board of Trade bearing on the same matter. He inquired whether his attention had been called to notices given for supplying electric light in the parish of Kensington by the four following Companies:—The Kensington and Knightsbridge Electric Company, Limited, the Chelsea Electricity Supply Company, Limited, the Notting-hill Electric Lighting Company, Limited, and the House-to-House Electric Supply Company, Limited; whether he was aware that these Companies proposed to conduct their operations mainly, or very largely, within the same area, and in many instances to take power to break up the same streets and places; whether it was the duty of the Board of Trade, before granting any Provisional Order, to take cognizance, of its own motion, of such *prima facie* objections; and whether the Board would not take any cognizance unless and until it was moved thereto by the local authority, or other parties interested. In reply, Sir Michael Hicks Beach said the answer to the first three questions of the honourable member was "Yes;" and to the last, that it is the duty of the Board of Trade, in framing a Provisional Order, to consider any objections to which their attention is called, and also any such as may occur to them.

Sir George Campbell, also referring to the applications now being made by various Companies to supply Kensington and other parts of the Metropolis with electric light, on Thursday, asked the President of the Board of Trade if he would take care that concessions were not sanctioned till the applicants had given some substantial guarantees that they would really carry out the proposed works, and not merely hawk about the concessions in the market, and throw them up if no profit was made there, as was so generally the case when Provisional Orders were granted under the former Act. Sir Michael Hicks Beach replied that in all Provisional Orders and most Licences, clauses were introduced providing for the deposit by the undertakers of an annual sum; and the powers so given could not be transferred without the sanction of the Board of Trade.

METROPOLIS WATER SUPPLY.

Messrs. Crookes, Odling, and Tidy, in the course of their report to the Official Water Examiner of the Metropolis (General A. de Courcy Scott), on the quality of the daily samples taken of the water supplied to London during November, say: "Despite the swollen and unfavourable state of the rivers during the past month, the condition of the water supply to the Metropolis, derived both from the Thames and the Lea, has continued excellent. It is the admitted character of river-derived water to vary in composition, although for the most part within a very small range, from week to week and month to month; and although it is satisfactory to know that during times of heat and drought, when the maintenance of a high standard of excellence in drinking water is more especially called for, the state of the river as a source of supply is at its best, it is hardly less satisfactory to observe, by means of adequate storage reservoirs and filter-beds, how slight, for the most part, is the influence, upon the character of the water supply, of the less favourable condition of the river prevailing in rainy seasons. Although somewhat reduced by the results recorded during the month of August, the mean standard of purity for the four preceding months was decidedly high; and notwithstanding the altered condition of the river during the past month, in only one particular do the results obtained differ appreciably from the mean results of the previous four months; and that particular—viz., the degree of freedom from colour-tint when subjected not to mere inspection, but to the exact determination afforded by the colorimeter—not one of any weighty significance. As regards the proportion of organic matter present, as measured by the determination of the organic carbon, the mean result for the month furnished by the Thames-derived supplies, was 0.164 part of organic carbon in 100,000 parts of the water, as against a mean of 0.159 part for the previous four months, during which time, moreover, the maximum proportion met with during the past month, or 0.191 part in 100,000 parts of the water, was in several instances attained and exceeded. In the case of the East London Company's water derived from the Lea, the difference was in the same direction, and to a similar insignificant extent; the mean amount of organic carbon for the month being 0.155 part in 100,000 parts of water, as against a mean of 0.148 part for the previous four months."

NOTES FROM SCOTLAND. (FROM OUR EDINBURGH CORRESPONDENT.)

EDINBURGH, Saturday.

The Edinburgh and Leith Gas Commissioners' meetings are of interest on account of the circumstance that so many gentlemen have been suddenly placed in the responsible position of having the control of the valuable property connected with artificial lighting; and it is only to be expected that now and then some "original notions" should be ventilated by the Commissioners in their new position. There has not been much of that sort of thing, possibly on account of the precaution of having all ordinary business first considered in Committee; but there have been one or two instances. A few weeks ago several of the Commissioners made a good deal out of the method of selling coke; but whether it was popularity for themselves, or capital for the Commissioners which they were seeking, is a question I decline to answer. They took exception to a contractor buying several thousand tons of coke for their works at from 5s. to 6s. per ton, while poor people purchasing in hundredweights were charged as high as 10s. 6d. An attempt was also made to create a quite unworthy feeling in the Commission against selling the coke to strangers, and particularly against giving a stranger a large order at a lower figure than that at which a local gentleman had obtained a much smaller order. These questions, of no great value in themselves, were treated with so much warmth that a remit to a Committee was necessary to enable the points raised to be coolly considered. This process has now been gone through; and at Wednesday's meeting the Committee's report resolving to sell coke on the best terms obtainable—the normal rate being 7s. a ton—was agreed to without comment. That is to say, the good sense of the majority of the Commissioners prevailed, and they have resolved, in the matter of coke at least, to conduct their concern on business principles, and not as a benevolent institution which is not the object of their existence. This resolution did not interfere with the one which immediately followed, and which is in every way exceedingly appropriate—viz., to distribute 1000 tickets entitling the holder to a hundredweight of coke for 3d. If on no other ground, this is a commendable practice on account of its being a good advertisement of the Commissioners' coke.

The Dundee Gas Commissioners made an official inspection of their gas-works last Thursday. The Engineer (Mr. J. M'Crae) conducted the party over the works; and everything was found in good order. Attention was directed to the employment of tar for firing steam-boilers, in connection with which it was explained that for this purpose a ton of tar is equal to 2 tons of coal. The regenerator furnaces—an adaptation by Mr. M'Crae of the Siemens furnace—were found to be giving excellent results; and the much-talked of air-process of purification was also explained. The inspection lasted fully an hour and a half; and at its close, Lord Provost Hunter, on behalf of his fellow Commissioners, expressed their thorough satisfaction with the condition of every department of the works, not only in regard to the means at the disposal of the staff for the manufacture of the large quantity of gas now being made, and for carrying on the relative work, but on the method, order, and cleanliness everywhere observable. The output of the works is at present 2,400,000 cubic feet per day.

Last Sunday morning, damage to the amount of nearly £1000 was done to the building of the Heriot-Watt College in Edinburgh, the origin of which is believed to have been the fusing of an electric light wire. The College which was only opened this year, was lighted by electricity at a cost of more than £2000. On Saturday night only a portion of the building was lighted; and it is surmised that the extra strength of the current passing through the wire leading to the apartments which were occupied had resulted in the fire.

(FROM OUR GLASGOW CORRESPONDENT.)

GLASGOW, Saturday.

The proposal on the part of a majority of the Glasgow Corporation Gas Committee to take from the past year's gas surplus a sum of £3000 and apply it to the general purposes of the Corporation, has already raised some opposition outside the Council. At a recent meeting of the Fifth Municipal Ward Committee, the Secretary was instructed to request the ward representatives to oppose the motion when it comes up for discussion, as it was considered that the funds of one Trust should be applied to the benefit of the ratepayers directly interested in the Trust; in other words, that the gas consumers should get all the benefit that can result from surplus profits made by the gas undertaking.

The Town Council of Coatbridge, at their last meeting, had under consideration a report from the Fire and Lighting Committee, in which it was stated that they had had an interview with Mr. Wilson, Secretary and Manager of the Gas Company, regarding the terms of a new gas contract. He stated that the Directors of the Company had offered to supply gas for the street lamps, &c., by average meter, at 3s. 9d. per 1000 cubic feet. After full consideration was given to the matter, however, the Committee resolved to recommend that the Council should take in hand the lighting and extinguishing of the lamps themselves. Mr. Sharp explained to the Council that after the Committee had drafted their report, the Directors of the Company had, at an interview, agreed to take off 2s. 6d. per lamp, and do the lighting, cleaning, and storing, which would reduce the charges to 32s. 6d. and 37s. 6d. per lamp. The Committee, however, had previously decided on doing the lighting and cleaning after December themselves, as they believed it would be cheaper. The next thing was the number of meters to be fixed; and it was thought by the Committee that there should be one meter for every twelve lamps, but the Directors wanted a meter for every ten lamps. For each meter the cost would be £1 10s. On the motion of Bailie Gilchrist, it was remitted back to the Committee to come to an amicable settlement in regard to the meters; it being understood that the contract with the Company was only to be renewed in so far as the supply of gas was concerned.

The Royal Burgh of Renfrew seems to be getting deeper and deeper into the mire with regard to its gas supply, which is in the hands of the Town Council. There was lately a very serious difficulty with the supply, inasmuch as on a recent Friday, there had been burned over a period of 24 hours, 52,100 cubic feet of gas; so that on the Saturday morning the amount of gas left was only 3000 feet. On the suggestion of the Provost, it was remitted to the Gas Committee to look into the matter of gasholder accommodation, and see what could be done to improve it, and report to the Council. It may be remembered that several years ago the Renfrew municipal authorities made overtures to the Glasgow Corporation Gas Committee to contract to extend their gas-mains to Renfrew and supply the town with gas. Already the mains extend to the burgh of Govan and to Linthouse, where there is a large shipbuilding and engineering establishment, with a considerable resident population. The proposal was not entertained by the Glasgow Gas Committee. For the present, therefore, the town must continue to be in a bad way in respect of its gas supply, and help must come from itself, or from the adjoining burgh of Paisley, which perhaps might entertain such overtures as those which were made to Glasgow.

THE ACCOUNTS OF THE AIRDRIE AND COATBRIDGE WATER COMPANY.—In the House of Commons last Wednesday, Mr. Donald Crawford gave notice that he should ask the Lord Advocate on Saturday whether his attention had been called to a report by Mr. J. Muir, C.A., on the accounts of the Airdrie and Coatbridge Water Company, in which it was stated that the Directors had levied rates exceeding those authorized by Parliament, and adopted a method of accounts which deprived the ratepayers of a reduction of rates amounting to upwards of £5000; whether any contradiction or explanation of the above statement had been given since the report was published on Nov. 17; and whether he will inquire into the matter, and consider what remedy can be afforded to the ratepayers.

DESTRUCTION OF A TAR DISTILLERY BY FIRE.—Last Wednesday night, a disastrous fire occurred at Cardiff, resulting in the total demolition of the large tar distillery works belonging to the Cardiff Collieries Supply Company. The fire, it is supposed, originated in the boiler-house; and within a very short time the whole works was one mass of flame. In it were large tanks filled with some thousands of gallons of naphtha and various oils. In one large tank were 3000 gallons of creosote; and between 500 and 600 tons of resin in bulk were stored in the yard. The Dock and Town Fire Brigade were speedily on the spot; but they were absolutely powerless to do anything. The damage is estimated at from £10,000 to £15,000.

THE WATER SUPPLY OF PONTEFRAC AND DISTRICT.—At the last meeting of the Pontefract Town Council, it was reported that the wells were now yielding 96,346 gallons of water per day. A letter was subsequently read from the Castleford Local Board inquiring the terms on which the Corporation would supply their district with water when the new scheme proposed was carried out. In reply, the Corporation offered a supply at 7d. per 1000 gallons. The Finance Committee recommended that under the Borough Extension Act, 1865, the Corporation should apply for a Provisional Order to extend their borrowing powers from the present limit of £23,352, in order to supply adjoining districts with water, and for extending the water-mains. This proposal was agreed to after some animated discussion.

THE PROPOSED ELECTRIC LIGHTING SCHEME OF THE DUBLIN CORPORATION.—At the meeting of the Municipal Council yesterday week, the Town Clerk read a letter from the Special Committee appointed to consider the question of the Corporation undertaking electric lighting in the city.

The letter described the present position of the matter, and submitted that as the Gas Company were no longer proceeding for a Provisional Order, it would probably be found more expeditious and less expensive for the Corporation to seek powers for supplying electricity for public and private purposes, either by an extension of the Licence now about to issue, or by seeking a new Licence. Mr. Robinson, Chairman of the Public Lighting Committee, moved the adoption of the letter. The Committee, he said, were in doubt whether they should proceed by Provisional Order or obtain powers by means of a Licence. The latter would only be available for seven years; but an Order would be unlimited as to time. If they took the seven years' Licence, they would not be able to make as good terms with the contractors as if they had the Provisional Order; but, on the other hand, an Order would entail petitions against the Corporation, and a contest over the matter. An Order, before it took effect, would also have to be confirmed by Act of Parliament; while the Licence could be obtained at much less expense, and could be renewed when the seven years had expired. Mr. Mayne, M.P., seconded the motion, and it was adopted.

THE WATER SUPPLY OF HYTHE.—The Hythe Town Council met on Monday last week to take into consideration the terms of the Bill intended to be introduced into Parliament next session for various powers; the most important object being to acquire, compulsorily or by agreement, the Black Rock Spring. In reply to several questions, the Town Clerk (Mr. G. Wilks) made a long statement, in the course of which he said the Black Rock Spring yielded 50,000 gallons every 24 hours; and the level of the water was sufficient not only to supply the Seabrook portion of the borough, but also to a very large extent to give a constant supply to every house in the town without the aid of machinery. They were bound to provide a water supply for the new portion of the borough which was springing up at Seabrook; and he stated that the gross estimated rental of the houses in that district amounted to considerably over £900 a year. At the present time Seabrook was supplied by the Sandgate Local Board, under an agreement which could at any time be terminated at one month's notice. Various clauses in the proposed Bill were considered; and one authorizing the Council to enlarge their present borrowing powers for the purposes of the Bill, and the purposes of their water-works undertaking generally, was carried. The clause authorizing the Council to levy rates and charges for the purposes of the Bill was also carried; and eventually it was decided that the corporate seal be affixed to the necessary preliminary petition.

GWYNNE & CO., ESSEX STREET WORKS, VICTORIA EMBANKMENT, LONDON, W.C. GWYNNE & BEALE'S PATENT GAS EXHAUSTERS & ENGINES.

Telegrams: "GWYNNEGRAM, LONDON." Telephone No. 2698.

Exhausters of nearly all sizes in Stock.

Prize Medals at all the Great International Exhibitions.

Exhausters equal to a total capacity of more than 26,000,000 cubic feet passed per hour have been supplied by us.

Our new Patent Non-Fluctuating Exhausters, to work without the slightest oscillation or variation in pressure, are strongly recommended.

MAKERS OF EVERY DESCRIPTION OF HYDRAULIC AND GAS MACHINERY.

Gwynne & Co.'s New Catalogue and List of Testimonials can now be obtained on application.

Exhausters and Vertical Engine as supplied for both the Fulham and Bromley-by-Bow Stations of The Gaslight and Coke Company.

We supply only the very highest quality of Machinery; and our Exhausters are constructed of large size to run at slow speeds.

OXIDE OF IRON.

O'NEILL'S Oxide has a larger annual sale in the United Kingdom than all other Oxides combined. Purity and uniformity of quality guaranteed. Pamphlet, "How to Purchase Bog Ore," to be obtained on application. Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C. JOHN WM. O'NEILL, Managing Director.

ANDREW STEPHENSON, Agent for the Gas Purification and Chemical Company, Limited, Palmerston Buildings, Old Broad Street, London, E.C.

CANNEL COAL, &c.

JOHN ROMANS & SON, EDINBURGH. Gas Engineers, supply all the most approved SCOTTISH CANNELS; also FIRE-CLAY GOODS, CAST-IRON PIPES, and other APPARATUS for GAS AND WATER WORKS. Prices, &c., will be forwarded on application to No. 30, ST. ANDREW SQUARE, EDINBURGH, } Scotland. No. 54, BERNARD STREET, LEITH, }

SULPHURIC ACID, B.O.V., for Sulphate of Ammonia Making. Guaranteed clear, of full strength, and to produce a fine white-coloured salt. Delivered in carboys or railway tank wagons. For prices and terms address **BALE, BAKER, AND CO.**, 120 & 121, Newgate Street, LONDON.

TIMMIS & CO., of STOURBRIDGE

Make only the best quality of FIRE-CLAY RETORTS, BRICKS, TILES, & LUMPS. Also SPECIAL SILICA BRICKS, to stand great heats. All descriptions kept in Stock. For Prices apply to **JAMES LAWRIE AND CO.**, 63, Old Broad Street, E.C., Sole Agents for London and District. Telegraphic Address: "EIRWAL, LONDON."

ALEX. WRIGHT & Co., 55, 55a, and 56, MILLRANK STREET, LONDON, S.W. [Telegraphic Address: "PRECISION LONDON."] Makers of Wet and Dry Gas-Meters, Station Meters and Governors, Photometers, and Gas-Testing Apparatus, Test Gas-holders and Meters, Registering and other Gauges, &c., &c. * See Advertisement on Page III. of the Wrapper of last week's issue.

W. C. HOLMES & Co., Huddersfield, AND 80, CANNON STREET, LONDON, Contractors for Gas-Works complete, Makers of Gas-holders, Purifiers, Scrubbers, Condensers, Retort Fittings, &c., Improved Valves, Engines, and Exhausters. Also for Collingwood's Regenerative Retort-Settings. * See Advertisement on p. III. of Wrapper of this week's issue. Cablegrams: "Ignitor London." Telegrams: "Holmes Huddersfield."

ACETATE OF LEAD BOOKS.

TEST Papers and Solutions for Gas- Works prepared by **R. D. Gibbs**, Summerfield Crescent, Birmingham. Analysis of Coal, Oxide, and all Gas Materials.

IRISH BOG ORE OXIDE OF IRON.

GAS PURIFICATION.

BALE, BAKER, & CO., direct Importers from Ireland. Sample and Price on application. Spent Oxide and Sulphate of Ammonia purchased. 120 and 121, NEWGATE STREET, LONDON, E.C.

TUBES.

FOR Gas, Steam, and Water; Galvanized, White Enamelled, and Hydraulic Tubes and Co. JOHN SPENCER, Globe Tube Works, WEDNESBURY; and 14, Great St. Thomas Apostle, LONDON.

SULPHURIC ACID.

JOHN NICHOLSON & SONS, Chemical Works, LEEDS, specially produce this ACID for making SULPHATE OF AMMONIA of high quality and colour. Highest References and all particulars supplied on application.

HUTCHINSON BROTHERS, Barnsley, Gas Engineers and Contractors, Makers of Gas-Meters and General Gas Apparatus, Sulphate of Ammonia Plant, Tools, and Sundries. * See large Advertisement in last week's issue, page 911.

FOR SALE—A Tar and Ammonia Works in Yorkshire. Well situated for obtaining Tar and Liquor. Terms easy. Address Box 25, Post Office, HECKMONDWIRE.

TO CHEMICAL MANUFACTURERS & OTHERS.

TO LET—Extensive Premises, situate between Wrexham and Rnabon, on a Branch of the Great Western Railway, consisting of Large SHED, 167 feet long by 25 feet wide; BUILDINGS, 37 feet by 28 feet; 67 feet by 27 feet; and 25 feet by 20 feet; WHARF, 500 feet long, with Railway Siding running the whole length. Within easy access, by rail, of several large Gas-Works.

Apply to GEO. E. WOODFORD, RUABON.

SITUATION Wanted as Fitter in a Gas or other Works. Twenty years' experience in Lead and Iron Pipe Fitting. Can put in Mains and Services, Fix Meters, House Fittings, Gas-Stoves, Repair Lamps, and do General Repairs at Works.

Address JOHN KEMP, 60, Cannon Street, Blackpool, LANCASHIRE.

INSPECTOR.

WANTED, by the Richmond (Surrey) Gas Company, a competent Man as INSPECTOR. Candidates must have had good experience in Main and Service Laying, Inspection and Testing of Meters, and the general outdoor work of a Gas Company.

Applications, in own handwriting (accompanied by not more than three recent testimonials), stating wages required, age, and present employment, to be addressed to the ENGINEER, Gas-Works, Richmond, SURREY.

SHEFFIELD UNITED GASLIGHT COMPANY.

WORKS SUPERINTENDENT.

WANTED, by the Directors of this Company, an experienced and competent Man to act as SUPERINTENDENT at their Effingham Street Gas-Works.

He will be required to reside on the Works; House, Coal, and Gas free. The maximum make of Gas at this station is about three-and-a-half million cubic feet per day.

Applications, stating age, previous engagements, and salary required, to be made by letter only, addressed to Sir Fredk. T. Mappin, Bart., M.P., Chairman of the Company, Gas Offices, Sheffield, not later than Monday, the 7th of January, 1889.

Testimonials not to be sent till asked for.

HAMBURY THOMAS, General Manager.

Commercial Street, Sheffield,
Dec. 14, 1888.

GAS EXHAUSTERS WANTED.

THE Gas Committee of the Bingley Improvement Commissioners hereby invite Manufacturers of Exhausters to TENDER for the Construction and Erection of a Set of DUPLICATE EXHAUSTERS at their Gas-Works.

Form of tender, &c., to be had from the undersigned.

By order,
GEORGE DUNBAR MALAM, Engineer.

Dec. 17, 1888.

RAMSGATE CORPORATION.

(GAS AND WATER DEPARTMENT.)

THE Committee invite Tenders for the supply of a STATION METER, to pass 40,000 cubic feet per Hour, with 14-inch Slide-Valves and Connections, and Bye-pass.

Tenders to be sent in not later than Tuesday, Jan. 1, 1889.

The Committee do not bind themselves to accept the lowest or any tender.

Full particulars on application to

WILLIAM A. VALON, Engineer.

BOROUGH OF DARWEN.

(GAS-WORKS DEPARTMENT.)

TENDERS FOR PURIFIERS.

THE Corporation are prepared to receive TENDERS for the Supply and Erection of Three New PURIFIERS, each 25 feet by 30 feet, with Pillars and Girders complete. Also the REMOVAL of one of similar size, from one building to another.

Plans and Specifications may be seen, and all necessary information obtained from the Gas Engineer, Mr. Thos. Duxbury, Charles Street, Darwen.

Sealed tenders, endorsed "Tender for Purifiers," to be delivered at my Office, on or before Nine a.m. on the 31st of December.

The Corporation do not bind themselves to accept the lowest or any tender.

By order,

CHAS. COSTEKER, Town Clerk.

Town Clerk's Office, Darwen,

Dec. 5, 1888.

BRISTOL UNITED GASLIGHT COMPANY.

AMMONIACAL LIQUOR.

THE Directors of this Company invite TENDERS for the purchase of the AMMONIACAL LIQUOR to be produced at one or either of their three Stations during a period of One, Three, Five, or Seven years, commencing on the 1st day of July, 1889.

The annual quantities and strengths of the Liquor produced at each of the Stations at present are approximately as follows:—

	Gallons.	Strength.
Canons' Marsh Station,	1,000,000	of 14 ounce
Avon Street	1,300,000	" 15 "
Stapleton	700,000	" 17 "

Conditions of Contract, and forms of tender, may be obtained on application to the undersigned, to whom also tenders, sealed, and endorsed "Tender for Ammoniacal Liquor," must be delivered not later than Ten a.m. on Monday, the 28th day of January, 1889.

The Directors do not bind themselves to accept the highest or any tender.

JAS. V. GREEN, Secretary.

Chief Offices: Canons' Marsh,
Bristol, November, 1888.

OXIDE OF IRON.
